Duties of Medical Officers of Health and other Sanitary Officers.—Every sanitary sub-officer shall, by inspection of the district for which he is appointed, keep himself informed in respect of any nuisance existing therein that require abatement under the Sanitary Acts, and if he shall receive notice of the existence of any nuisance within the district, he shall, as soon as practicable, visit the place and inquire into such alleged nuisance; and when he finds any matter demanding, in his opinion, attention from the medical officer of health of the dispensary district in which the same occurs, he shall notify it forthwith to the medical officer of health in writing, specifying the nature of the case, the situation of the premises, and the name of the occupier or owner, in the form (A) in the schedule B to this order annexed, and shall preserve a copy thereof in duplicate, and he shall submit to the sanitary authority, at each weekly meeting, the duplicates of the reports which he has made to the medical officer of health during the preceding week, or an abstract thereof, and he shall also report to the sanitary authority any other matter affecting, or threatening to affect injuriously, the public health within his district.

Every medical officer of health who shall have been apprized officially by the sanitary sub-officer, or shall otherwise become cognisant of any matter demanding his attention as aforesaid, shall, as soon as practicable, visit the place, and if, after due inspection, he finds such matter to involve danger to public

Digitized by Google

health, he shall report thereon to the sanitary authority, in the form (B) in the said schedule B, showing the source from which he received the information, and the date thereof, and the date of his visit of inspection; he shall also give a sufficient description of the nature of the case, and the remedy which he recommends to be adopted, and shall preserve a duplicate of every such report.

Every medical officer of health shall inform himself, as far as practicable, respecting all influences affecting or threatening to affect injuriously the public health within the district in his charge, and shall from time to time, as occasion may require, report on the subject to the sanitary authority, and recommend the measures which, in his opinion, should be adopted for the protection or improvement of the public health in such district.

Every consulting sanitary officer, if such an officer be appointed for the sanitary district, shall attend meetings of the sanitary authority, whenever required to do so, and shall advise them on all matters and proceedings requiring medical knowledge and advice in the administration of the sanitary laws.

Every medical superintendent officer of health, if such an officer be appointed for the sanitary district, shall discharge all the duties imposed by this order on the consulting sanitary officer, and in addition to such duties shall perform the following duties—that is to say, he shall report monthly to the sanitary authority on the general sanitary condition of the rural sanitary district, and on the discharge of their duties by the medical officers of health and sanitary sub-officers of the district.

Every medical officer of health and sanitary sub-officer of the union shall attend meetings of the sanitary authority, whenever required to do so, and shall assist in all proceedings in which his assistance may be required.

Every medical officer of health, and every other officer appointed under this order, shall, in matters not specifically provided for in this order, observe and execute the instructions of the Local Government Board and all the lawful orders and directions of the authority applicable to his office.

Statistics of Disease.—It shall be the duty of the medical officers of health and of the consulting sanitary officer or medical superintendent officer of health, if such an officer be appointed to the sanitary district, to furnish to the Local Government Board such statistical returns of sickness and disease as shall from time to time be required from them respectively.

We do not need to point out that the duties herein set forth, are onerous and important, and that, if the system were to be really worked efficiently, there would be plenty for the officers to do, deserving of liberal payment; but it will be observed that not a syllable is said respecting a salary for these duties, and it is not pointed out that the new Act has created new duties which should be rewarded by additional salaries, nor is any information or instruction whatever given to the sanitary authorities respecting the change of the law which hitherto bound them not to vote to the medical officer of health a higher salary than one-fourth of his dispensary salary, and which now permits them to assess such salary without limitation, in accordance with the merits of each individual case. The Local Government Board did, in fact, issue a circular to each sanitary authority in which they required a return of the "additional salary now proposed to be paid to the dispensary medical officer under Section ii. of the Public Health Act, 1878, as medical officers of health," but hastened immediately to explain, by a separate circular, that no salary need be granted "additional" to that sham remuneration which the medical officer has hitherto received for refraining from sanitary zeal.

These official pronouncements of the Board, and the obstructive policy of which they are the expression, have produced their effect, and the Irish sanitary authorities have accepted the hint with alacrity, and unanimously decided either to let previous salaries stand, or to reduce the miserable pittances which the law has hitherto obliged them to vote. But the discussions which have arisen on this subject are instructive, and we only wish that our legislators were as well read in the literature of the matter as we are obliged to be. With one voice the sanitary authorities of Ireland have declared the Irish Public Health Act to be a sham, and its working (which the Local Government Board annually presents in rose-colour tint), to be a farce; and the feeling is loudly expressed that the pitiful dole which these authorities pay to thei rmedical officers of health, does not produce any useful result. Little as we sympathise with the sanitary authorities, we must concur with them in this opinion, but we cannot recognise their right to grumble. The guardians and the Local Government Board receive as much as they pay for, and all the Acts of Parliament and sealed orders which they may promulgate will never get more than this from the medical profession. These authorities and the central department have deliberately set themselves to nullify the sanitary law of the country, and on them, not on the medical officers of health, lies the blame of their success in the effort. The dispensary medical officers of Ireland have always been both ready, able, and willing to put the sanitary law into execution and they are so still, and we cast back upon these who now plead the unsuccess of the system, the responsibility for that unsuccess.

We shall return to the subject for the purpose of showing by documentary proof that the medical profession is absolutely free from blame in this matter, that it did its duty against all discouragements and only ceased from its activity when disheartened by the discouraging attitude of those who ought to have been most active in the matter.

Prof. A. Ladenburg, of the University of Kiel, makes the important announcement that he has succeeded in accomplishing the first step towards the artificial production of atropine, by recombining the primary products of the decomposition of the natural alkaloid.

Dr. Starke in the (*Berl. Klin. Wochensch.*), recommends as a superior method, especially for children, to mix castor oil with coarsely grained sugar, until it forms a thick dough, which may be flavoured with powdered cinnamon or other aromatics. One part of oil requires about three parts of sugar. Children take this without hesitation. In place of sugar, the *Pulvis Glycyrrhizæ Compositus* may often be used with advantage, as it increases the action of the oil. It is best to allow the dough to become stiff by placing it on ice for a short time.

Phare's method for the treatment of colic consists in *inversion*,—that is, simply in turning the patient upside-down. Colic of several days' duration has thus been relieved in a few minutes. The patient may take the elbow-knee position, or may lie (face down) on the edge of the bed, with his head and shoulders hanging down. Complete inversion, however, is best. The mechanical aid, in giving vent to gases, is perhaps the most efficient element in the cure.

Notes on Current Topics.

Senile Deafness.

A STUDY of the limit of perception of musical tones by the human ear, is to be found in a reprint by Dr. Laurence Turnbull, of Philadelphia. His original experiments prove that increasing age surely diminishes the acuteness of perception of tones. This diminution, he believes, is not due simply to senile thickening of the membrana tympani, but also to a gradual narrowing and change of shape in the auditory meatus, together with alterations in the middle ear, diminution of conducting power of the bones, and diminished susceptibility of the auditory nerve, incident upon advancing years.

Results of Treatment in Vienna.

THE Philadelphia *Medical Reporter* considers that the modern treatment of disease in Germany has greatly deteriorated since the days of Niemeyer. Theorising, histology and diagnostic refinements have taken the place of the effort to cure disease by rational empiricism. Witness the next to worthless therapeutics in Ziemssen's "Cyclopædia." A Vienna correspondent in the Canada *Medical and Surgical Journal* gives some striking statistics. In Bamberger's clinic of 27 cases of pneumonia, 17 died; 24 per cent. of all cases of typhoid fever die; facial erysipelas is "frequently fatal," &c. It looks as if medical science in Germany was running to seed.

Ear Boxing.

A CORRESPONDENT of the Philadelphia *Medical Reporter* writes as follows:—No one form of punishment is so dangerous as boxing the child upon the ear. Not only is injury to the organ of hearing often produced, but inflammation of the brain frequently follows, and death has been the result.

In the family, this matter of injurious methods of punishment is not by any means beyond our influence, if we will but take pains to inform people upon the subject.

If corporeal punishment is allowed at all in schools, its use ought to be carefully guarded. No teacher should be allowed to punish a child by rudely jerking it about, by striking it anywhere upon the head, or with any instrument whatever, except it be flexible and with smooth edges. These requisites are best fulfilled by a rubber strap with rounded edges.

The Editor of the *Reporter* adds, We have had within the last six months two cases of partial deafness under our care, both distinctly traceable to punishment by "boxing the ears."

Abnormal Appetite.

IN the Australian *Medical Journal* Dr. Fulton publishes the case of a girl who, when six years of age, discovered a singular taste for feeding on slugs, beetles, cockroaches, spiders, and other repulsive insects. The taste remained for several years.

The subject of this abnormal appetite was carefully brought up; was a member of a family of 13 children, in no one of whom did a similar *penchant* betray itself; there was no trace of insanity in any known relatives of the family on either side of the house. The girl was remarkable for an extremely aimable disposition; was perhaps below medium in intellect. She was of slight but perfect physique, and her appetite became perfectly normal about the age of 14.

Pharmaceutical Prosecutions in Ireland.

WE published recently a report of the prosecution of two persons instituted by the Irish Pharmaceutical Society because they had compounded medicines without legal qualification, and because one of them had deliberately appropriated the title of "member," he being nothing of the sort. We think it desirable to refer to the matter in order that we may congratulate the pharmaceutic profession upon this vindication of their legal rights, and on the fact that they possess an executive which is willing to protect them and the public from the roguery of pretenders. We think that the circumstances of these cases fully justified the action of the Council of the Society, and that they performed an obvious duty in their enforcement of the law against unqualified dispensers which Parliament entrusted to them. We sincerely wish that we could felicitate our own profession on a similar happy state of affairs. We have a law against unqualified and uneducated practitioners. We have, every day and all day, the unconcealed infraction of that law by quacks as obscene as they are ignorant, and by counter-prescribers as self-asserting as they are uneducated. We have also a Supreme Council supposed to administer the law, and to protect the public from the incursion of traders in quackery. But, unhappily, our Medical Council lacks the *esprit de corps*, the energy and the appreciation of public and professional necessities which the Irish Pharmaceutical Council displays. Whatever of intelligence our governing body can boast of is devoted to the art of excusing themselves for neglect of their functions, and as a substitute for such intelligence and activity we find ourselves obliged to be content with stilted respectability and aristocratic "repose."

We are unqualifiedly envious of the Irish Pharmaceutical Society, and only wish that it were possible for us to exchange a few of the oracular expositors of the General Medical Council for the common sense, industrious, business men who manage the affairs of the Irish pharmaceutists.

Appointment of Dr. Grimshaw as Registrar-General for Ireland.

WE are much gratified to inform our readers that the Lord Lieutenant has appointed Dr. Thomas Wrigley Grimshaw as the successor of Dr. Malachi Bourke in the office of Registrar-General for Ireland. Upon the wisdom of such a choice by Government there is really no second opinion in the profession, and no one is disappointed or censorious except, perhaps, the few obscure politicians who coveted the office and the wire-pullers of certain clubs who put these gentlemen forward for a position which they were palpably incompetent to fill. It is not discourteous towards the many medical men who might well have been elected as Dr. Bourke's successor to say that any of them was second to Dr. Grimshaw in the attainments and qualities specially adapted to the functions which he has to discharge. He is an excellent writer,

Digitized by Google

thoroughly conversant not only with the theory and political economy of state medicine, but with the law which regulates its practice in Ireland, and with the day-to-day practical requirements of sanitation. He is an excellent and reliable statician, and will bring to his duties a character for industry and energy which, we confidently hope, the proverbially relaxing effect of public service will not dull. The new Registrar-General took a Moderatorship in the University in 1860, is a Doctor of Medicine and a Diplomate in State Medicine of "Old Trinity," as well as a Fellow of the Irish College of Physicians. He is Physician to Steeven's Hospital and Lecturer on Medicine in that School; and, having served the usual term as Physician to Cork Street Fever Hospital, is now its consultant. As one of the Hon. Secs. of the Hospital Sunday Council he has done most excellent service, which, if he possessed no other quality, would give him a title to public reward.

It is most satisfactory to note the apparent intention of the Irish Government, as represented by the Lord Lieutenant, to recognise special merit rather than political fussiness. Considering the extreme importance of the duties to be discharged by the Registrar-General, we feel truly thankful that this system of selection has secured for Ireland a public servant who really knows his business, and is willing and able to do it.

A Remarkable Case of Malpractice.

THE *New York Hospital Gazette* gives the history of one of the most extraordinary procedures which has come to its knowledge. A patient affected with anchylosis of the cervical vertebræ falls into the hands of a homœopath who evidently possesses about as much knowledge of his profession as an old woman. The deformity caused by the anchylosis is so great that the patient's head touches his chest. The physician, or, rather, attendant, accepts the patient's diagnosis of "rheumatism," concludes that the trouble is in the muscles, and advises an operation for the removal of the deformity. On the appointed day the patient is etherised, and his body and shoulders bound to the table by bandages. Additional bandages having been applied to the head, traction was made on these with all the strength that two men could exert, until the neck was straightened. During the pulling, sudden cracking noises were heard twice, but this caused no alarm to the surgeons (?) present, who continued their efforts, and finally succeeded in taking a human life by breaking the man's neck. The ancholysed union was fractured, and the patient died on the table.

If (says the *Hospital Gazette*) cases such as this do not incite the people to insist upon a higher standard of attainments for those to whom their lives are entrusted, we do not believe that college conventions, societies, or learned addresses delivered periodically by men connected with diploma mills will have the slightest effect. The case referred to gives evidence of the grossest ignorance and most barefaced assumption on the part of a person duly accredited an M.D. by the State laws. It is thus proven that the law fails to properly provide for the lives of the people by granting a licence to practise to men of this stamp, who, in defiance of all knowledge of anatomy, surgery, and pathology, apply the rude principles of mechanics to correct the deformities of a fellow-creature. We should expect more from a barbarian, about as much from an idiot.

The German Society of Public Health

(*Verein für öffentliche Gesundheitspflege*) is now in Session, at Stuttgart, from the 15th to the 17th. The subjects for discussion are—1. Methods of Disinfection. 2. Measures for Preventing the Introduction of Contagious Diseases from Foreign Countries. 3. The Hygienic Requirements of Boarding and Lodging Houses. 4. The Necessity of Erecting Public Mortuaries. 5. The Management of Public Bathing Establishments.

A Novel Test for Insanity.

IN the *Vierteljarschrift für Gerichtliche Medicin*, July, Dr. Westphal reports the case of a murderer who was alleged to be partially insane. Among the tests was the administration on two occasions of sufficient brandy to make him quite drunk. In this condition of intoxication he plied him with a number of questions, believing that if his delusions were simulated he could not keep up the deceit when so much in liquor. As the man still persisted in his insane statements, the expert concluded that he was really demented.

Animal Vaccination.

DR. PISSIN, of Berlin, has published a report covering fourteen years of the progress of the "Institute for Animal Vaccination," in that city. It is full of valuable information on the subject. In the last four years the percentage of successes in primary vaccinations were 97 per cent.; in re-vaccinations 74 per cent.

A Model Irish Guardian.

A CO. Louth "squireen," named Carraher, thus expresses his views in the Dundalk Board of Guardians:—

"The Acts of the English Government have been to put burdens on the tax-payers which they are not able to bear—forcing upon them what they did not want, and keeping from them what they really required. The Government do this, to use the words of Jefferson, 'by creating a brood of lazy officials who are eating up all the substance of the industrious citizens and reducing them to a state of poverty.' *All the medical Acts and all the sanitary Acts tend to this purpose.* It was said the doctors could not live on reduced salaries, but of whom are the medical officers generally composed? They are in most cases sons of small farmers or struggling shopkeepers, who have to make great efforts to give their children an education. But when those children get a black coat on their back and a horse to ride they cannot live without increased salaries, and he regretted that this system of increasing salaries had been indulged in by that board for many years."

We advise the Irish Government to study the address of this person, and to learn therefrom the sort of stuff to whom they entrust the lives and deaths of the sick poor of Ireland. We cannot be much surprised at the rank filthiness of the normal Irish cabin when we learn, from

Digitized by Google

the mouth of one of those whose business it is to look after their cleanliness that "all the medical Acts and all the sanitary Acts tend to nothing but to create a brood of lazy officials." But probably this orator knows more by personal experience or family tradition than we do about life in an Irish cabin; at all events, it is plain that "a black coat on his back and a horse to ride" does not bring with it either sense or good taste for the descendants of "small farmers or struggling shopkeepers."

Colour Blindness.

A GOOD many letters have appeared during the past few days in the daily papers upon colour blindness, and the dangers likely to arise amongst those employed on railways, and seafaring people from ignorance on the subject. It is not, perhaps, so generally known as it should be that in January, 1877, the Board of Trade issued instructions that candidates for masters' and mates' certificates should be subjected to a test examination as to their ability to distinguish colours. A return issued recently shows that the number of candidates who failed to pass the test between May, 1877, and May 1879, was 39. Of that number, however, 12 passed upon re-examination, and one was allowed to have passed without any further examination. In four cases the patients were unable to distinguish colours, and in one case no particulars were given. Green was in 25 cases described as red, in 5 as yellow, in 6 as blue, and in 5 as other colours; red was in 12 instances described as green, three times as blue, and once as another colour; yellow was mistaken for green eight times, and for red eleven times; blue was confounded once with green, once with red, and once with yellow; black was twice taken for green, and twice for red; and white was twice described as green.

The Hospital Saturday Fund.

WHAT we stated last week with respect to the increase in the street collection reported at the head office is borne out by the West and South-west Suburban and the West Ham Local Committee, both of which show an advance, the former being £107 6s. 5d. as against £94 0s. 1d. last year, and the latter £30 13s. 2½d. as against £17 13s. 10½d., last year. The total amount now received at South Place is £1,588 12s. as compared with £1,370 10s., last year. Amongst the large amounts at present received are—Eley, Brothers, £30.; Surrey Commercial Docks, £36 17s. 2d.; Siemens, Brothers, £32 0s. 5d.; J. Mowlem and Co., £30; Atlas Chemical Works, £19 11s. 3d.; Prebble and Morley, £12 2s. 6d.; Hon. H. C. Eliot, £5; Shand, Mason, and Co., one-half from the firm and one-half from the employès, £20 10s. 4d.

Irishmen in the Cabul Embassy.

SIR LOUIS CAVAGNARI, besides being connected on his mother's side with the Montgomerys of Belhavel and the Blackers of Carrickblacker, in the co. Armagh, was married to the daughter of Dr. Graves, of Cookstown, Dungannon; and Dr. Ambrose Kelly, Physician to the Embassy, was son of Mr. Russell Kelly, of the Solicitor's Office, Board of Works, Dublin, and was a Licentiate of the Irish Colleges of Surgeons and Physicians. Lieutenant Hamilton was son of Alexander Hamilton, J.P., of Inistiogue, county Kilkenny, and nephew of Mr. Henry Alexander Hamilton, of Balbriggan.

The Treatment of Dental Periostitis.

M. MAGITOT has just made an important contribution to the therapeutics of periostitis about the roots of teeth, in the *Bull. de la Société de Chirurgie.* In 1820 Delabarra, a French surgeon, drew a tooth which was the cause of a fistula, cut off a portion of its root, and replaced it successfully. A similar operation was done in 1853 at Montpellier, and in 1870 Messrs. Coleman and Lyons, of St. Bartholomew's Hospital, London, published fourteen cases treated in this manner, with nine successes. Since that time a number of French surgeons have performed the operation, and in 1878 Dr. David collected and published twenty new cases with only one failure. Magitot, performing the first in 1875, has now done it sixty-three times, with five failures.

The diagnosis is easily made, for it is usually indicated by distinctive and well-marked lesions, such as inflammation or abscess on the alveolar border of the face, denudation and partial necrosis of the maxilla, and fistula upon the mucous or cutaneous surface. The local pathological condition is periostitis and caries at the apex of the root of a tooth, with destruction of the bulb and its vascular connections. The therapeutical indication is the removal of the diseased portion of the tooth. Occasionally it has been possible to do this by introducing a pair of Liston forceps through a large alveolar fistula and cutting off the affected portion of the tooth, but the cases in which this can be done are very rare.

This treatment is usually unsuccessful in those cases in which the pus has made its way to the surface alongside the tooth, the failure seeming to be due to the alteration or destruction of the periosteum in the line of the fistula, and the constant diminution of the surface by which the new adhesions must be formed. The ages of M. Magitot's patients ranged from sixteen to fifty-five years, and in about three-fourths of the cases he filled the cavities in the teeth before replacing them.

A Brave Act.

AT a special meeting of the Governors of the Ballinasloe Lunatic Asylum, the resident medical superintendent reported the "brave and praiseworthy conduct of attendant Costelloe, who, at the risk of his own life, saved that of one of the patients. This patient got on the top of the ball court wall, and precipitated himself from it to the ground, a height of 30 feet. Costelloe saw the patient was apparently going to commit suicide when he got on the wall, so he got under the wall, and caught the man in his descent, thus saving his life at imminent danger to his own." The Board granted Costelloe a sum of £3 for his bravery.

A Riot among Lepers.

THE great Leper Asylum at Mahaica, in British Guiana, has recently been the scene of a riotous outbreak. The necessary stringency of the rules of the establishment, both for the sake of the unfortunate patients, as well as

Digitized by Google

for the sake of the colony at large, has led to frequent difficulties with some of the inmates. The doctor in charge of the Asylum, Dr. Hillis, was attacked while on one of his usual rounds, and forcibly imprisoned in one of the rooms, and a leper armed with a razor, kept guard over the door, while the others fell on the officials and servants, and threatened to murder them. Fortunately an alarm was raised, and a large body of police despatched to the assistance of the besieged officials, who had to take refuge in the varions rooms and lock themselves in. A hand-to hand fight ensued, during which the female patients showed even greater ferocity and determination than the men. They were, however, fortunately, unable to find any dangerous weapons, and were eventually overpowered.

The Degree of Heat fatal to Tænia and Trichina.

Professor Edward Perroncito, of Turin, communicates to the *Boston Med. and Surg. Journal* the results of an extended series of experiments on the degree of heat fatal to parasitic helminths and their germs. The cysticerci and scolices of various species of tænia, the trichina free and encysted, the filaria, the strongylus, &c., were made the subjects of careful and repeated observations. He found that they died, without exception, before the temperature of the liquid containing them reached 50° Cent., equal to 122° Fahr. The point of elevation which proved fatal with remarkable uniformity was 48° C., or 118.4° F. Five minutes' exposure to a temperature of 50° C. he regards as invariably fatal. The experiment of swallowing the cysticercus after exposing it to that temperature was tried by a number of courageous students, without ever producing a tænia. A much higher temperature has been generally supposed to be necessary for the purpose.

Dr. D. J. Lyne has been appointed a Justice of the Peace for the county of Cork.

Yellow Fever is again showing itself alarmingly at Memphis; last week there were 132 fresh cases, and 48 deaths.

In the Army Medical Service, Surgeon-Major C. G. Irwin and Surgeon-Major W. R. Wall have been gazetted to retire on half-pay temporarily.

Notice has been already given that an Examination of Candidates for twenty-four appointments as surgeon in Her Majesty's Indian Medical Service will be held in February, 1880.

The Professorship of the Practice of Medicine has become vacant in the Queen's College, Galway, by the resignation of Dr. Colhan, senior, and candidates are requested to send their testimonials to Dublin Castle on or before the 28th instant. The candidate who may be selected will have to enter on his duties on the 1st November.

The rates of mortality, per 1,000 last week in the principal large towns were—Portsmouth 11, Sheffield 14, Bristol 14, Bradford 15, Glasgow 15, Brighton 16, Birmingham 16, Hull 16, Wolverhampton 17, Oldham 17, Leeds 17, Newcastle-upon-Tyne 17, Edinburgh 18, Salford 18, Nottingham 19, Manchester 19, London 20, Plymouth 22, Leicester 23, Sunderland 23, Liverpool 24, and the highest rate 26 in Dublin and Norwich.

The death-rate from the seven principal zymotic diseases averaged 4·0 per 1,000 in the large towns last week. The deaths referred to diarrhœa in the twenty towns, which had steadily increased from 47 to 343 in the seven preceding weeks, declined last week to 293; the annual death-rate from this disease which averaged 2·1 per 1,000 in the 20 towns, was equal to 5·5 in Norwich and 5·8 in Leicester. Small-pox caused 7 more deaths in London, 9 in Dublin, but not one in any of the other large towns. Scarlet fever showed the largest proportional fatality in Leeds, Manchester, Nottingham, and Sunderland.

Scotland.

(from our northern correspondent.)

Health of Edinburgh.—The deaths in Edinburgh, for the week ending the 6th inst., amounted to 75, the rate of mortality being 18 per 1,000. Three deaths from fever were registered in the Old Town, and four deaths from whooping-cough, one of which occurred in the New Town. Of the 146 births 5 were illegitimate,

Glasgow—Unprecedentedly Low Death-Rate.—The death-rate of Glasgow for the week ending the 6th inst., was at the unprecedentedly low rate of 14·5 per 1,000. During the same periods of 1876, '77 it was 21, and in that of 1878, 19. The nearest approach to this low rate was for the first week of last month when it was 15.

Edinburgh Dispensary for Women and Children.—This dispensary has completed its first year of work, having been opened, twice weekly, since the beginning of September, 1878. The report which is signed by Mrs. Masson, the hon. secretary, and the balance sheet by Mrs. Russell, hon. treasurer, show that the attendance has steadily and largely increased, till at the end of the year it averaged from thirty to forty patients each day. The whole number of patients attending during the year has been 681; the whole number of visits paid, 2,464; and of prescriptions given, 3,942. Out of the whole number of patients only twelve have been found unable to pay the charge of threepence for medicine required at each visit, but these payments have by no means been sufficient to defray the drug bills incurred. Hitherto Dr. Sophia Jex Blake has been the only medical woman on the staff, but the executive committee have just appointed Dr. Agnes Maclaren as a second attending medical officer. They have also decided, after consultation with many of the more intelligent patients, to place the dispensary henceforth, on a "provident" basis; that by small contributions, payable in health as well as in sickness, the patients may themselves provide for the expense of the institution. Honorary members subscribing to the funds will also receive tickets in proportion to their contributions, and in this way the benefits of the dispensary may be extended to those who could not themselves pay the required subscription. The consulting staff of the dispensary—the President of the College of Surgeons, Dr. G. W. Balfour, Dr. Angus Macdonald, and Dr. Peel Ritchie.

REGISTRAR-GENERAL'S WEEKLY RETURNS.—The returns of births, deaths, and marriages in the eight principal towns of Scotland for the week ending Sept. 6th, say :—The death-rate in the eight principal towns during the week ending Saturday, Sept. 6th, 1879, was 16·1 per 1,000 of estimated population. This rate is 2·1 under that of the corresponding week of last year, and 1·0 under that of the previous week of the present year. The lowest mortality was recorded in Greenock, viz., 12·2, and the highest in Perth, viz., 25·4. The mortality from the seven most familiar zymotic diseases was unusually low, being at the rate of 2·5 per 1,000, or 0·6 under the rate for the previous week. Acute diseases of the chest caused 52 deaths.

SUSPECTED YELLOW FEVER AT GREENOCK.—On the 11th inst., a Norwegian barque, named the *Fingal*, arrived at the Tail of the Bank from Wilmington, bound for Glasgow. A communication was forwarded to the Sanitary Office, at Greenock, to the effect that one of the seamen was affected with what seemed very like yellow fever. Mr. MacKay, sanitary inspector, and a medical man went on board, and the patient was, in the course of the evening, sent to the Greenock Infirmary. The vessel being bound for Glasgow, Dr. Russell, of Glasgow, was communicated with.

NEW ROYAL INFIRMARY, EDINBURGH.—A movement has been set on foot by the members of the Edinburgh, Orkney, and Shetland Association, having for its object the raising of a fund in the islands for the purpose of furnishing a ward in the New Edinburgh Royal Infirmary.

Literature.

GEHEILTE HUNDSWUTH BEIM MENSCHEN. (a)

1. WE have bracketed these two brochures together, the one by a foreigner, and the other by a British subject, as they offer a marked contrast.

Most singularly the German writer has not only read the latest literature on the subject of rabies, but liberally acknowledges the labours of others, and the sources from which some of his information has been drawn, whilst the English writer has, as we shall show, liberally borrowed from the most recent works on hydrophobia, with but scanty avowal of his indebtedness. Both writers, moreover, direct the attention of the profession to the use and value of curara as a remedy in the treatment of hydrophobia, but with this great difference, that Dr. Offenberg has practically tested the drug he writes about, whilst Dr. McNeile simply presents his readers with an abstract of the chapter published in the *Medical Press and Circular* in 1878, in our reports on "Rabies and Hydrophobia." If we call this a coincidence, it is a most strange one.

For the present we leave Dr. McNeile, and confine ourselves to the German pamphlet.

Readers of the *Medical Press* are already familiar with the name of Dr. Offenberg, as we published a full account of the case of hydrophobia treated by him with curara, and we had subsequently in our pages, a communication from him, to correct the mistake about the name of Dr. Polli, which, by some mischance, became associated with his case, so that it was generally believed that two cases of hydrophobia had been cured by this poison; one in Italy, the other in Germany. In the July number of the *Practitioner*, there is a full account of the tracing of the mistake.

In the pamphlet under notice, Dr. Offenberg has republished full particulars of the very interesting case which he was fortunate enough to treat, and as a contribution to our knowledge of curara his brochure is extremely valuable.

After a full account of his observations, he enters on the question as to whether the patient was really suffering from lyssa humana, and we believe there can be no doubt that his diagnosis was correct. As a proof of Dr. Offenberg's literary honesty, we have but to point to pages 30, 31, 32, 43, 45, where he acknowledges both the work done by the *Medical Press and Circular*, and the labours of George Fleming, thus, as we have said, presenting a contrast with the compiler, Dr. McNeile.

As one instance, we may allude to the appreciation of Fleming by the German and British writers. Dr. Offenberg thus says, in acknowledgment of a quotation from Fleming: "Veterinararzt Fleming. Herausgeber von the "*Veterinary Journal*," welcher, 1872, ein sehr erschöpendes und als *classisch gerühmtes werk* "Rabies and Hydrophia" veroffenlichte gilt in England als grosse Autorität auf dem Gebeite der vergleichenden Pathologie."

This is a candid expression of opinion which will be shared by every reader who has perused Fleming's work.

Dr. McNeile, at page 36, for the first time introduces the name of Fleming "as a veterinary authority, and the author of a book on Rabies," after presenting his readers with information, nearly all of which may be found in Fleming's now classical work. This is but one instance to which we may allude *en passant*, as it illustrates the difference between the two writers.

Dr. Offenberg, with candour, quotes from the *Medical Press and Circular* the account of the suggested use of curara by Professor Sewell and Waterton. He makes one quotation in English, to which he does not exactly agree, and which shows how closely Dr. McNeile has followed our lead.

Dr. Offenberg directs attention to the following remarks (p. 93, second edition of "Rabies or Hydrophobia"), and we place it side-by-side with a paragraph from Dr. McNeile's treatise.

"The poison is so deadly, moreover, that its use necessitates the most anxious care, not only with regard to patient, but operator as well, and, indeed, all who come in contact with it, for if the merest scratch is touched with it, the consequences may be of the gravest kind. . . . The syringe should be used for curara alone."—*Medical Press and Circular*, 1877.

"Considering its activity, great caution should be exercised both in administering curara and watching its effects. The medical attendant should take particular care to avoid wounding himself with the needle of his syringe, and the instrument should not be used for any other purpose during the illness."—McNeile, p. 99, 1879.

Dr. Offenberg points out that other poisons are used which are equally as dangerous as curara, and that this should not be a deterrent against the employment of the drug. We have to congratulate him on the true scientific spirit in which he has received and valued "our contribution to the literature of hydrophobia."

2. It is very hard to define plagiarism. Such a thing does exist, and though it receives a more respectable a name, yet, by those who call a spade a spade, literary piracy will always be known by its true title. We do not accuse Dr. McNeile of this offence, but we may point out that there is a singular resemblance in the tone and arrangement of his treatise on Hydrophobia, to that adopted by the writers Fleming and Dolan, who prepared the reports of the *Press and Circular*, both of whom published their works prior to the publication of Dr. McNeile's brochure. The most superficial glance at the three books will confirm this. When we come to look at the special chapters, we are all the more struck by this similarity. We may safely say that there is little new in this pamphlet, which evidently bears the mark of hasty compilation, as we find the name of one of the most eminent French observers, M. Bouley is spelt Bowley, and Valleix spelt Valleux, and at p. 35 the following passage, in which there is a word evidently left out.

"Instances of supposed spontaneous rabies in the human were reported much more frequently." In the human what! Dr. McNeile in his directions on curara, tells us "that subcutaneously it acts best." What other way would he administer it?

We need not enlarge on all the points of resemblance between our own reports and the one under consideration; but may refer to the chapter on pathology; to the method of contrasting tetanus and hydrophobia; to the chapters on treatment; and particularly to the references on curara, &c.

(a) 1. "Geheilte Hundswuth beim Menschen." Ein Beitrag Zur Kenntniss des Curare. Von Dr. Ad. Offenberg. Bonn: Verlag Max Cohen and Sohn (Fr. Cohen). 1879.

2. "A Treatise on Hydrophobia." By J. P. McNeile, M.D. London: Renshaw. 1879.

Digitized by Google

In the latter chapter Dr. McNeile refers to the case of Dr. Polli, reported in the *Paris Medicale*, and which first appeared in English in the *Medical Press and Circular* of 1877. We subsequently corrected the mistake about this case, and we have referred above to it.

We are disposed to be charitable, as we expressed a hope that our reports would stimulate inquiry, and would prove useful to other workers in this field.

We are sufficiently satisfied on this point, and we are also glad to notice that a more hopeful tone is taken from the key-note we struck, as the following passages prove :—

On May 1st, 1878, the *Medical Press* said :—"We consider a more hopeful tone in reference to curative treatment would be justifiable. "Having certified cases of recovery, we may reasonably look forward to still further triumphs over the ravages of this disease, and we have no doubt that rabies will be controlled with as much certainty as dilatation of the pupil is controlled by belladonna or atropine, or contraction produced by Calabar bean, or its alkaloid, eserine."	In May, 1879, Dr. McNeile writes :—"The curative treatment of hydrophobia is still a dark subject; but we are not without warrant for hoping that it will eventually be controllable. "Certain drugs undoubtedly exert an influence over the duration and manifestation of the diseases, and their action encourages us to hope that we only require to discover means to recover vital force to effect a cure." (p. 22).

It is evident our words have had some effect. We cannot devote any more space at present to point out the various passages which closely resemble some in Fleming's work, and in which the suggestions are nearly alike.

We have said enough, and have proved by comparison that with altered words an abstract of the report of the *Medical Press and Circular* has been made without acknowledgement, whether intentionally or intuitively, we do not say.

VEALE'S NOTATION CASE-BOOK. (a)

THE object held in view by the writer of this book is a good one, and it is unfortunate, therefore, that the innate laziness of the majority of mankind should deprive his labours of the benefit they might, but for this besetting sin, confer. We feel quite certain that the ordinary student will not be found to endorse Dr. Veale's assurance, that "a very little attention to the directions and explanations appended to each of the following headings will render the use of the note-book perfectly easy." Our opinion will gather weight when we add that the "directions and explanations" include nearly eight pages of abbreviations which must be committed to the memory of him who aspires to the use of this case-book; and further, four and a-half pages of intricate signs more terrifying in appearance than the most complicated stenographic symbols must be conned and understood. It were vain, we repeat, to expect the average student to fit himself to use this little book as it ought, and it can be added, deserves to be used. The arrangement is undoubtedly good, abstractly, and could the scheme sketched out by Dr. Veale be brought into general employment, it would, without question, tend to accuracy of diagnosis, and skill in treatment beyond that now common. But the necessary preliminary labour of acquiring the art of using a vast number of symbols and abbreviations is a fatal bar to the extended usefulness of the work.

Medical News.

Indian Medical Service.—The Military Secretary, India Office, presents his compliments to the Editor of the *Medical Press*, and begs to enclose for publication a list of the candidates of Her Majesty's Indian Medical Service who were successful at the competitive examination held at Burlington House on the 28th August, 1879, and following days. 39 candidates competed for 16 appointments, afterwards raised to 17. All were reported qualified.—Medical Department, India Office, 10th September, 1879.

REPORT ON THE MINERAL WATERS MANUFACTURERS BY MESSRS. HAMILTON, LONG, AND CO. (LIMITED), DUBLIN.

By CHARLES R. C. TICHBORNE, LL.D., PH.D., F.C.S., M.R.I.A.,

Lecturer on Chemistry, Carmichael College of Medicine; Chemist in Apothecaries' Hall of Ireland; President of the Pharmaceutical Society of Ireland, &c.

Kali Water.—The kali water contained in the imperial pint nearly 30 grains of bicarbonate of potash, with an excess of carbonic acid gas. It was highly aerated.

Lithia Water.—This specimen contained a little under 10 grains of carbonate of lithia in the imperial pint. It was free from calcium salts, and was dissolved in an excess of carbonic acid gas.

Soda Water.—This water contained in the imperial pint 10 grains of bicarbonate of soda. It is highly aerated.

Seltzer Water.—This specimen was very faintly alkaline, owing to the presence of a small quantity of carbonate of sodium. Its main ingredient is chloride of sodium, with traces of magnesian chloride.

Lemonade.—This aerated beverage contained 34 grains of solid matter per fluid ounce. It consists of products from the lemon sweetened with sugar, mainly the essential oil and citric acid. It is perfectly free from lead—an impurity frequently found in this and similar drinks.

Ginger Ale.—This preparation gave 35 grains of extractive matter to the ounce, consisting of citric acid, sugar, ginger, and other flavouring essences.

It will be observed that all the above mineral waters are genuine, and contain the special ingredients appertaining to their names. The kali and lithia waters represent the respective Pharmacopœial preparations in strength, and are therefore reliable remedial agents. So-called soda water is frequently merely aerated water. In the soda water examined we have a proper antacid preparation in keeping with its name.

The source of the water from which these mineral waters are made is evidently fairly pure, because they were carefully examined for albumenoid ammonia, and were found to be practically free from that substance. Albumenoid ammonia is now viewed as one of the most important indications of sewage contamination.

The mineral waters were carefully examined for lead and other poisonous substances; and were found to be perfectly pure in this respect. This poisonous metal has been found in large quantities in some specimens of lemonade.

A PECULIAR MICROCOCCUS IN GONORRHŒAL DISCHARGE.

IN the *Centralblatt für Med. Wis.*, July 12th, Dr. Albert Neisser, of Breslau, announces the discovery of a peculiar form of micrococcus in gonorrhœal pus. It is circular, or oval in outline, not coloured by indulin or methylgreen, usually in colonies of ten, twenty, or more, surrounded by a membrane, generally found on the upper surface of the pus cells, rarely on the epithelium cells.

Dr. Neisser found these bodies in the gonorrhœal discharges of both sexes, in acute and chronic cases, and in various cases involving the eyes. He believes they are characteristic of the disease, though he does not express himself positively on their pathological significance.

BRAIN MATTER LESIONS IN THE INSANE.

In the annual report of the Utica Lunatic Asylum, N. Y., the superintendent makes the following important observation on the results of his autopsies :—

"In regard to the pathological affections of the ganglionic elements of the nervous centres, it seems that the so-called pigmentary degeneration resulting from the absorption and deposition of material in the protoplasm of the ganglion cells, furnished by the decomposition of emigrated red blood corpuscles, is of far more import than has hitherto been admitted. Especially in the brain of paretics it can be demonstrated that this pathological process may lead to a complete destruction of the ganglion cells, to a transformation into granular, dark-brown coloured masses, with disintegrated prolongations resembling the former cell body only in the raw outlines."

THE REMOVAL OF MOLES.

For these unsightly marks Mr. B. Godfrey recommends acid nitrate of mercury. His plan is to take a fine-pointed glass tube, and having dipped it in the caustic solution, to dot all round the hirsute mass, upon the healthy skin, where they both join ; then to dot points through the mass, like the white squares upon the chess-board, leaving the blank ones to be treated in a similar manner in a fortnight hence.

NOTICES TO CORRESPONDENTS.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

To Deans and Registrars.—In a few cases we have not yet received the latest information and prospectus for use in our Annual Educational Number; we shall therefore feel obliged to those gentlemen who have not furnished them kindly to do so by first post.

"Ambulance."—An admirable conveyance for the sick to hospital has recently been provided by the Sanitary Authority of Pembroke Township, Dublin, upon the recommendation of Dr. Chapman, Medical Officer of Health. It is a four-wheel carriage for one horse, containing a canvas-stretcher, upon which the patient is removed in the *recumbent* position ; the stretcher, being movable, is brought to the bed-side of the patient, and the patient lying on it is carried to the ambulance and placed in it. Upon arrival at the hospital the patient is carried to the bed-side, all the time lying in the recumbent position. There is but one stretcher, as only one person should be removed at a time ; but there are two seats inside the ambulance at the side of the stretcher, in case of need for two attendants to accompany the patient. The carriage is, we are informed, well suited for removal of patients to hospital ; there is nothing in it in the way of a textile fabric likely to retain infection, save the canvass-sheeting of the stretcher : immediately after use it is disinfected, as required by section 140 of the Public Health Act. The carriage referred to was constructed by Messrs. H. E. Brown & Co., of Redmond's Hill, Dublin, and cost £80, It is well suited to the purpose; and we believe that a proper and suitable conveyance could not be obtained at less cost in Dublin. The plans may be seen at Messrs. Brown & Co.'s establishment, or the carriage itself at the office of the Pembroke Commission at Ball's Bridge, Dublin.

Pater.—You will find all the information you require on reference to our Students' Number next week.

The Ant-pest in Houses.—As a remedy for this nuisance, from which so many are suffering this year, Dr. Samuel Barker, of Brighton, writes : Those troubled with these pests should apply with a brush a hot strong solution of alum to every chink and crevice infested. Two such dressings will probably suffice to destroy the nests.

Literate.—It would be manifestly unfair to give the information, and would, moreover prejudicially affect the interests of the parties concerned.

Mr. Richardson.—Will find the subject referred to in our issue of July 30th.

Mr. Biddle.—Most important.

Dr. Williams.—Probably in our next number but one.

(A. Foundling), History of Hospitals.—The best information on the subject is to be had in Oppert's and Miss Nightingale's books, and an article in the *Brit. and For. Med.-Chir. Review* of 1864. If a history of foundling hospitals is needed, Mr. Wadsworth's (of the Irish L.G.B) *brochure* will be useful and interesting.

Unprofessional Advertising.—A member of the ladies' committee of the Dublin Orthopædic Hospital, Usher's Island, Dublin, whose inquiry would have more force if she had signed her name to her letter, sends us a copy of an advertisement in which a patient returns thanks in the columns of a Dublin daily paper, for the successful cure of his child "in the National Orthopædic Hospital, Adelaide Road, Dublin." Our correspondent requests our opinion whether such a method of advertising is "legitimate or otherwise." In our opinion such an advertisement would be far from "legitimate," and would certainly be "otherwise" if it emanated from, or was in, any way countenanced by the managers of the institution in question. But we do not feel ourselves justified in assuming that these managers were responsible even by cognisance, and if we are required to hold a balance as to the relative reprehensibility of various forms of advertisements, we would say that such an announcement as that to which our correspondent objects, is less objectionable than the circulation of deformity pictures in hotels and clubs.

L. E. G.—The Local Government Board of Ireland will *not* permit a dispensary medical officer to hold the office of coroner; this was decided in the case of Dr. Carter, of Kilcullen. Dr. Hayes, of Naas, is a dispensary medical officer and coroner, but he held the latter office long before the decision in Dr. Carter's case.

VACANCIES.

Abbeyleix Union, Ballyroan Dispensary.—Medical Officer. Salary, £100, with fees, and £20 as Medical Officer of Health. Election, Sept. 26.

Alnwick Infirmary.—House Surgeon. Salary, £120, with furnished apartments, attendance, &c. Applications to the Hon. Sec. by Sept. 27.

Ardee Union, Collon Dispensary.—Medical Officer. Salary, £100, with fees, and £15 as Sanitary Officer. Election, Sept. 18.

Birmingham General Hospital.—Assistant Physician. Honorarium of £100 per annum. Applications to the House Governor before Sept. 29.

Brighton Lying-in Institution.—House Surgeon. Salary, £120. Applications to the Secretary, 76 West Street, Brighton, by Oct. 2.

Clifden Union, Clifden Dispensary (Innishboffin District).—Medical Officer. Salary, £90, with fees, and £10 as Medical Officer of Health. Election, Sept. 24.

Gloucester County Asylum.—Junior Assistant Medical Officer. Salary, £100, with board. Applications to the Committee before Sept. 22.

Newcastle-on-Tyne Infirmary.—Junior House Surgeon. Salary, £50, with board. Applications to the Secretary before Sept. 24.

Portumna Union, Portumna No. 1 Dispensary.—Medical Officer. Salary, £100, with fees, and £12 as Sanitary Officer. Election, Sept. 20.

Queen's College, Galway.—Professor of the Practice of Medicine. Applications, &c., to the Under Secretary, Dublin Castle

Shillelagh Union, Hacketstown Dispensary.—Medical Officer. Salary, £100, with fees, and £15 as Officer of Health. Election, Sept. 23.

Shillelagh Union, Coolattin and Clonegal Dispensaries.—Medical Officer. Salary, £100, with fees, and £15 as Sanitary Officer. Election, Sept. 19.

Sligo Union Workhouse.—Apothecary. Salary, £80. (See Advt.)

Tullamore Union, Clara Dispensary.—Medical Officer. Salary, £100, with fees, and £15 as Medical Officer of Health. Election, Sept. 24.

Victoria Hospital for Children, Chelsea.—Medical and Surgical Registrar. An honorarium of 50 guineas is attached to the office. Applications to the Secretary by Sept. 20.

West End Hospital for Paralysis.—Assistant Physician. Honorary. Applications to the Hon. Sec., 93 Welbeck Street, London, W.

Births.

Eascy.—On Sept. 9, at March, Cambridgeshire, the wife of William Easby, M.D., of a son.

Raverty.—On Sept. 3, at Boyle, the wife of J. R. Raverty, L.R.C.S.Ed., of a son.

Roth.—On Sept. 9, at Brighton, the wife of Bernard Roth, F.R.C.S., of a son.

Marriages.

Blackall—Ryan.—On Sept. 9, at St. Mary's Church, Dublin, John J Blackall, M.D., Kildysart, co. Clare, to Mary, daughter of John Ryan, M.D., of Ballinacally, Ennis, Dublin.

Craven—Lees.—On Sept. 16, the Rev. D. Craven, M.A., Incumbent of St. George the Martyr, Queen's Square, London, to Miss Florence Lees, Directoress of the Metropolitan Nursing Institute, Bloomsbury.

Davidson—Deane.—On Sept. 11, at Streatham, Chas. Davidson, M.D., of Coventry, to Ellen, daughter of the late Ed. Deane, of Fernleigh, Streatham.

Paget—Farr.—On Sept. 4, at Holy Trinity, Bromley, Henry M. Paget, to Henrietta, third daughter of Wm. Farr, M.D., F.R.S., D.C.L., of Bickley.

Shuttleworth—Hadwen.—On Sept. 10, at St. Paul's, Lancaster, G. E. Shuttleworth, M.D., Medical Superintendent of the Royal Albert Asylum, Lancaster, to Edith Mary, eldest daughter of Hy. Hadwen, of Ashfield, Lancaster.

Deaths.

Bennett.—On Sept. 3, at Leatherhead, Wm. Bennett, M.R.C.S., aged 70. For many years Medical Officer of St. Giles's and St. George's, Bloomsbury.

Dann.—On Aug. 4, on board *The Kashgar*, Surgeon-Major H. T. Dann, H.M. Bombay Army, aged 44.

Inglis.—On Sept. 6, at Beaumont, Jersey, Surgeon-General J. Gordon Inglis, M.D., C.B., Army Medical Department, aged 63.

Moore.—On Sept. 8, at Dungiven, Wm. Moore, M.R.C.S.E., aged 82.

Royston.—On Sept. 11, at Brighton, Melvenia, wife of Chas. Royston, M.D., of St. Stephen's Crescent, London, W., aged 49.

Stewart.—On Sept. 9, at Romanno House, Peebles, N.B, the elder twin son of Prof. Grainger Stewart, M.D., aged 7 days.

Wood.—On July 10, drowned the day of his arrival at Melbourne, Australia, Henry, eldest surviving son of Fredk. Wood, F.R.C.S., of Brighton, aged 25. Student of St. Bartholomew's.

Wright.—On Sept. 2, at Skipton-on-Stour, Martha Ann, widow of E. W. Wright, M.D.

IRISH POOR-LAW INTELLIGENCE.

LOCAL GOVERNMENT BOARD CIRCULARS.

THE NEW PUBLIC HEALTH ACT.

To the Clerk of Union.

SIR,—The Local Government Board for Ireland have reason to believe that some misapprehension exists as to the purport and effect of that part of their circular letter of the 15th inst., which relates to the salaries of the medical officers of health under the 11th section of the Public Health Act, 1878, and as to the information required to be given in the form of return which accompanied their letter of the 19th inst.

It appears to be supposed in some cases that the additional salaries to be determined by the sanitary authorities, and to be paid to the dispensary medical officers as "medical officers of health" under the 11th section of the Public Health Act, 1878, are to be in addition to the salaries hitherto paid to them under the 10th section of the Act of 1874 as "sanitary officers."

This, however, is not the case; the dispensary medical officers hold the office of sanitary officers, not by appointment of the sanitary authorities or of the Local Government Board; but they were so constituted directly by the Act of 1878. The effect of the repeal of that Act, and the simultaneous re-enactment under the Act of 1878 of the same provisions, with merely the change in the title of the officer from "sanitary officer" to "medical officer of health," is that now they hold their offices under the Act of 1878, and it consequently becomes necessary to consider the question of the salary, which under the 10th section of that Act is to be in place of, and not in addition to, the salary paid under the Act of 1874.

In filling up the return, therefore, which accompanied the Board's circular letter of the 19th inst., you should enter in the first column the salary paid to the medical officers of health as dispensary medical officers, in the second column the salaries hitherto paid to them as sanitary officers, and in the third column the salaries now proposed to be paid to them as medical officers of health in lieu of the salaries previously paid to them as sanitary officers.

By order of the Board,

B. BANKS, Secretary

Local Government Board, Dublin,
28th August, 1879.

THE NEW VACCINATION ACT.

SIR,—The Local Government Board for Ireland forward to you herewith for the information of the Board of Guardians, a copy of the Vaccination (Ireland's) Act, 1879, (42nd and 43rd Vic., cap. 70), which received the Royal assent on the 15th August last.

The Guardians will observe that the 3rd section of the Act requires that the child be taken for vaccination within three months after its birth, or as soon afterwards as may be practicable, instead of six months as heretofore; and that the 4th section requires that on the same day of the week following the day on which the child has been vaccinated, the child shall again be taken to the medical officer by whom the operation has been performed, in order that he may ascertain by inspection the result of the operation, and if he see fit, take from the child the lymph for the performance of other vaccinations. The 7th section enacts penalties for the violation or neglect of those requirements, viz., a penalty not exceeding 20s. for neglecting to take a child to be vaccinated or to be inspected after vaccination.

The 5th section requires that, immediately after the successful vaccination of any child, the medical officer or practitioner who shall have performed the operation, shall deliver to the father or mother of the child, or to the person having the care or custody of the child, a certificate of successful vaccination in the form prescribed; and shall also transmit a duplicate of the certificate to the registrar of births and deaths of the district within which the birth was registered. If, however, he is unable to be in such district, or if the birth of the child has not been registered, the duplicate is to be transmitted to the registrar of the district in which the operation has been performed.

The 8th section provides a penalty not exceeding 20s. for neglect to transmit any certificate, required to be so transmitted, or for refusing to deliver the duplicate to the parent or other person on request, or for refusing to fill up and sign the certificate of success for vaccination and the signing of a false certificate or duplicate is, by the same section declared to be a misdemeanour.

The guardians will also observe that in the 6th section of the Act, the medical officer is to be paid two shillings instead of one shilling, as heretofore, for every person successfully vaccinated, or re-vaccinated by him within his Dispensary District provided he has made the required report to the committee of management.

The 10th section authorises the guardians to direct proceedings to be instituted for the purpose of enforcing obedience to the provisions of the Vaccination Acts, and provides that the medical officer of any dispensary district, who may be required by the guardians to attend such proceedings shall be entitled to receive an addition to his actual expenses, such sum not exceeding one guinea, for such day's attendance required and given, as the court shall certify; these expenses, and all other expenses incurred in the prosecution, which the court is of opinion should be allowed are to be ascertained and certified by the justices or one of them, and are then payable out of the poor-rates of the Union.

By order of the Board,

B. BANKS, Secretary.

Local Government Board,
5th September, 1879.

CLAREMORRIS UNION.

LEAVE OF ABSENCE.

THE Clerk said that the Ballindine Dispensary Committee recommended three weeks' leave of absence to Dr. Kelly, and the board sanctioned it on last board day.

Mr. O'Connor—Who is to pay for the substitute?

Clerk—The dispensary district of Ballindine.

Mr. Treston thought that notice of motion should have been given.

Mr. O'Connor gave the following notice of motion :—

"I hereby give notice that I will move, on this day fortnight, that Dr. Robert Kelly be required to pay for a substitute during his leave of absence, which was granted on last board day."

SLIGO DISPENSARY.

THE PAYMENT OF TEMPORARY MEDICAL OFFICER.

DR. MURRAY wrote, asking to be paid nine guineas for acting as locum tenens for Dr. Palmer for one month.

Mr. Walsh—Dr. Palmer only got four weeks leave of absence. We cannot pay for the half week he is claiming.

Mr. Rowlett—We cannot go outside our former resolution, which was to pay two guineas per week for four weeks.

Mr. Walsh—And that will be £8 8s., not £9 9s.

The Chairman passed the account for £8 8s.

MEDICINES.

The Hon. Sec. laid before the Chairman a requisition for certain medicines and medical appliances.

The Chairman observed that the place where the medical officer should sign was a blank.

Mr. Phibbs—I think that in future all such requisites should be signed by our medical officers and apothecary before they are sent in.

The Chairman concurred with Mr. Phibbs, and he would be glad to receive a resolution directing this should be done in future.

Dr. Nixon—The medical officers always sign the requisition along with myself.

Hon. Secretary—There is a resolution on the books, calling on the medical officers to sign all such requisitions.

Mr. Walsh believed such resolutions only referred to accounts for medicines sent in, because that a long standing account was sent in from Dr. Donning for medicines supplied for a term extending over a year-and-a-half. It came before the meeting, and no one could tell how it was got.

The Chairman looked over the minute book, and found that the following resolution was passed on the 19th of June, 1879 :—

"Resolved—That in future any medicine required for the use of the dispensary be signed by Dr. Laird and Dr. Palmer, and the committee will decline to pass any bills unless this matter is strictly adhered to ; and that a list of all medicines in stock be furnished to the committee, and any medicine required for the ensuing month be applied for ; and that any medicine which may be received that the bill or invoice thereof be furnished to the secretary of the committee at their next meeting."

The Secretary having stated that he would get Dr. Palmer's signature to the document,

The Chairman signed it.

LOCAL GOVERNMENT BOARD INQUIRY.

W. ARMSTRONG, ESQ., L.G.B. Inspector, opened an inquiry at the Board room of the Sligo Workhouse, respecting a charge against Dr. Palmer of neglecting to attend a patient, named Thomas Gorevan, deceased, on a red ticket ; and also a similar charge against Dr. Palmer for not attending on one Martin Hurgadon, on a ticket.

Gorevan died on the 21st May last, without having any medical attendance.

The following guardians were present—

Alderman Magill, P.L.G. and hon. sec. of the Dispensary Committee ; Messrs. J. Walsh, F. Higgins, John F. Walker, G. W. Martin, and Simon Cullen. The Rev. Mr. Somers, C.C., and the Rev. Mr. Coyle, C.C., also attended.

Dr. Palmer was defended by Mr. Fenton, solicitor. Mr. M'Dermott, solicitor, came specially from Boyle to conduct the inquiry on the part of the friends of the deceased.

The first witness examined was Annie Gorevan, aged about 12 years, the daughter of the deceased, who stated that her mother sent her to Dr. Palmer's house with a red ticket to attend her father, who was then ill, and died on the following day.

Annie Gorevan deposed that she was the wife of the deceased Thomas Gorevan, and mother of the last witness. She remembered sending the last witness to Dr. Palmer with a red ticket to attend on her husband, who was dangerously ill, about the hour of 11 o'clock a.m., on the 21st May. Dr. Palmer not having attended, she sent again to him about one o'clock p.m., and again at four o'clock a.m. despatched a girl, named Brennan, and desired her to demand back the ticket. She having done so, Dr. Palmer's servant said she had handed the ticket to Dr. Palmer, but that he was then out on duty. Witness and Margaret Brennan went at nine o'clock p.m. and saw Dr. Palmer, who opened the door. Brennan asked him why he did not attend on the ticket. He replied that he would attend when he would think fit. Witness said, "All right ; remember your answer." He never came afterwards. It would not take more than a quarter of an hour to walk from Dr. Palmer's to witness's house.

By Mr. M'Dermott—Now, Mrs. Gorevan, it has been insinuated that you frequently beat your husband before his death, and that you are in the habit of being drunk.

The witness positively swore there was no truth in the statement.

Cross-examined by Mr. W. Fenton—I heard his life was insured for a small sum about four years ago ; he was aged about 40 years. It was myself registered his death at Mr. Dixon's. I did not drink any strong drink within twelve hours previous to his death. I never had a row with my husband in my life. I know a Mrs. Corcoran. She lodged at my house for a short time. She was not there for two or three days previous to my husband's death. I put her out for not paying the rent. I did not beat my husband on the night of his death, nor did he call out "murder." He was attending on Dr. Devany some two years ago at the dispensary. He was then ailing.

This closed the case for the complainants.

Ellen M'Andrew, Dr. Palmer's servant, was examined. She deposed—I recollect having received a red ticket for Dr. Palmer to attend Thomas Gorevan. The ticket was left about ten p.m. on the day in question by a child. She did not call again on that day to my knowledge. I generally attend the door as a rule. Some of the other servants did attend the door that day also. Two women came about 8·30 or 9 p.m. They "raised a noise." I did not see them ; I only heard them. I think it was the manservant opened the door for them. They appeared to be noisy. It was after two o'clock p.m. that day when I handed the ticket to Dr. Palmer. He went out on duty, and did not return to dinner until eight o'clock.

To Mr. M'Dermott—I don't take a note of all the red tickets left for Dr. Palmer. I got no other on that day. I think he went out after dinner, but I am not sure. It was not Dr. Palmer who opened the door when the two women came. I was in the pantry at the end of the hall, and heard Dr. Palmer from the dining-room door ask what noise was that?

Thomas Leonard deposed that he is a car-driver, and a member of the Royal Sligo Artillery. He lived opposite to Mrs. Gorevan in Pound Street. He knew her and her deceased husband well. He was frequently in the house.

Digitized by Google

She was in the habit of being drunk. He saw her repeatedly beat her husband before his death. He was always a delicate man. On the night before his death Mrs. Gorevan and a girl named Brennan had a row in deceased's house.

To Mr. M'Dermott—I did not hear there was a red ticket sent to Dr. Palmer to attend the deceased.

Bridget Leonard, wife of last witness, deposed that she knew the deceased and his wife well. She often saw Mrs. Gorevan drunk, and sometimes saw her beat her husband. About a month or so before his death she beat him.

Bridget Corcoran deposed that she lived a short time in the house of the deceased. She heard him cry out one night "Murder," and called witness to come and save him. On going into the room she saw Mrs. Gorevan with a chair and a candle in her hands. She flung the chair at her for attempting to interfere. That was on the 17th May, a few days before his death.

William Dalrymple, assistant in the late Dr. Nixon's shop, who acted as deputy-registrar of deaths for Dr. Palmer, said he entered death of Thomas Gorevan in the registy, at the instance of a person named Anne Gorevan, who represented herself to be the wife of the deceased. She stated that his age was forty-seven years, and that he had had no medical attendance for a month previous to his death. He recollected Dr. Palmer coming to Dr. Nixon's and leaving a red ticket, requesting Dr. Nixon to see after the matter. That was on the morning of the 22nd of May, about 10.30 a.m. He requested Dr. Nixon to inquire into the matter, as he (Dr. Palmer) had heard that the man Gorevan, whom the ticket was for, had died.

The inquiry was then adjourned.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF AUGUST, 1879.

August 1st.—Blair, Wm. Park; Ballynure, co. Antrim; Lic. Fac. Phys. Surg. Glas. 1879, Lic. R. Coll. Phys. Edin. 1879.

1st.—Magee, Wm. Joseph; 7 Rathmines Terrace, co. Dublin; Lic. R. Coll. Surg. Irel. 1878.

6th.—Macneece, Thomas Frederick; Clonfeacle Rectory, Moy, co. Tyrone; Lic. R. Coll. Phys. Edin. 1879, Lic. R. Coll. Surg. Edin. 1879.

7th.—MacKinlay, John; Mosside, Ballymoney, co. Antrim; M.D. 1878 and M.Ch. 1879 Q. Univ. Irel.

7th.—Shipsey, Jacob Thomas; Dunmanway, Co. Cork; M.D. 1879 and M.Ch. 1879 Q. Univ. Irel.

8th.—Haines, Humphrey; 1 South Terrace, Cork; Lic. R. Coll. Phys. Edin. 1879, Lic. R. Coll. Surg. Edin. 1879.

9th.—Smyth, James Camac; Royal Hospital, Belfast; Lic. R. Coll. Phys. Edin. 1879, Lic. R. Coll. Surg. Edin. 1879.

12th.—Darling, John Singleton; Ballina, co. Mayo; M.B. Univ. Dub. 1879, Lic. Mid. K. Q. Coll. Phys. Irel. 1879.

14th.—Quinlan, Denis; Glanworth Mills, Mallow, co. Cork; Lic. R. Coll. Phys. Edin. 1879, Lic. R. Coll. Surg. Edin. 1879.

15th.—Bricknell, Edmund Seymour; East Beach, Queenstown, co. Cork; Lic. R. Coll. Phys. Edin. 1879; Lic. R. Coll. Surg. Edin. 1879.

18th.—Macartney, Wm. Henry Christopher; 1 Wesley Place, South Circular Road, Dublin; Lic. R. Coll. Surg. Irel. 1879.

18th.—Poirotte, Benjamin; 12 Suffolk Street, Dublin; Lic. R. Coll. Surg. Irel. 1878, Lic. 1879 and Lic. Mid. 1879 K. Q. Coll. Phys. Irel.

19th.—Mitchell, Adam; Parsonstown, King's County; Lic. R. Coll. Surg. Irel. 1879.

23rd.—Hudson, Harry Chalmers; 73 Pembroke Road, Dublin; Lic. R. Coll. Surg. Irel. 1879.

23rd.—Shakleton, Edmund; 40 N. Great George's Street, Dublin; Lic. 1879 and Lic. Mid. 1879 K. Q. Coll. Phys. Irel. Lic. R. Coll. Surg. Irel. 1879.

23rd.—Rogers, Geo. Pigott; 4 Oxford Road, Rathmines, co. Dublin; Lic. R. Coll. Surg. Irel. 1879.

26th.—Harris, James Crofts; 33 South Terrace, Cork; Lic. R. Coll. Phys. Edin. 1879, Lic. R. Coll. Surg. Edin. 1879.

28th.—Cornwall, Wm. Cotton; Thomasfort, Ballygar, co. Galway; Lic. R. Coll. Phys. Edin. 1879, Lic. R. Coll. Surg. Edin. 1879.

28th.—Denning, Francis Arthur; 22 Knox's Street, Sligo; Lic. R. Coll. Surg. Irel. 1878.

Memorandum.

The following name has been erased from the Register of the Branch Medical Council, Ireland, during the month of August, 1879, pursuant to 14th sec. of the Medical Act, no reply having been received to several letters of application, viz.:—

Donellan, William; Tuam, co. Galway.

ABSTRACT OF REPORT ON THE DISTRICT, CRIMINAL, AND PRIVATE LUNATIC ASYLUMS IN IRELAND

(*Continued.*)

While on the subject of expenditure, we would again observe that in some asylums a scale of wages exists, not adequate to secure the employment of suitable attendants in the first instance, or their subsequent continuance, inasmuch as after having acquired experience, they not infrequently leave for better payment elsewhere. It is an unsuccessful sort of economy not to requite officers and servants in district asylums in a liberal manner, taking their responsibilities into account, and the nature of their avocations, but particularly after a long and faithful employment.

As the statute is administered it certainly cannot be agreeable to the Lord Lieutenant or the Privy Council to have applications incessantly submitted to them for orders to authorise an increase of a few pounds, mayhap, a few shillings, to the wages of an artisan or a subordinate attendant. It might be well, therefore, as already proposed by us, if a discretionary power were delegated to Boards of Governors by the Lord Lieutenant in Council, under whom, by statute, the fiscal control and management of district asylums are solely placed, reserving to the inspectors, if deemed just, an authority to fiat such increases for the satisfaction of the auditors; there, however, being a distinct limit beyond which they should not be allowed to extend without a specific Order in Council.

The working of public institutions for the insane in this country in 1878, has, as hitherto, been highly satisfactory, their various resident medical superintendents devoting every care to the well-being of the inmates, both in a domestic and professional point of view, in which latter they have been warmly supported by the visiting physicians. The general staff, including matrons, clerks, storekeepers, as well as subordinate officials and attendants, are, as a body, deserving of much credit. In fact, during the twelve months just expired, no serious causes of complaint, involving cruelty or criminal neglect of patients, have arisen.

We find, as so frequently noted heretofore by us, that the regular visitation of chaplains continues to be productive of much benefit, not only to inmates, who are capable of appreciating religious observances, but as exercising a wholesome influence over those in charge of them.

From year to year increased means of amusement are devised for the patients, who last summer at various asylums were permitted to enjoy excursions under the care of watchful attendants.

The frequent recurrence of reports to Parliament, once annually on the state of a department limited in its extent, though important alike in a public and individual aspect, cannot afford much of novelty or of interest in detail, for in truth, no sooner almost are returns obtained in one year from local institutions, than like forms are transmitted to be filled up, for the succeeding.

For example, if the number of epileptics, idiots, and imbeciles, resident in the 29 workhouses of Connaught

Digitized by Google

were contrasted as regards the two years 1877 and 1878, there would not appear from the complicated tables and printed returns before us, a difference of more than nine individuals in the two years. Similarly in Munster, with its 51 poorhouses, there is only a variation of 11 in the same periods; while as regards the mentally affected of all ages and types in Poor-law Unions in 1878, forming an aggregate of 3,337, twelve pages devoted to statistical figures do not expose a difference beyond one per cent. on the preceding year.

In no branch of the public service is this circumstance more observable than in the lunacy, and, perhaps, with less practical results, inasmuch as the responsible head of each asylum district affords annually to the residents in a detailed account of all matters, monetary and personal, of interest to the ratepayers. The enunciation of this doctrine may appear as pointing to a subterfuge from trouble, but it is not so intended, and the more particularly as the executive is at all times kept thoroughly cognisant by the inspectors of the working of district asylums.

If in their office an annual record system were established, it appears to us that more comprehensive and practical deductions could be obtained, by taking the relative statistics of a series of years, and contrasting them with each other, than as at present by publishing details from twelvemonth to twelvemonth, which are fluctuating, and dependent in great measure on chance occurrences.

WORKHOUSES.

The total number of the mentally affected of all denominations, in workhouses, as obtained by us through the Local Government Board, was 3,335 at the 31st December, 1878, being 37 less than in 1877. 1,241 are represented as lunatics, 1,394 idiots, 702 epileptics.

It is gratifying to find on examining the returns for some years past, that if the idiotic element under fifteen years of age be computed in Ireland it amounts only to 88; if between 15 and 30, to 395; and if over 30, to 911; from which the inference may be naturally drawn that idiocy is on the decline in this country.

As a rule, the above-named classes occupy special apartments, known, in the primitive construction of workhouses as the idiots' cells.

We cordially recognise, from our frequent visits to these establishments, a general disposition on the part of boards of guardians throughout the kingdom to meet more liberally all just requirements, and to carry out our suggestions in behalf of the insane so far as the restricted capabilities of poorhouses permit. A material benefit would result were paid attendants employed, but bearing in view the fact that in some workhouses there may be but four or five, even less, mentally incapable to look after themselves, it would not be quite fair to the ratepayers to increase taxation in their regard by the employment of special warders to take charge of them in each union. The best solution of the difficulty might probably be found by allocating, wholly or partially, one or more workhouses in each district, according to its size, to the reception of harmless idiots, epileptics, and the utterly demented or fatuous, who are now diffused through no less than 163 unions, in most unequal proportions. Many years ago, and subsequent to the inquiries of a Special Committee of the House of Lords, the erection of four provincial hospitals for idiots, imbeciles, and a certain class of incurables was adverted to in a report to Parliament. In our opinion provincial depots would not prove to be so successful as might be wished; the number of counties attached to them, as for example, twelve in Leinster, would cause much embarrassment in their working, while unavoidable expenses and inconveniences consequent upon the conveyance and return of patients from remote localities, perhaps from 100 to 130 miles distant, must constitute very serious objections. It appears to us more feasible that lunatic districts should have each its own receptacle for chronic cases.

In regard to sex, two-thirds of the combined classes are females, aged, physically debilitated, and long resident. As a rule, too, the males are similarly circumstanced, both sexes giving but little trouble. Occasionally, however, if individuals become irritable or refractory, they are at once transferred as dangerous lunatics, too often, it must be confessed, under frivolous pretexts, to district asylums; and thus it occurs without the least actual benefit, in a curative point of view, to parties whose far advanced life and bodily weakness exclude the hope of recovery, that institutions erected for other objects become overcrowded, to the exclusion of curable cases, and of cases which, however unpromising, need special supervision.

CENTRAL CRIMINAL, OR DUNDRUM ASYLUM.

With reference to the central asylum at Dundrum for criminal lunatics, now in its thirtieth year of operation, having, from the beginning, had its unlimited management, we feel justified in reporting that it continues to progress in the same satisfactory manner we have hitherto noticed. Originally constructed for 80 males and 40 females—there being at the date of its opening 186 individuals criminally insane in district asylums or in gaols—a necessity was entailed on the inspectors to select from out that number those only whose crimes were of such a serious nature, or whose propensities were so vicious, though charged only with misdemeanours, as to render them particular objects for detention in a State institution. To have placed lunatics in it, well conducted, and accused simply of petty offences, though thereby actually coming within the category of criminal, appeared to us uncalled for.

In 1864, owing to a progressive overcrowding, the accommodation of the asylum was enlarged by 50 beds at the male side, that at the female remaining unchanged. Gradually, since then, the number of patients has been increasing—so much so that on the 31st of December last year there were resident in the establishment 177—140 men and 37 women. At no period, however, has there been an excess of the latter sex beyond the primitive complement. Two peculiar circumstances have tended to the repletion of the Dundrum more rapidly than to that of an ordinary district asylum—1st, the mortality in it has not exceeded 3¼ per cent. in the year on the average under treatment, as against 8 elsewhere; 2ndly, when a patient recovers, a discharge does not necessarily follow, and under no circumstances is an uncured lunatic let out on probation before the close of his legal imprisonment.

Within the past twelvemonth a larger number of criminals (23) was admitted than in any other year subsequent to its occupation—the great majority of them coming from convict prisons, and composed of persons who, prior to their conviction, had shown no symptoms of insanity. In fact, it has been latterly observable that offenders of every kind, when sent to gaol for a longer or shorter period, are particularly subject to delusions—possibly from being well skilled in the art of malingering. Some also become so pertinaciously troublesome as to interfere with prison discipline.

(To be continued.)

TO READERS.

The Editor will feel especially obliged by receiving copies of newspapers which contain any Poor-law or other intelligence of medical interest, in order that he may, if fit, republish it for the benefit of the readers of the *Medical Press*. Although twenty-one of the leading Irish newspapers are received at the Irish office, many things may escape notice which are deserving of attention. Newspapers should be marked, and addressed to Dr. Jacob, at the Dublin offices of this paper.

STUDENTS' NUMBER.

PART I.—The future of the Student in Private Practice or the Public Services.

PART II.—The Education and Qualification of the Student in the United Kingdom.

PREFATORY.

It is mortifying to have to record that another session will commence under the old unsatisfactory regulations by which the education of the medical practitioner is guided. Good hopes were entertained early in the year that the new Medical Acts Amendment Bill would, ere its close, be the law to which the various schools would be required to conform. And when matters had progressed to the appointment of a Parliamentary Select Committee, which should receive evidence concerning the Bill, yet brighter burned the hope that an end was at length to be put to the frightful anomalies that lend unenviable distinction to the medical profession. Vain and empty as the nothings so plentifully dealt in by many of the witnesses, the efforts of the Committee will in all probability be productive of nothing beyond the storm of criticism that has already been evoked through them; and until another Parliament sees fit to pass a much needed measure of medical reform, it seems most probable that the abuses and evils everywhere lending indignity and opprobrium to the name of physician and surgeon, must continue unabated, unrepressed.

Very much of the good that would result from the introduction of the "tri-portal" system is so self-evident, that the wonder is the measure enacting its introduction has not already become law. Unspeakably more of actual benefit, than of possible loss, must necessarily arise, not alone to the profession, but to the laity also, through it; and it is a matter of sheer amazement that any strenuous opposition should be urged against what embodies so considerable an amount of good. This opposition, too, is the more regretable since it comes from a quarter that should be foremost to champion the cause of progress. Indirectly, through their disinclination to welcome among them the "direct" representatives of the profession, the majority of the members of the General Medical Council practically condemns the Bill which embodies direct representation in its clauses; and thus, what might and could have been an immediate engine of advance, has been doomed to destruction, because of the stilted exclusiveness of a few fancy-hoarding representatives of unreasoning respectability.

In the Session 1879-80 there exist nineteen licensing corporations, empowered to grant certificates to practise medicine or surgery, or both; and diverse, as from their number, the standards of examination among them must be, this is less glaringly so than the similar diversity to be found in the "preliminary" knowledge exacted from candidates. It is satisfactory, however, to note that the appreciation of the importance of an acquaintance with the main laws of natural science, is increasingly apparent on the examining boards; and particularly must it be remembered that, at a recent sitting, the Medical Council directed that physics and mechanics be no longer quoted as "optional" subjects in the preliminary, but that every candidate thereat be *compelled* to exhibit an adequate acquaintance with their elementary principles.

In the line of more purely professional study, a marked prominence is being given to physiological work, and a rapidly growing feeling shows itself in favour of offering increased facilities to the student who seeks to render himself, by practice or by reading, a physiological expert. Still greater stimulus will be afforded to this movement by the decision of the English Royal College of Surgeons to separate the subjects of anatomy and physiology hitherto included in one single paper. Henceforth—commencing, that is, from January next—at the "primary" examination of the College of Surgeons, two papers will be set: one containing only physiological, the other only anatomical questions. The influence of this change from the old plan of a mixed paper will be quickly felt, and will be beneficial to the advance of medical education.

In the higher walks of the profession, an ever-extending spirit of research is manifest; and we can with pride point to many of the works produced during the past academic year, in proof of the assertion that we retain our foremost place in the ranks of the scientists. Much has been accomplished in this way, especially in sanitation, and the perfecting of the system of preventive medicine; but immeasurably more, it must be said, yet remains undone; and however great and earnest they be in intention or in act, the army of workers in the field of discovery in medicine, and improvements in surgery, will need continual fresh accessions, and continual strong recruits. It is to them, to the students of to-day, the practitioners of an immediate future, that we address ourselves in this number of the *Medical Press and Circular*.

We have, as is our wont, given in our present issue merely the pith of the official regulations of colleges and public services, reserving our space for practical advice and

Digitized by Google

information which every student needs, and leaving our readers to obtain for themselves the official regulations in a more reliable form than we can offer it. We conceive it to be our *rôle* to place in the hands of the student and his guardians the semi-confidential details, directions, and hints which college regulations are not intended to communicate, and which are only known to those conversant with the various systems of education, examination, and qualification, and with the ultimate prospects of the student.

PART I.

THE MILITARY AND NAVAL SERVICES.

THE chaotic state of the Army Medical Department which we last year spoke of as impending, has culminated since then in such a complete breakdown of the Queen's Medical Service that it is hardly worth while to devote space to the regulations of that service. No one, save a very few hard-up students, now thinks of presenting himself for the honour of Her Majesty's army surgeon's uniform, and the War Office has been obliged to abandon the competitive examinations announced for August last, because there was no competition, and only a few names of third-class men were sent in. A committee has sat within the past year to consider the reasons for the unpopularity of the service, and they have made recommendations, some of which are favourably regarded by the profession, and some altogether repudiated. It is understood that a new army medical warrant based on these recommendations, is ready, and that it only awaits the approval of the Treasury to be promulgated. But "My Lords" object to pay for doctors, and object to the warrant in this respect, and consequently the matter hangs fire. Meanwhile, our soldiers at Cabul and Cape Town are undergoing medical starvation, and are obliged to depend to a certain extent upon a number of civil medical practitioners who, failing to take root in practice at home, are glad to learn a little military surgery on the *corpus vile* of the British soldier.

The Indian *Medical* Service has grown into popularity upon the ashes of the British Army Medical Department, and an examination has recently been held at which there was a fair competition for places. The following are the regulations in abstract:—

1. Candidates must be between the ages of 22 and 28.
2. May be married or single.
3. Must be registered as a practitioner, and possess diplomas in both medicine and surgery.
4. Must send a fortnight before the examination to the Military Secretary, India Office, a declaration (according to printed form), that he labours under no mental or constitutional disease, nor any imperfection or disability that can interfere with the most efficient discharge of the duties of a medical officer in any climate. His physical fitness will be determined by a board of medical officers, who are required to certify that the candidate's vision is sufficiently good to enable him to perform any surgical operation without the aid of glasses. A moderate degree of myopia would not be considered a disqualification, provided it did not necessitate the use of glasses during the performance of operations, and that no organic disease of the eyes existed.
5. Must send with the declaration,

a. Proof of age, either by his own sworn declaration (on printed form), or by extract from parish register. Baptism certificate not sufficient unless it affords proof of age.

b. Certificate of moral character from a magistrate or clergyman of candidate's church who has known him for at least last two years.

c. Certificate of registration.

Having received his diploma in surgery and medicine, both of which are essential to his competition, the student is obliged to apply himself vigorously to the study of certain collateral subjects, which he does usually through the medium of a "grinder." He must perfect himself in chemistry, pathology, and comparative anatomy, and if he can throw a proficiency in botany and natural history, and French and German into the scale, he will materially improve his position in the scale of merit, and establish for himself a character with the authorities for industry and scientific attainments.

The examination usually takes place in February and August. The candidate will be examined in the following *compulsory* subjects: *a.* Anatomy and Physiology (highest marks attainable), 1,000. *b.* Surgery, 1,000. *c.* Medicine, including Therapeutics, the Diseases of Women and Children, 1,000. *d.* Chemistry and Pharmacy, and a Practical Knowledge of Drugs, 100. The examination in Medicine and Surgery will be in part practical, and will include operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside. The *eligibility* of each candidate will be determined by the examinations in these compulsory subjects only. *Optional Subjects.*—Candidates who desire it will be examined in French, German, and Hindustani, Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany, with special reference to Materia Medica; and the number of marks gained will be added to the marks in the obligatory part of the examination, and position on the list of successful competitors will thus be improved in proportion. The maximum marks allotted to the voluntary subjects will be as follows: French, German, and Hindustani (150 each), 450 marks; Natural Science, 300 marks. The subjects for this part of the examination will be taken from the following books: "Animal Kingdom," by W. S. Dallas, F.L.S. "Outlines of the Structure and Functions of the Animal Kingdom," by Rymer Jones, or "Cours Elèmentaire d'Histoire Naturelle," by Milne Edwards. Lindley's "School Botany," Lindley's "Medical and Economic Botany," Henfrey's "Elementary Course of Botany." "Elements of Natural Philosophy," by Golding Bird and C. Brooks. "Physical Geography," by Mrs. Somerville.

For the first two days of his examination the candidate is employed in penning answers to printed questions; for the third and fourth days he is examined *viva voce* on all subjects; and on the fifth and sixth days he is tested by the diagnosis of disease at the bedside in the hospital, by the application of surgical apparatus, and by operations on the dead subject.

PROBATION AT NETLEY HOSPITAL.

The competitor who obtains a place in the ordinary service is not allowed to join a regiment at once. He is obliged to undergo probation of four months at Netley Hospital, near Southampton, where he is compelled to attend the following lectures: Pathology, by Dr. Aitken; Military Surgery, by Dr. Longmore; and Clinical and Military Medicine, by Dr. Maclean; Military Hygiene, Dr. de Chaumont: and Dr. Macdonald, on Naval Hygiene. The lectures on Military Surgery include gun-shot and other wounds; duties of army surgeons in the field, during sieges, on transport, &c., and other special subjects. Those on Military Medicine refer to the tropical and other diseases of the British possessions and colonies, and to the losses by disease. The lectures on Hygiene relate to the examination of water, air, food, and clothing, &c., of the soldier, his duties and exercise, and the circumstances affecting his health, meteorology, statistics, and prevention of disease. The lectures on Pathology have reference chiefly to the scientific examination of tropical diseases, and of the other complaints which the army surgeon is especially called on to investigate. The candidates also attend the wards of the hospital under the Professor of Medicine and Surgery, to make themselves acquainted with the system of recruiting, and the modes of keeping the Army Medical Returns. They are also called on to make post-mortem examinations, to operate on the dead body, and to pass through laboratory practice on the modes of recognising the qualities and adulterations of food, and on microscopic examination of morbid tissues, and adulterations of food, &c. During his preliminary training here the student is understood to be in Her Majesty's Service; he wears uniform, is under military discipline, and receives pay at the rate of five shillings a day, and two shillings a day for lodging money, if he be not provided with lodgings in the hospital. A sum of money equal to the half-yearly interest on £1,200, the surplus from the "Herbert Memorial," is at the end of each session awarded to the candidate who has the highest number of marks, the fortunate young man who wins this "Blue Ribbon of Netley" being tolerably certain to be well provided for. At the termination of the four months he is again examined in the subjects in which he has been instructed during that period, his marks are added to those obtained by him at the competitive examination, *and his position on the list of merit determined by*

Digitized by Google

the total. Successful candidates are now eligible to be gazetted to a regiment, or employed on the staff, and enjoy all the rank and honour, pay and privileges, of surgeons, as provided by regulations.

Thus it will be observed that the first examination simply admits the candidate to the Service, and the conjoint result of it and the Netley examination determines his order of merit. Each candidate has to pay £5 towards the mess fund, one-half on his arrival and the remainder when he has passed his second examination. He is then a member of the mess, and entitled to dine at any time during the remainder of his service. The cost of dinner is 2s. 4d. daily, not including wine, and of breakfast from 10d. upwards.

PAY.

The rates of pay of the officers of the Army Medical Department are as follows:—Daily pay: Surgeon-General, £2 to £2 10s., according to length of service; Deputy Surgeon-General, £1 10s. to £1 17s.; Surgeon-Major, on appointment, £1, after five years' service as such £1 5s.; Surgeon, on appointment, £250 a year, after ten years' service 17s. 6d. daily.

* On the completion of ten years' service, unless the Surgeon be selected for further employment in the department, or, if he be unwilling to continue, his services are dispensed with, and he shall be entitled to receive 1,000*l.*

† If he have served five years on full pay, and be unable to resume duty, he shall be entitled to receive, if he shall have completed nine years' full-pay service, 800*l.*; eight, 700*l.*; seven, 600*l.*; six, 500*l.*; five, 400*l.*

Passage allowance to India on appointment will be given or a passage provided. When passages are provided on board the Indian troop-ships, a charge for messing will be made at the rate laid down in the Royal Passage Warrant of 1865. Pay at 10s. a day will be allowed from date of passing final examination at Army Medical School.

Indian allowance and time of service for pension will reckon from the date of arrival in India.

Surgical instruments are provided in India by the Government for the use of medical officers.

The pay of medical officers in the Indian service is much better than at home, and, if unmarried, the cost of living not greater. Moreover, the medical officer frequently holds lucrative civil medical appointments which afford him a handsome increase of income. Without doubt, to a healthy, temperate, unmarried man, the Indian Service is greatly preferable to that at home, but to a delicate person, or one burthened with a wife and children, the advantages are questionable.

For official regulations of the Indian Medical Service apply to the India Office, Whitehall, London, S.W.

SERVICE ON THE WEST COAST OF AFRICA.

A certain number of candidates, whose answering has been satisfactory, but not sufficiently so to entitle them to a place, were formerly offered appointments on the West Coast of Africa, but recently they have been appointed to the Naval Medical Service, as vacancies on the Coast have not existed for some time. These situations, while they are subject to strong objection on the score of the deleterious nature of the climate, possess some advantages for those whose health can resist its influence. The districts comprised under the West Coast Districts are Sierra Leone, Gambia, and Cape Coast Castle. If the candidate accepts the appointment he is sent out at once, without the period of probation to which others are subjected at Netley Hospital. He is allowed to spend a year at home on full pay, for every year spent in Africa, and the entire period at home and abroad should count as service for pension.

NAVAL MEDICAL SERVICE.

This Service still maintains its position, for though there is much dissatisfaction on the part of many of its officers, there is an adequate supply of candidates for admission to its ranks. The arrangements, time, and places for examination, the declaration to be made, and documents produced, the subjects and method of examination, and the subsequent probation at Netley are to all intents exactly the same as those quoted above for the Indian Medical Service.

Having passed his examination and served at Netley, the candidate will, in the course of the following day, receive his appointment as acting Surgeon to one of Her Majesty's ships, either for service on board that ship, or for service on shore, at one of the naval hospitals—Haslar or Plymouth. He will at the same time be informed that he is granted two or three weeks', as he may require, leave of absence, to enable him to provide his uniform and appointments. These he can get at any of the naval clothiers.

The expense of a Surgeon's uniform is about 47*l.* 5s. The candidate must also provide himself with a set of surgical instruments, which will cost him from ten to fifteen guineas. All kinds of underclothing, towels, handkerchiefs, &c., may be purchased much more advantageously from a regular dealer in those things than from the naval outfitter.

Surgeons, on entry, have the same rank as Paymasters, Chief Engineers, and Naval Instructors—namely, to rank with Lieutenants under eight years' seniority.

Fleet Surgeons to have the option of retiring after twenty years' full-pay service in all ranks at 15s. per day, and after twenty-five years, 21s.

Medical officers share in the proceeds of all *prizes.*

The full and half-pay of Naval Medical Officers is in accordance with the following scale:—

Full-pay: Surgeon—From 11s. (under five years' service) to 17s. a day, above fourteen years' service. Staff-Surgeon—On promotion, or under fourteen years' service, 18s., up to 22s. a day. Fleet-Surgeon—On promotion, or under twenty years' service, 1*l.* 3s. up to 30s. a day. Deputy Inspector-General of Hospitals and Fleets—On promotion, or under twenty-two years' service, 1*l.* 11s. up to 38s. a day. Half-pay: Surgeon—Under five years' service, 6s., and up to 17s. a day after eleven years. Staff-Surgeon—On promotion, or under fourteen years' service, 11s. up to 15s. a day. Fleet-Surgeon—On promotion, or under twenty years' service, 16s.; until the maximum is reached—namely, 18s. 6d.

THE CIVIL PUBLIC SERVICES.

POOR-LAW MEDICAL SERVICE.

A YOUNG qualified practitioner, indisposed to be an assistant, and desirous of commencing general practice without investing any money in purchasing a succession, may, perhaps, obtain a Poor-law appointment, though he should scarcely expect to obtain a livelihood from the inadequately remunerated appointment.

ENGLISH POOR-LAW MEDICAL SERVICE.

The English Poor-law Service differs in many respects from the Irish. Each parish in England and Wales has its guardians of the poor, and these parishes are grouped together to form unions. The unions are divided into districts for medical relief. Union medical officers therefore have the care of a district, and sometimes of a workhouse as well; sometimes only a workhouse. He is elected by the guardians of the union, and the appointment confirmed by the Local Government Board. He must have both a surgical and medical qualification, and be registered, and is required to name a duly-registered practitioner to whom application can be made in case of his absence from home; he can name his assistant or partner as his substitute. As a general rule, the guardians may not assign to any medical officer a district which exceeds in extent the area of 1,500 acres, or which contains a population exceeding 1,500 persons. This does not apply to Wales, but no such district may be assigned to a medical officer residing more than seven miles from any part of a parish included in such district. A medical officer is entitled to a fee of not less than 10s. or more than 20s. for attending a woman in or immediately after childbirth, and to a fee of £2 where great difficulty has occurred in delivery, or long subsequent attendance has been necessary. Many of the salaries of Poor-law appointments are very low—often so out of proportion to the work done that the medical officer must give his services for nothing, or next to nothing, as he has to provide all medicines, instruments, &c., except trusses, cod-liver oil, and quinine, for which he sends a statement to the guardians, who pay him the cost price; the paupers have to put up with those medicines which cost the least. In London and large towns some boards of guardians provide dispensaries, where the paupers are supplied with medicine, which relieves the medical officer from much labour and expense. It ought to be compulsory on all boards of guardians to provide dispensaries, and where this

Digitized by Google

cannot be done, as in country districts, to provide all drugs, &c.

Capital operations, dislocations, fractures, midwifery, and vaccinations are paid for by a fixed tariff. The public vaccinator is appointed by the guardians. He may not be connected in any way with the parish work; the candidate who has most interest is pretty sure of the appointment. The fees for vaccination are 1s. 6d. if performed at a workhouse or within a mile of the vaccinator's residence, 2s. between one and two miles, and 3s. over two miles. The guardians provide stations for vaccination where the vaccinator attends at stated times. He must be registered in medicine and surgery, and have obtained a certificate of instruction in vaccination, from a public vaccinator, authorised by the Privy Council; he is required to transmit the certificates of successful vaccination to the vaccinating officer within seven days. Awards of not more than 1s. per case are given for successful vaccination of children up to six months, and are given on the report of the inspector to the Local Government Board if the marks are up to the standard, and the books properly kept. Only the relieving officers (and the overseers of the several parishes in cases of emergency) can give orders for medical relief. The relieving officer must inquire into the case, and, if necessary, visit the person before giving an order, unless the person is already on the pauper list. The medical officer can order nourishment and stimulants when necessary.

In England and Wales (more especially in the manufacturing districts) the medical practitioner derives much of his income from clubs, which pay him from 3s. to 4s. per head yearly, for which he visits and supplies medicines, performs operations, &c.; the average payment for each visit amounts to the large sum of about 6d. Small tradesmen, artisans, tenant farmers, labourers, &c., who would certainly be recipients of gratuitous relief in Ireland, are attended as private patients—of course, at lower charges than the better class of patients, and often either pay their bills by instalments or not at all. Parish appointments are often sought for by young men as an introduction to practice, or by older men to prevent opponents setting up in the district.

THE IRISH POOR-LAW SERVICE.

The newly qualified medical practitioner who may elect to try his luck in the Irish provinces sets his hopes, in the great majority of instances, upon obtaining one or more Poor-law medical appointments in some district where there is hope of private practice. There are 163 workhouses and about 793 dispensary medical officers, besides apothecaries. The number of vacancies that occur annually averages 100. The salary in this service averages about £103 15s.; and when it is taken into consideration that in the vast majority of rural districts, it is necessary to keep a horse, and in some a boat as well, the average area being from forty to sixty square miles, it is plain that there will not be a very large margin left from the public emoluments. The medical officer is also *ipso facto* the registrar of births, marriages, and deaths, and the medical officer of health for the district, under the Public Health Act passed in 1873 and amended in 1878.

The former office, in country districts, seldom yields more than £10 a year, and often not half that amount, and the emoluments of the latter appointment in very few cases reach £20 averaging about £12. The medical officer is also vaccinator for the locality, and is required to vaccinate everyone who wishes to come. For each patient his fee of 1s. (which has been raised to 2s. by the Vaccination Act of last Session), is paid, along with his salary, by the guardians, and the sum total of these fees varies, according to the populousness of the district, from £2 to £50, an average for the provinces, under the old system, being about £5. Despite the miserable salary, and the very many discomforts of dispensary life, these appointments are generally eagerly sought for—firstly, because they afford the new comer a certain, though hardly-earned salary, to supplement his private earnings; and, secondly, because, if not secured by the new comer, they would of necessity bring a competitor for practice into the field, and inasmuch as private income is of far greater import than public earnings, country medical practitioners are obliged to undertake the public duty in order to save themselves the monopoly of their private emoluments.

APPOINTMENT.

The qualifications required by the Poor-law Commissioners are a Licence in Surgery or a Diploma in Medicine, and a Diploma in Midwifery; the candidate must also be 23 years of age.

The appointment lies with the Dispensary Committee, who elect by vote. As politics and religious feeling run high in Ireland, these elements enter into the election of Poor-law medical officers. Family interest also possesses great weight.

The candidate will do well to bear these facts in mind, as his personal attendance on the day of election will be required, and whatever other qualification he may have, he will then find that his compatibility in these respects with the majority of the committee is essential; and, accordingly, he had better first make himself acquainted with the local peculiarity, whatever it may be, before he enters on his candidature, otherwise, in all probability, any expenditure that he may make in the matter will be simply thrown away. We may here observe, also, that in very many instances the appointment is virtually made before the advertisement appears for a medical officer, in which case, also, candidates are put to unnecessary trouble and expense under false pretences.

CONTROL.

Each district is under the direct control of a committee composed of the neighbouring landholders; the appointment of medical and other officers is made by this committee, and the entire management of the district is under their control. Their acts are, however, subject to the approval of the Local Government Board, who have the power either of interposing their veto on any appointment, or even expelling an officer by a "sealed order," without trial or accusation, or without the resource of appeal or investigation. The salary is paid by the Board of Guardians, and no increase can be made in the amount without their assent and that of the Local Government Board. Under the late Sanitary Act the committee may recompense the medical officer for special services, such as those during an epidemic of cholera, or for sanitary reports. The number of unions in Ireland is 163, to each of which is attached a medical officer, who is appointed and controlled by the Board of Guardians in the same manner as the dispensary surgeon is by his committee. The salary is usually better than that of the dispensary doctor, and the duties of a more easy and satisfactory description, inasmuch as the duties are confined to daily attendance at the workhouse hospital, and no night visits out of doors or any long journeys across the country are involved.

DUTIES,

The duty of the dispensary doctor is twofold. He is to attend his dispensary on a given day or days in the week. Frequently there are two dispensaries in the district, separated from each other by several miles, and he will have perhaps to attend two days a week. He has also to visit at any hour of the day or night a sick person for whose relief a visiting-ticket has been issued by a member of the committee or the relieving officer, and to continue his attendance as often as may be necessary until the termination of the same. Moreover, he has a great many registry books to keep and a multitude of returns to make, and in the majority of districts he has to make up all the medicines for the poor.

The pressure of these duties is in the greatest degree dependant on the goodwill of the members of his committee. If the medical man be a favourite with his masters, they will give him very little trouble with "scarlet runners," as the visiting tickets are, from the colour of the

Digitized by Google

paper on which they are printed, humorously called, and will be unwilling to trouble him even with cases deserving of personal attendance.

If, on the other hand, it is his misfortune to come in contact with some of the half-bred committee-men, who know nothing of the treatment fit for an educated gentleman, or cherish a personal spite, the discharge of his duties may become simply unbearable. He may be peremptorily summoned, in any weather, at any hour, and to any distance to a case which he may probably find to be altogether trivial, or to a person whom he may know to be perfectly well able to pay—aye, even to the committee-man's own brother or daughter.

SUPERANNUATION.

A Poor-law medical officer may now receive a pension not exceeding two-thirds of his salary on being incapacitated from illness or old age. This grant is strictly at the discretion of the guardians; nevertheless, it has been given in most cases in which physical incapacity has been clearly proved. It is, however, at best a miserable resource, and can by no means be calculated upon as a provision for old age. There are now nearly 60 ex-medical officers receiving superannuation allowance, whose average term of service before pension was 20 years, and whose average allowance is £64 15s. Their average at retirement was 63. All official information may be obtained of B. Banks, Esq., Local Government Board, Custom House, Dublin.

Complete information as to fees, emoluments, duties, and appointment of Irish Poor-law medical officers will be found in the "Irish Medical Directory" for 1879.

ASSISTANCIES, &c.

Many men, looking over the voluminous accounts of college curricula and university regulations, either for themselves or their sons, may naturally draw a deep sigh over the work to be done or the money to be spent, and exclaim, "What then?"—or, to quote Mr. Cobden's familiar expression, "What next, and next?"

Of course the full and complete reply to these questions would fill a volume or two; but we may briefly indicate what can and what cannot be done, *as a rule*. (*a*) There are many exceptions, but we advise no one to think that he will escape the general rules which affect the mass of men.

First, there is private practice as a destiny and ultimatum. In Ireland and Scotland it is generally found that private practice worth having only exists in large towns; elsewhere, in those parts of Great Britain, medical men live chiefly on their appointments. In England this is not so; the appointments are subordinate to the practice everywhere. In England the succession to a practice can be very generally secured by purchase; but this is not so in Scotland or Ireland. But in England there are practices which cannot be bought; no money will command the highest class of practice, which is a personal thing which attaches to a man, and cannot be transferred. Partnerships are regarded as safe introductions to practice, but apart from the notorious changes of partnerships, we regard them as greatly over-estimated in value. In considering a sphere for practice, the first question is the adaptability of the purchaser to what he contemplates. An Irish Catholic will fail to secure a practice in an English country town, and a bigotted Low Church Englishman will fail in an Irish Catholic district. The best parts of London, Brighton, Eastbourne, Bournemouth, and fashionable places like Scarborough, Harrowgate, &c., are the rocks and syrens of medical practice. A suitable man will, as a rule, succeed to any practice where he is favourably and systematically introduced to the patients by his predecessors; but no man will undertake to resign his appointments and introduce a successor without a *quid pro quo*. Unless, therefore, a man has capital, he should not think of purchasing a practice.

A prevalent fallacy is that some man overworked wants a partner to relieve him of part of his work and—his income. If the practice is fairly good, the overworked gentleman can readily find a partner who will pay two years' purchase for the share secured. But some one wants to join him as a "working partner," and to pay nothing. Which is the overworked gentleman likely to accept—a junior partner, who will pay perhaps £1,000 for his share, and to whom he can delegate the greater part and all the drudgery of his work, or the junior who will do the same work, but will not pay the £1,000?

An assistantship is a capital discipline for any man. Such engagements are not what they used to be; the assistant in a medical practice being treated as a gentleman. But for details on this head we would refer to Langley's "Via Medica," which deals fully and fairly with this subject. No man should go out as an assistant without reading it, and especially as it is to be found in nearly every college library.

Medical assistants may be divided into two classes, qualified and unqualified; but the salary which either will obtain is far more a question of actual experience than of the diploma which may be held in any given instance. The experience obtained by an assistant in England, even though unqualified, may be sufficient to enable him to obtain a far higher salary than many gentlemen of much higher qualifications, but without knowledge of English practice.

To act as "Locum Tenens," it is essential that previous experience of practice should have been obtained. Irish gentlemen, as a rule, are very deficient in dispensing, and the routine of English practice, which differs very materially from that which prevails in the sister isle, and to this cause may in many cases be attributed the expression oftimes seen, "No Irish need apply."

An assistantship, "with a view to partnership," is a thing that people read and write of, but seldom see. Experience shows it to be a mistake on both sides. If the assistant has money, he had better not appear in the practice as subordinate; if he has not, the probation will not assist him to get a share in the practice.

If, however, a successful student declines to enter private practice as purchaser or as assistant, he may enter the public services through the open doors of competitive examinations.

Practices abroad are rarely to be had or heard of. Sometimes they can be secured upon equitable terms; the contracts, however, should be always conditional upon the practice "out there" being found what it is represented to be. In such cases the intending purchaser should avail himself of the skill of some experienced and respectable medical agent.

In conclusion, it may be stated that whilst we have indicated generally the portals to success *after* the diploma has been obtained, we have no intention of ignoring the fact that men of decision of character, good antecedents and high qualifications, can and do secure distinguished positions in the profession, and occupy a large space in the eye of the world. But genius is the heritage of the few, and the great majority of men will do well to moderate their ambition, and seek to do their duty in the customary spheres of life in which many noble-hearted men have lived and worked and died, leaving the world somewhat better than they found it.

(*a*) For further information we would refer the reader to Langley's pamphlet, "Advice on the Transfer of Medical Practices, &c."

PART II.

EDUCATION AND QUALIFICATION OF THE STUDENT.

The parent who desires to make a doctor of his son, or the student who selects that profession for himself, is probably already aware in a broad way of the steps which must be taken to effect this purpose. He knows that in order to practise medicine or surgery legally in Great

Digitized by Google

Britain or Ireland it is necessary to be enrolled in the Medical Register, and that, to obtain that distinction, it is necessary to study at a College and a Hospital for about four years, and afterwards obtain one or more diplomas by passing one or more examinations in professional subjects.

The first point to be decided is whether the boy is of the proper age for studentship and has received the requisite amount of schooling. As to the first of these points there need not be much apprehension, for although some of the licensing bodies profess by their regulations to accept for their diploma no candidate whose age is less than twenty-one, there is practically no minimum limit of age of the students. But circumstances impose some such limit, because none of the Public Services will appoint to medical office any youth of earlier age than twenty-one, and it is therefore not only useless, but unadvisable, to complete the student's education until he has reached that mature age. Moreover, in England, no student receives credit for any part of his medical study, as counting towards his diploma, until he has passed his preliminary examination in general education, and the average boy will hardly be able to do this until he has passed his sixteenth year. For these reasons the majority of students do not commence their medical studies until they are seventeen or eighteen years of age, in which case they receive their diplomas between their twenty-first and twenty-third years.

The second consideration is whether the boy has been sufficiently schooled, and this is determined by his capacity to pass a recognised preliminary examination in general education. Of such recognised examination the Medical Council publishes a list comprising most of the primary collegiate examinations throughout the world, but as to the extent and gravity of such examinations there are the most extraordinary variations. The principal preliminary subjects of examination are as follows :—

London Society of Apothecaries.—1. The English Language: English Composition.—2. Latin: January, Cicero, *De Amicitiâ;* April—Virgil, *Georgics*, Book iv. September—Ovid, *Metamorphoses*, Book i.; Retranslation of easy sentences; Answers to Grammatical Questions.—3. Mathematics: The Ordinary Rules of Arithmetic; Vulgar and Decimal Fractions; Addition, Subtraction, Multiplication, and Division of Algebraical Quantities; Simple Equations; The First Two Books of Euclid.—4. *a.* Greek: Xenophon, *Anabasis*, Books i. and ii. *b.* French: St. Pierre, *Paul et Virginie;* Translation from English into French. *c.* German: Goethe, *Egmont;* Translation from English into German; Grammatical Questions in each Language. *d.* Natural Philosophy: Mechanics, Hydrostatics, and Pneumatics.

London College of Surgeons, conducted by the College of Preceptors.—Part I. *Compulsory Subjects.* 1. Writing from dictation.—2. English Grammar.—3. Writing a short English composition, such as a description of a place, an account of some useful or natural product, or the like.—4. Arithmetic. No candidate will be passed who does not show a competent knowledge of the first four rules, simple or compound, of Vulgar Fractions, and of Decimals.—5. Geography of Europe, and particularly of the British Isles.—6. Outlines of English History; that is, the succession of the Sovereigns, and the leading events of each reign.—7. Mathematics: Euclid, Books i. and ii.; Algebra to Simple Equations inclusive. 8. Translation of a passage from the second book of Cæsar's *Commentaries De Bello Gallico.*—Part II. *Optional Subjects.* Papers will be set on the following seven subjects; and each candidate must offer himself for examination on one subject at least, at his option; but no candidate will be examined on more than four subjects:—Translations of passages from—1. The first book of the *Anabasis* of Xenophon.—2. X. B. Saintine's *Picciola.*—3. Schiller's *Wilhelm Tell.* The candidate must also answer questions on the grammar of each subject, whether compulsory or optional. 4. Mechanics: chiefly elementary.—5. Chemistry: elementary facts.—6. Botany and Zoology: Classification of Plants and Animals.—7. Euclid, Books iii., iv., v., and vi. The quality of the handwriting and the spelling will be taken into account. Failure in any one subject necessitates re-examination in all.

London University.—Candidates must pass in *a* Latin, *b* English subject, *c* Mathematics, *d* Natural Philosophy, *e* Chemistry, and any two of the following—Greek, French, German, Latin, or Arabic. Latin: one Latin subject, selected by the Senate from the undermentioned—Virgil: one book of the Georgics and of the Æneid. Horace: two books of the Odes. Sallust: The Conspiracy of Catiline, or the War with Jugurtha. Cæsar: two books of the Gallic War. Livy: one book. Cicero: De Senectute or De Amicitiâ, with one of the Orations. Ovid: one book of the Metamorphoses, and one book of the Epistles or Heroides. Latin shall contain passages to be translated into English, with questions in history and geography arising out of the subjects of the books selected. Short and easy. A separate paper shall be set containing questions in Latin grammar. Greek (h): one Greek subject from the undermentioned—Homer: one book. Xenophon: one book. French: passages for translation into English, and questions in grammar, limited (except when German is taken as an alternative for Greek) to the Accidence. Sanscrit: Arabic — translations into English, and questions in grammar. The English language: English history and modern geography, orthography, writing from dictation, the grammatical structure of the language, history of England to the end of the seventeenth century, with questions in modern geography. Mathematics—Arithmetic: the ordinary rules of arithmetic, vulgar and decimal fractions, extraction of the square root. Algebra: addition, subtraction, multiplication and division of algebraical quantities, proportion, arithmetical and geometrical progression, simple equations. Geometry: the first four books of Euclid, or the subjects thereof.

IRELAND.

College of Surgeons.—The English language, including grammar and composition; arithmetic, including vulgar and decimal fractions; algebra, including simple equations; geometry, first two books of Euclid; Greek and Latin, including translation and grammar. Greek: the Gospel of St. John, or the first book of Xenophon's Anabasis, or the Dialogue of Lucian entitled Menippus, or the Necromancer. Latin: the first and second books of the Æneid of Virgil, or the Jugurthine War of Sallust, or the third book of Livy.

College of Physicians.—Holds no preliminary examination.

University of Dublin.—The entrance examination.

Apothecaries Hall of Ireland.—Compulsory: 1. English grammar, composition, and history. 2. Arithmetic and algebra, including simple equations. 3. First two books of Euclid. 4. First two books of Livy or of Virgil's Æneid; translation, prose composition. 5. Greek, first book of the Anabasis or of the Iliad. 6. French or German, Charles XII., Voltaire's Histoire, or Lamartine's Voyage en Orient, or Schiller's Wilhelm Tell. *Optional:* Mechanics, hydrostatics, pneumatics and hydraulics. Classification and structure of vegetables and animals.

Queen's University.—Examination no longer held.

SCOTLAND.

Colleges of Physicians and Surgeons.—1. English language, grammar and composition. 2. Arithmetic, includ-

Digitized by Google

ing vulgar and decimal fractions; algebra, including simple equations. 3. Geometry, first two books of Euclid. 4. Latin, Cicero de Naturâ Deorum; Virgil, Æneid, Book II; grammar, and a passage from an unprescribed author. 5. One of the following optional subjects—(1) Greek, Xenophon, Anabasis, Book III.; and Homer, Iliad, Book III. (2) French, Molière, Les Femmes Savantes. (3) German, Schiller's Maria Stuart. (4) Natural philosophy, including mechanics, hydrostatics, and pneumatics.

Edinburgh University.—1. English, writing a passage from dictation; composition, with correction of sentences of bad English; grammar, history, and geography. 2. Latin, for October 1879 and March 1880, Livy, Book XXIII.; for October 1880 and March 1881, Livy, Book XXII.; an easy passage from a Latin prose author, and a single passage of English to be retranslated into Latin. 3. Arithmetic, the common rules. 4. Euclid, Books I., II., III; and algebra, including simple equations. 5. Elements of dynamics (mechanics), elementary kinematics, statics, kinetics, and hydrostatics: text-book, Blaikie's Elements of Dynamics. At least two of the following subjects—1. Greek, for October 1879 and March 1880, Xenophon, Memorabilia, Book I.; for October 1880 and March 1881, Xenophon, Cyropædia, Book VIII. 2. French, for October 1879 and March 1880, Molière, Les Femmes Savantes; for October 1880 and March 1881, About, La Mère de la Marquise. 3. German, for October 1879 and March 1880, Schiller, Marie Stuart; for October 1880 and March 1881, Goethe, Egmont. 4. Higher mathematics, Euclid, Books I. to VI.; algebra, trigonometry, and conic sections. 5. Natural philosophy, Balfour Stewart's Elementary Physics. 6. Logic, Jevon's Elementary Lessons in Logic, or Fraser's Selections from Berkeley, second edition, pp. 143—249. 7. Moral philosophy, for October 1879 and March 1880, Calderwood's Handbook; for October 1880 and March 1881, Butler's Ethical Theory Sermons, 1, 2, 3. In Latin, Greek, French, and German, questions in grammar will be set, and passages to be translated from English.

Glasgow University.—English, dictation, composition of a short essay, questions in grammar. Latin, Virgil, Æneid, Book IV.; Sallust, De Bello Jugurthino, Chap. 1. Translation of English passages into Latin, questions in grammar and construction. Arithmetic, the common rules. Elements of Mathematics, Euclid, Books I., II., and III.; algebra, as far as simple equations. Elements of mechanics, questions, for which Bottomley's Dynamics may serve as a text-book. Two subjects, to be selected by the candidate. Greek, Cyropædia of Xenophon, Book II., and the Gospel according to St. John. French, Corneille's Le Cid. German, Lessing's Laocoon. Higher Mathematics, Euclid, Books I. to VI.; algebra, including quadratic equations and the rule of trigonometry. Natural philosophy, such a knowledge of the principles as may be obtained from Bottomley's Handbook and Balfour Stewart's Elementary Lessons in Physics. Natural history, geology or zoology. Text-books—Green, Lyell, Dana, Nicholson, and A. Wilson. Logic, Whately's Logic, Books II. and III. Moral Philosophy, the general principles, as stated in Dugald Stewart on the Active Powers, or Dr. Fleming's Manual.

In England, and with most of the Scotch licensing bodies, it is essential that the student shall have passed his preliminary examination before he commences medical study. This is not the case in Ireland, where it is possible, though not usual, for the student to postpone his examination in general education until the eve of his professional examination. If he is either lazy or ignorant, he may adjourn that unpleasant process, *de die in diem*, until the eve of his final qualification as a surgeon, when if he does so, he will find himself in possession of a mental muddle of Latin and physic. The preliminary examination is, however, not to be feared.

We strenuously advise the parents of the student to insist on his passing his preliminary education before he enters a medical school or hospital, and thus the student will relieve his mind of the apprehension of a future examination, which he will assuredly put off to the last moment if he can. In England the four years of medical study required to pass do not commence to count until the preliminary is passed. It should be so in Ireland, but it is not.

The preliminary examination having passed, it becomes necessary to select the method of education to be pursued. It should first be decided what is to be the aim of the student in after-life, for upon that question will depend in great measure the school at which his studies are to be pursued.

THE CHOICE OF UNIVERSITIES AND COLLEGES

Will depend on various circumstances, and on the aspirations of the student. If he is intended to make a fortune and enlighten his generation as a metropolitan practitioner; and if money and education are plenty, he will probably take a University degree in arts and in his profession. If the attainment of good professional rank on moderate terms be desired, the Licenses of the "College and Hall" for London, the Colleges of Surgeons and of Physicians for Ireland, or the Double Diplomas of Edinburgh for Scotland, will serve every purpose. For any University degrees which are of any value, it is to be remembered the student must undertake the prolonged study of classics and science in addition to his medical, surgical, and anatomical studies; and he will have to pay a considerable sum for this course of teaching. But if he is content to face the expense and labour, he will enter the profession with all the prestige of an educated gentleman. In fact, the question whether he will or will not lay out for himself a University graduation in arts and medicine, depends principally whether he has money and time to give to it, and whether or not he means to practise in the metropolis. The University of Durham and some of the Scotch Universities place at the disposal of the student a cheap University degree, and thereby attract many applicants, who are at liberty to write M.D. after their names, and are not called upon for University residence or academic study. These degrees serve as legal qualifications to practise, and pass for an academic Doctorate in Medicine amongs the uninitiated; but this does not confer the *prestige* attached to the degrees of Oxford, Cambridge, or Dublin.

If the student elects to seek a University degree —other than that of the London University—he will, of course, pursue his Arts in Oxford, or Cambridge, or Dublin, and his professional studies *pari passu*. If he is content with simple licences to practise, he must attach himself to a School and Hospital. Here the English and Scotch systems differ widely from that in existence in Ireland. In London, the usual course is for the student to select a School which is suitable to his pocket and his locality of residence, and where he thinks he will get "good value." The School is almost always in immediate connection and on the same premises as one of the hospitals. In Dublin, on the contrary, the Schools—with the exception of Steeven's Hospital School and the School of Physic—have no immediate connection with any hospital, and the pupils of a Dublin School are a hetero-

Digitized by Google

geneous gathering from all the hospitals in the city. In England a composition fee is accepted by many of the Schools, which fee entitles the student to the whole of the curriculum of lectures, dissections, hospital, &c. necessary for his diploma.

The following is a statement of the composition fee payable at each London School from the most expensive to the cheapest :—

Bartholomew's, Guy's, or University College	£131	5	0
King's College, St. Thomas's, or St. George's	125	0	0
St. Mary's	106	1	0
London	94	10	0
Westminster	92	10	0
Middlesex	90	0	0
Charing Cross	88	4	0
Birmingham Queen's College or Manchester Owens College ...	105	0	0
Bristol	99	0	0
Liverpool	86	2	0
Sheffield	81	15	0
Leeds	71	8	0
Newcastle	70	7	0

These fees are close approximations, subject to addition for extras required for certain licenses. The fees may be paid in full at the entering of the student, or they may be paid in certain fixed instalments at the beginning of the successive periods of study, by which system the total payment is something larger than those above quoted. It will thus be observed that, in England the student is encouraged to enter at a particular school and hospital, and to take his whole education there, and, as a matter of fact, the great majority of students follow this course. It has its advantages, not the least of which is that it places the student under the absolute control of his teachers, and enables them to dictate his method of learning, and to supervise his diligence to a much greater extent than is possible elsewhere.

In Ireland, on the contrary, composition fees are a rare exception to the rule. The student goes to any school he pleases and any hospital he pleases, and enters his name for any number of lectures he pleases. If he does not like his school or hospital, he most probably migrates to a rival institution on the first opportunity. It is, in fact, but seldom that an Irish student confines his studies to a single hospital and, in order that he may be perfectly free to seek his education where he thinks he can best obtain it. It has been recently decreed by the Dublin hospital surgeons, on the suggestion of Professor Haughton, that perpetualism be abolished, and that no discount be allowed to students in consideration of their taking out their entire time at one institution.

The Irish system is open to grave abuses, which need not be dwelt on at present ; but it has certainly the great merit of rendering the student perfectly independent, and forcing schools to compete energetically for a continuance of his patronage. It will be obvious, however, that the system which enables the student to pay a lump sum, and thus relieve himself of the trouble of entering for lectures, and paying fees in detail, is a convenient one, especially for the beginner, who is altogether ignorant of the system, and therefore the requirement which is provided for in England by the dean of the school, is met in Ireland by individual teachers or "apprentice" holders.

COST OF EDUCATION.

Should the student proceed on his own account, the lectures necessary for the diplomas of the Colleges of Physicians and Surgeons in Ireland, will amount to £65 ; hospital attendance, according to the new scale of fees, £36 ; lying-in-hospital from £4 4s. to £7 7s. These, with the diploma fee of £25 5s., which both in England and Ireland is additional to the fees which we have enumerated, represent the essentials. The sum of £50 paid down at the commencement is taken by the school of the Irish College of Surgeons as payment in full for all lectures requisite. The system of perpetual pupilage and discount of fees at hospitals has, as we have said, been abolished. Thus the absolute payment will amount to somewhere about £93, taking the minimum mode of payment. In addition to this sum are to be considered the payment for "grinding" or "coaching," a process almost universal, but by no means necessary to any industriously inclined student. The fixed sum is at present for private teaching £15 15s. for the surgical and medical qualifications, and £5 5s. for pharmacy, &c. Should the candidate "grinding" for the army and navy examinations, a fee varying from £10 to 10s. to £21 is, we believe, usual. Should the candidate perform operations on the subject as a practice, they will cost something extra. So that, assuming the extras or voluntary costs are incurred, the total will vary, say from £120 to £140 on a moderate scale; it is, of course, to be expected that pupil holders should have some extra payment ; we therefore might name for them 160 guineas.

This sum, or something like it, will secure to the pupil the advantage of being "apprenticed" to a teacher who will undertake all monetary responsibility for his education, and may be able to give him some special advantages as his own pupil at hospital ; but it must, we fear, be confessed that the so-called apprenticeship is sometimes a simple contract for payment of fees, and involves but little of that special teaching which is due by a master to a true apprentice. Most of the apprentice holders will accept payment by instalments.

PAYMENT OF FEES.

If the student is his own manager, he must enter his name with the secretaries of the school and hospital, and pay for the lectures and hospital he intend to take out. If he is wise he will not adjourn the majority of his lectures, as he may, to the next year, but will take in his first year a full third of his curriculum. He is *supposed* to pay the professor's fee or hospital fee in full on entering his name, but few students do so ; and many, we are sorry to say, are in the habit of entering for the minimum allowable number of lectures, and paying the minimum allowable proportion of the fee, putting off the attendance perhaps for ever, certainly until the last moment, and adjourning the payment until it becomes necessary to take up the certificates.

By a most objectionable laxity of system a student may get credit for one of his four years of attendance by paying a couple of guineas for dissections, and he may think himself safe in doing so if money be scarce ; but if he does not pay his full third or fourth of the fees each year it often happens that he has to put off his examination from year to year—perhaps for ever—for want of money to pay the accumulated fees of previous years.

Having thus entered his name as a medical student, and acquired his right to commence study, his next business is to register himself as such on the General Medical Council.

To this body is entrusted the supervision of Medical Education, and it has made a number of recommendations, the majority of which have been accepted by all the Examining Bodies, and are, consequently, found in their regulations. The student has, therefore, nothing to do with the Council, except that he must take care to be duly registered as a Student in Medicine, *at the commencement of his career*, at the offices, 315 Oxford Street, London, or at the offices of the Branch Registrar of the division of the United Kingdom in which he is residing. He must in England previously have

Digitized by Google

passed a preliminary *Arts Examination*, of which we have given the details above. With regard to registration, each English student should apply according to a form, accompanied by a certificate, of his having passed such examination, the same to be lodged with the Registrar, who will thereupon enter the same in the Students' Register, and issue a certificate to that effect. It should be recollected that this commencement of the course of professional study is not reckoned as dating earlier than fifteen days before the date of registration.

The intention of this registration is to ensure that the student shall occupy four years in medical study, which is, theoretically, the period which must be devoted to his education before his entry to the profession. In England this requirement is set down as essential, and no student can present himself for examination sooner than four full years from the date of registration, but the obligation to occupy this period in medical study is frequently satisfied by a nominal service for the first year under a general practitioner, or in a provincial hospital or dispensary, and the actual period of medical study is often really three years. Recently, however, the several qualifying bodies are recommended by the Medical Council not to admit to the final examination for a qualification under the Medical Acts any candidate whose name has not been registered at least forty-five months previously. Besides, the standard of medical education, as well as of the examinations of various examining bodies, is so much higher than it formerly was, while our own knowledge of medicine and the collateral sciences, and the scope of our medical studies have recently become so enlarged that four years is by no means too long a period to be devoted to medical study. And even the diligent student will find that at the expiration of this term he will have but an imperfect acquaintance with several branches of his profession.

In Ireland the registration of medical students is very irregular and unsatisfactory. No pupil thinks of giving himself any trouble about the matter, and leaves it to the Registrar of his School to return to the Branch Medical Council the names of his *alumni* which, for reason the iniated understand, he frequently forgets to do. Inasmuch, therefore, as there is, in Ireland, no legal date for commencement of medical study, there is no means of judging whether the nominal four years of medical study are, or are not, actually occupied in learning the profession, and, as a matter of fact, few students do devote that period to their work, though many of them continue in the nominal study of medicine for as long as seven or eight years.

DATES IN ENGLAND AND IN IRELAND.

The entry of names and commencement of study in Ireland is supposed to date from the first of October in each year, but the Session really does date from the 1st of November, and the entry of names may be delayed by the dilatory until the 25th of the same month.

The student then begins work, attending hospital each morning at nine o'clock, and occupying his day from half-past eleven to five between lectures and dissections. His holidays—if the term be not ignoble—are a fornight at Christmas, and a week at Easter, and he finally returns home at the end of July.

ATTENDANCE ON LECTURES.

The average Dublin student is supposed to attend of necessity, and irrespective of voluntary courses, twelve courses of lectures, six of them extending over six months, and six over three months, making a total of 52 months lecturing. In addition to this he is presumed to dissect and hear demonstration, say an hour-and-a-half daily, for eighteen months, to attend hospital, for at least a couple of hours daily for twenty-seven months. To serve in the chemical laboratory for three months, and in the majority of cases to attend the "grind" for at least eighteen months for two more daily hours. He cannot, if moderately industrious get on with less than two hours reading per day, and he may have during the same period to work up his business for the "Preliminary," or his Arts Course in the University. This curriculum—taking the lectures on an average of four days weekly—represents nearly five thousand hours close work to be got through in three working years of about seven months (allowance being made for Christmas and Easter and summer holidays).

Thus it will appear that the student, to fulfil the nominal requirements of his education in Dublin, must work very nearly nine hours daily—*i.e.*, from after breakfast to about seven p.m. It is hardly necessary for us to say that even the most avaricous medical bookworm does not attempt such a task. Necessarily the attendance on many of the courses of lectures is nominal in amount. The University of Dublin insists on an attendance of three-fourths of the number of the required lectures, but other licensing bodies accept as "diligent" attendance the presence of the student at all—a few—or none of the lectures which the student pays for. It would be manifestly ridiculous for them to demand *bonâ fide* compliance with the regulations, and thus it happens that the student being hopeless of attending at—often attends—scarcely any of the lectures which are supposed to form the chief part of his education. The average student thinks himself exemplary if he works his hospital, dissections, demonstrations, physiology, lectures, and grind, and drops in occasionally to the other courses.

The progress of each year is the same, except that he usually devotes more attention to the "grinding," dissection, and hospital dressersships, and less to lectures in his later years of study. At the end of his second year he will take his "first half" examination, and by so doing relieve himself, in a great measure, of the study of anatomy, and be in the position of devoting his third year to surgery and medicine. After the expiration of his third session, his student life, whether it begin in laziness and end in a hurry and incompetency, or whether it commence in diligence and end in the confidence of proficiency, ends with the last examination, and he goes forth into the world either an ignoramus or a reliable surgeon, whichever his choice may have been.

THE STUDY OF VACCINATION IN IRELAND.

During the past year the Royal College of Surgeons in Ireland has ordered that, on and after August 1, 1879, no candidate for letters testimonial shall be admitted to examination without producing a certificate of attendance for one month at the Cow-pock Institution, or some other institution to be approved of by this Council, under the instruction of a public vaccinator specially recognised by this College for the purpose, and that he is practically acquainted with vaccination.

Any public vaccinator, holding office under the Local Government Board for Ireland, may be recognised by the Council as entitled to grant the certificate. The instruction include—1. The performance of the operation of vaccination. 2. The conditions of the patient which contra-indicate vaccination. 3. The characteristic appearances of the vaccine disease at the different stages of its course, and the deviations therefrom, which are compatible with its protective influence. 4. The taking of lymph and the method of preserving it in tubes or on points; and of recognising impurities. The candidate shall be liable to be examined upon these subjects at his final examination.

REGISTRATION OF PRACTITIONERS.

All duly qualified Physicians, Surgeons, Medical Graduates, and Apothecaries are required by the Medical Act 21 and 22 Vic., c. 90, to be registered before they can hold any public medical or surgical appointment, or issue valid medical certificates.

The medical registration of any practitioner may be effected on personal application or in writing (according to a form to be had in London or at either of the Branch Offices). With such application he must produce or transmit the *Diplomas* to be registered, and also pay or remit the fee, which is regulated by the Medical Council—viz., £5 for the first registration, and 5s. for every qualification which may be subsequently added. Each practitioner is entitled to receive a copy of the official Medical Register containing the registration free on application.

THE UNIVERSITIES.

Oxford and Cambridge.

As there are generally few candidates for the degrees of these Universities, we shall make our remarks as brief as possible.

Every student in medicine must pass all the examinations for the degree of B.A., and date the commencement of his medical studies from the final examination for arts. Candidates for the degree of B.M. are required to pass two examinations, embracing the usual subjects. At the second examination he is examined in two of the ancient authors—Hippocrates, Aretæus, Galen, and Celsus—and in some modern authors, as Morgagni, Sydenham, or Boerhave. He must spend two years in study prior to the first or scientific examination, and two years more after passing the first, prior to the final examination for the same degree. A dissertation has to be publicly read three years after obtaining the M.B., before being eligible for the M.D. The medical examinations take place annually in Michaelmas term.

Scholarships of about the value of £75 are obtainable at Christ Church, Magdalen, and other Colleges, by competitive examination in natural science. Each year, a Radcliffe travelling fellowship is competed for by anyone who, having taken a first-class at any of the public examinations of the University, or having obtained some University prize or scholarship open to general competition, proposes to graduate in medicine. The travelling fellows receive £200 a-year for three years, half this period being spent in study abroad.

At the University of Cambridge, five years of medical study are required, unless the student has graduated with honours as A.B. For the M.B., he must have resided nine terms in the university, and have graduated in arts. There are three examinations for this degree. The first is in chemistry, physics, and botany; the second, in anatomy (human and comparative), physiology, and pharmacy; and the third, in the usual practical subjects. After the third examination an Act has to be kept, which consists in reading an original thesis, followed by an oral examination on the subject of the thesis. The M.D. degree may be taken three years after the M.B. An Act has to be kept, with oral examinations, and an essay has to be written *extempore*. There is also a degree of Master in Surgery, for which the candidate has to attend extra courses of lectures on anatomy and surgery. An examination in so much of State Medicine as is required by medical officers of health, will be held in October, 1879. With respect to Cambridge (and almost the same remarks apply to Oxford), a residence during nine terms—*i.e.*, the greater part of each of three years—is by statute requisite to obtain any degree in arts, medicine, or any other subject. The actual cost of this to a student who keeps his terms by residence in a college is from £150 to £200 a year. This, however, would include all payments to the university and the college—all fees, as well as clothes, pocket money, travelling expences, &c. But the non-collegiate students have only to pay the university fees, which are very small. They lodge and board as they like, and their expenses, therefore, are entirely in their own hands.

London University.

The London University is a convenient portal to the medical profession, since through it a man can become a legally qualified "Doctor" of Medicine without being compelled to spend the time and money required to enable him to yield compliance with the exactions of "residence" during their academical years insisted on at the older universities of Oxford and Cambridge.

Provided he presents himself, mentally and practically, fitted to undergo the examinations successfully, it makes no difference to his chances before the board, where his studies may have been prosecuted, provided always that this place be some duly recognised centre of medical education. Moreover, the technical training must commence subsequently to the passing of the matriculation examination; and it must be added that the tests to which candidates are submitted in the proper professional parts of the examination for the M.B. degree, are severe and searching. A wide and thorough reading, and an extensive practical acquaintance with routine medical and surgical work, are necessary to insure success, at Burlington House; and to this fact is due the high estimation in which the London degrees are held by the members of the medical profession, to whom their nature is more or less familiar. Among outsiders, however, with whom the mere letters attached to a name make the criterion of comparison, the significance of M.D. Lond. is neither more nor less than M.D. Edin. or Cantab. This want of appreciation by the general public, does not, in any measure, detract from the high value attaching to the London degree, and every student of ambition who is debarred from obtaining the doctorate of the more venerable universities, will do well and wisely in pursuing the wide studies necessary to enable him to earn the coveted distinction. The mental training is undoubtedly a valuable exercise, and can react only for good; good that will be continually evident in all his late experience, and that will tend to his own personal elevation, and the general improved tone of the profession whose interest is his individual concern. We would strongly recommend those students who intend to graduate at the London University to so arrange their studies as to pass the preliminary scientific examination *before commencing their regular medical studies*, taking a preliminary year for the purpose of preparation. In this way much knowledge will be gained which will go to clear the way for his first year's studies, which would otherwise be much encumbered.

The preliminary scientific examination commences on the third Monday in July, and no candidate is admitted to it unless he has completed his seventeenth year, and has passed the matriculation examination. The subjects on which he will be examined, are—Inorganic chemistry, experimental physics, botany, vegetable physiology, and zoology. Candidates who shall pass in all these subjects, and shall also pass at *the same time* in the pure mathematics of the first B.Sc. examination, or shall have previously passed the first B.A. examination, shall be considered as having passed the first B.Sc. examination. There are in this, as in every other stage of the graduate's career, examinations for honours, which afford the student the opportunity of gaining highly-prized distinctions in various branches, such as valuable scholarships, exhibitions, and prizes. The medical and scientific degrees of the University are—Bachelor and Doctor of Medicine, Bachelor and Master in Surgery, and Bachelor and Doctor of Science. For the regulations respecting these examinations the student should apply to the Registrar of the University.

It has come to be generally felt that scientific knowledge, to be real, must be practical as well as theoretical, and that a thorough knowledge limited to a comparative small range is preferable to a slighter acquaintance spread over a more extended area. In the first examination for Bachelor of Science, which every candidate will be required to pass, the programmes in mathematics, experimental physics, and inorganic chemistry, have been carefully revised. In place of the superficial acquaintance with both zoology and botany formerly required at this examination, there is a single examination (written and practical) in general biology, in which a more thorough knowledge is required of the simplest forms and elementary phenomena of animal and vegetable life. The regulations for the second B.Sc. examination, on the other hand, are framed with the view of allowing the candidate to bring up any three of the following nine subjects:—(1) Pure mathematics, (2) mixed mathematics, (3) experimental physics, (4) chemistry, (5) botany, including vegetable physiology, (6) zoology, (7) animal physiology, (8) physical geography and geology, (9) logic and psychology. Moreover, in the matricular examination which forms the basis of the science curriculum, German may now be taken in substitution for Greek. In regard to the Doctor's degree, a change has been made in favour of candidates who prolong the interval between their first and second examinations for the degrees of Bachelor from one year to two or more, as such will be allowed to come up for the degree of Doctor of Science within a year of their attaining the degree of Bachelor.

A special examination is held once in every year in subjects relating to public health, to which those candidates only are admitted who have passed the second M.B. Examination at least one year previously. Candidates will be examined in chemistry and microscopy, as regards the examination of air, water, and food; meteorology, geology, physics and sanitary apparatus, vital statistics, hygiene, and sanitary laws, full particulars of which may be obtained from the Registrar.

All the medical degrees of the London University are open to women, and valuable scholarships have been founded for their special benefit.

Digitized by Google

University of Durham.

Two licences and three medical degrees are conferred by this university—viz., Licences in Medicine and Surgery, with degrees of Bachelor of Medicine, Master of Surgery and Doctor of Medicine. A certificate of proficiency in sanitary science is also awarded.

With regard to the degree of Bachelor of Medicine, no one will be admitted to that degree unless he has kept one year's residence at the Durham University College of Medicine, and in the case of non-university men an additional arts examination to the professional examination must be passed. There are two examinations for the M.B.

No grace for the degree of Doctor of Medicine will be granted unless the petitioner is a Bachelor of Medicine of the standing of twenty-one terms (seven years) at least from his registration or matriculation, and of three terms at least from his admission to the degree of Bachelor of Medicine, nor unless he has written an essay based on original research or observation on some medical subject selected by himself, and approved of by the Professor of Medicine.

There is also an examination and a certificate of proficiency in sanitary science. Hospital practice can be attended at the Newcastle infirmary, which contain 230 beds. There are four scholarships of 25*l* a-year, tenable each for four years. Dickinson Memorial Scholarship, 15*l*, tenable for one year, for general proficiency. Tulloch scholarship, 20*l*, tenable for one year, for anatomy, physiology, and chemistry. Charlton memorial scholarship, 35*l*. tenable for one year, for medicine. Gibb scholarship in pathology, 20*l*, tenable for one year. Four resident dressers, who also act as physicians' clinical clerks, are chosen every six months from the senior students. Fee for six months' board and residence, 10*l* 10*s*. Two assistants in the pathological department are chosen every six months. At the end of each session a silver medal and certificate of honour will be awarded in each of the required classes.

With regard to fees, a composition fee for all the Lectures, payable on entering to the first winter session, 52*l* 10*s*. Separate courses of lectures, each 4*l* 4*s*. Twelve months' hospital practice, 7*l* 7*s*; six months, 5*l* 5*s*; three months, 4*l* 4*s*; perpetual fee, 17*l* 7*s*; or, if paid by instalments, first year, 7*l* 7*s*; second year, 6*l* 6*s*; third year, 5*l* 5*s*. These fees also are payable in advance.

Foreign Universities.

Next week we shall devote a brief chapter to "Foreign Degrees and How to obtain them," giving information much sought for, but not readily obtainable in this country, together with the routes and fares to and from the different university towns of the continent.

The Royal College of Physicians of London.

The high position which this venerable College holds among the corporations is too generally acknowledged to need that any particular attention should be drawn to it. It is gratifying to know that this College has lost none of its prestige by sympathising and becoming more as ociated with the general body of practitioners. Its license is an honourable one, and we are surprised that students are not more ambitious than they are to enter the profession through its portals.

The Fellowship.—The Fellowship of the College is attainable only by election, and no one can be proposed who is not a member of at least four years' standing.

The Membership.—A person may become a member without holding a degree in medicine, or, indeed, any diploma. But every candidate who shall have commenced his professional studies after September, 1861, shall satisfy the Censors Board that previous to such commencement he has obtained a degree in Arts from some university of the United Kingdom or of the Colonies, or from some other university specially recognised by the Medical Council, or that he has passed examinations equivalent to those required for a degree in Arts. The curriculum extends over five years.

The following additional regulations for the membership came into force on Jan. 30th, 1878:—1. Any candidate who shall produce satisfactory evidence of having passed an examination on chemistry and materia medica, required for a degree in medicine at a university in the United Kingdom, in India, or in a British colony, will be exempted from re-examination on those subjects. 2. Any candidate who has already obtained the degree of Doctor or Bachelor of Medicine at a university in the United Kingdom, in India, or in a British colony, or who shall have obtained a qualification entitling him to practice medicine or surgery in the country where such qualification has been conferred, wherein the course of study and the examinations to be undergone previously to graduation shall have been adjudged by the Censors' Board to be satisfactory, shall be exempt (if the censors shall think fit) from all or any parts of the examinations hereinbefore described, except such as relate to the third or pass examination.

Graduates in medicine of any British university are admitted to an examination for the membership. Such graduates are exempt from some parts of the examination—*e.g.*, anatomy and physiology. Even graduates of accredited foreign universities have no difficulty in being admitted to examination. All persons who have been admitted before February 16, 1859, licentiates of the College, and also all extra-licentiates who are not engaged in the practice of pharmacy, may be proposed to be admitted a member of the College. Every candidate for the membership is expected to pass an examination, but there are certain cases, referred to under sections 15, 16 and 17 of the bye-laws of the College, in which the candidate is exempted from some portion of the examination.

The Licence.—The Licence of this College is a qualification to practise medicine, surgery, and midwifery, and is recognised by the Poor-law Board as a qualification in surgery as well as in medicine, but unless a graduate of some university he is forbidden to use the title of doctor; we regret, however, many do so. It was regarded at first as a diploma for the general practitioner, intended to supersede that of the Apothecaries' Company. The examination is conducted by specially-appointed examiners, and is complete in the several departments. There are two examinations for the licence, the *first* of which may be passed after the termination of the second winter session, while the *second* examination cannot be passed until after four years of professional study. The fee for the College Licence is fifteen guineas, of which five are to be paid on admission to the first examination.

Every candidate will be required to produce satisfactory evidence of having completed the course of study in accordance with the bye-laws and regulations of the College, which may be obtained of the Registrar, and to pass the professional examinations conducted by the Examining Board.

Any candidate who shall produce satisfactory evidence of having passed an examination on Chemistry and Materia Medica, required for a degree in medicine at a university in the United Kingdom, in India, or in a British colony, will be exempted from re-examination on those subjects. Any candidate who shall have obtained a qualification which entitles him to practise Medicine or Surgery in the country where such qualification has been conferred, after a course of study and an examination equivalent to those required by the regulations of the College, shall, on production of satisfactory evidence as to age, moral character, and proficiency in vaccination, be admissible to the pass examination, and shall be exempt from re-examination on such subjects as shall in each case be considered by the Censors' Board as unnecessary.

Royal College of Surgeons of England.

No College has exercised more influence over the profession than this. Without the M.R.C.S. it is not easy to obtain any English surgical appointment. Its membership, although no longer essential, yet carries great weight in a parish appointment. For this reason most English students take this diploma, which, together with a medical qualification, suffices for every purpose of the general practitioner. The College gives four diplomas—the membership, fellowship, a diploma in dental surgery, and one in midwifery, which last is, however, mostly confined to those who are already members.

The Membership.—This diploma gives no vote in the affairs of the college. It is only a licence to practise, and corresponds with the licentiateship of the Edinburgh and Dublin Colleges.

In future, candidates for the diploma will be examined in the practice of medicine, although there are certain conditions on which he can claim exemption. He must have passed the preliminary examination of the or one that is recognised by the College. two professional examinations for the Primary and the Pass.

The Fellowship.—Members admitted to the Fellowship grade is obtainable

Digitized by Google

and needs no personal influence, men who have sufficient time and ability prefer the F.R.C.S. after exam.

For the Fellowship he must be a Member of the College of eight years' standing, and is admitted to examination on producing a certificate signed by three Fellows to the effect that he has been engaged in the Practice of Surgery for eight years, and is a fit and proper person to be admitted as a Fellow.

Few consulting surgeons in England are without the Fellowship, and in most of the London hospitals appointments are unattainable without it.

MEDICAL SCHOOLS OF LONDON.

THERE are in the metropolis eleven medical educational centres. Each of these comprises a fully appointed hospital, with medical school attached. The student, who is doubtful as to which he shall direct his steps, will be much puzzled how to decide on the one most likely to benefit him in the prosecution of his medical studies. In determining this point he should avail himself largely of the advice to be obtained from those conversant with the merits of the different institutions, and, especially will he be wise to pay every heed to students senior to himself. Naturally every man so appealed to will declare his own *alma mater* to be *the* best school, but in spite of this, the partial information so obtained will be of great value, supplimented as it always should be by personal inspection of the institutions themselves. The country candidate will always find the most courteous readiness, on the part of the officials at the various hospital schools, to lend him every assistance in ascertaining the advantages connected with each particular place; and before definitely selecting the hospital he will enter, the student should adopt the plan we have suggested. In many instances his choice will be guided by tradition and association. It may be, father or brother has been at one or other place, and as a matter of course, the connection re-formed with it is maintained This should be so. We write, however, more especially for the guidance of those who are called upon to decide for themselves, and we repeat the suggestion we have made—hear all you can, and finally act on your own judgment and experience.

The London schools are the following:—Guy's, St. Bartholomew's, St. George's, King's College, the London, the Middlesex, St. Mary's, Charing Cross, the Westminster, University College, and St. Thomas's, and we shall notice them in alphabetical order.

The above are for men only. There is also a Medical College for Women, in full operation, in Henrietta Street, Brunswick Square. The clinical instruction is given in the wards of the Royal Free Hospital.

APPOINTMENTS, PRIZES, NEW SCALE OF FEES, &c,

ST. BARTHOLOMEW'S HOSPITAL.—*Appointments:* Four house-physicians and four house-surgeons are appointed annually without fee; each is provided with rooms and receives a salary of £25. Scholarships, &c.—Three Warneford scholarships, each of the value of £25 per annum, two tenable for three years, and one tenable for two years; one Warneford scholarship of £25 per annum, tenable for two years, open to resident students; three junior scholarships of £20 each, tenable for one year, and open to students of the first year; one second year scholarship of £30 tenable for one year, and open to students of the second and third years; the senior scholarship of £40, tenable for two years, and open to students of the third and fourth years; Daniell scholarship of £20 per annum, tenable for two years, for work in the chemical laboratory; two Sambrooke registrarships, each of £50 per annum; one science exhibition of £100; two Warneford prizes of £25 and £15 respectively; Leathes prize; Todd medical clinical prize; Jelf medal; Tanner prize of £10 for obstetrics. Class prizes, each of the value of £3, are awarded annually in particular subjects.

Scale of Fees.—Payment for the entire course of hospital practice and college lectures may be made in one sum, viz., £125 on entrance, or by the following instalments:—£60 on entrance, £50 at the beginning of the second winter session, and £25 at the beginning of the third winter session. Fees for the dental course, £95 1s. 6d.

LONDON HOSPITAL.—*Appointments:* The resident and other hospital appointments are free to full students. The resident appointments consist of five house-physiciancies, four house-surgeoncies, and one accoucheurship; also two dresserships and two maternity assistantships.

Scholarships, &c.—Two entrance science scholarships, value £60 and £40, and two Buxton scholarships, value £30 and £20, will be offered for competition at the end of September to new students. Entries on or before September 20th. A scholarship, value £20, in human anatomy, to first year's students; a scholarship, value £25, in anatomy, physiology, and chemistry, to second year's students; a scholarship, value £20, in clinical medicine; a scholarship, value £20, in clinical surgery; a scholarship, value £20, in clinical obstetrics; the Duckworth Nelson prize, value £10 (biennial), in clinical medicine and surgery. Prizes, value £60, to dressers of out-patients, in minor surgery.

Scale of Fees.—Perpetual fee for lectures and hospital practice, and two years' practical anatomy, payable in three instalments of 40, 35, and 25 guineas, at the commencement of the 1st, 2nd, and 3rd years respectively, 100 or if in one payment 90 guineas. Composition fee for students entering at or before the beginning of their second winter session, their first year having been spent elsewhere, payable in two instalments of 40 and 35 guineas, 75 guineas; or if in one payment, 70 guineas. Perpetual fee for lectures alone, 50 guineas; perpetual fee for hospital practice alone, 50 guineas; dental students (general hospital practice and lectures), 40 guineas; perpetual fee for dental practice, 10 guineas.

ST. MARY'S HOSPITAL.—*Appointments:* There are four resident medical officers, three of whom are appointed for twelve months, and one, the obstetric officer, for six months; all of them live, free of every expense, in the hospital. Two prosectors, appointed annually; a demonstrator of anatomy, a medical tutor, and a resident registrar, each with a salary of £100 a year, appointed annually, and eligible for re-election. Clinical clerks and dressers.

Scholarships, &c.—Two scholarships in natural science, tenable for three years; an exhibition in natural science of £20, tenable for one year; a scholarship in anatomy of £20, tenable for one year; a scholarship in pathological anatomy of £40, tenable for one year, At the end of each session prizes ranging in value from £2 2s. to £4 4s. are given for proficiency in particular subjects.

Scale of Fees.—For unlimited attendance on lectures and hospital practice, 125 guineas if paid by instalments, or 119 guineas if paid in one sum. Fee for hospital practice and lectures required by the examining bodies, 107 guineas in instalments, or 101 guineas in one sum. Fee for dental students, 62½ guineas.

MIDDLESEX HOSPITAL.—*Appointments:* Two house-surgeons, three resident physician's assistants, resident obstetric physician's assistant. The above officers have residence and board in the hospital free of expense, but they pay on appointment fees varying according to circumstances from 10 to 30 guineas.

Scholarship, Etc.—Two Broderip scholarships of £30 and £20 per annum respectively, tenable for two years, for medicine and surgery; two entrance scholarships of £25 and £20 per annum respectively, tenable for two years; John Murray medal and scholarship, awarded every third year; the Governor's prize of £21; clinical prize of £10 10s.; class prizes in particular subjects.

Scale of Fees.—General fee for the entire course of hospital practice and lectures, £90, if paid in one sum on entrance or by instalments of £35, £35, and £20, payable at the commencement of the first, second and third years respectively, and £10 for every additional year's attendance. Course of dental surgery, £42, payable in two instalments of £26 5s. and £15 15s.

ST. THOMAS'S HOSPITAL.—*Appointments:* Two house-physicians, two house-surgeons, a resident accoucheur, two assistant house-physicians, and two assistant house-surgeons, holding office for three or six months. The assistants are non-resident, but the other officers are provided with rooms and commons in the hospital free of expense. An ophthalmic clinical assistant, with salary of £50; surgical ward clerks, clinical clerks and dressers to in-patients and out-patients, obstetric clerks, two hospital registrars, each with a salary of £100; assistants in the dissecting room, prosectors, pathological assistants, and assistants in the physiological laboratory.

Scholarships, &c.—Two entrance scholarships in natural science of £60 and £40 respectively; for first year's students, the William Tite scholarship of £30, and five college prizes ranging in value from £5 to £20; for second year's students, the Musgrove scholarship of £42, and five college prizes ranging in value from £5 to £20; for third year's students, three college prizes of £20, £15, and £10 respectively. In addition there are awarded the Cheselden medal for surgery, the Mead medal for medicine, the Solly medal for reports of surgical cases, the Grainger testimonial prize of £20 for a physiological essay, and the Treasurer's gold medal for general proficiency.

Scale of Fees.—For the entire course of hospital practice and lectures, £125, paid on entrance; or £130 in two payments, £70 on entrance, and £60 at the beginning of the next year; or by three instalments, of £60, £50, and £30, at the beginning of the first, second, and third years, respectively. The fee for the attendance on the *general* subjects required of students in dental surgery is for the two years £45, or by instalments; £50 for the first year, and £10 for the second year.

UNIVERSITY COLLEGE HOSPITAL.—*Appointments:* Six physicians' assistants, six house-surgeons, and four obstetric assistants, are selected annually by examination from among the senior students without additional fee. They reside in the hospital, paying only for their board, and have charge of the resident patients in the absence of the physicians and surgeons. The offices of physicians' clerks, surgeons' dressers, surgical ward clerks, and ophthalmic surgeons' assistants, are selected from among the pupils who are also students of the college, without additional fee.

Scholarships, &c.—Three entrance exhibitions of £30, £20, and £10 respectively, tenable for two years; Atkinson-Morley surgical scholarship of £45 a year, tenable for three years; Atchison scholarship, value about £55, tenable for two years; Sharpey physiological scholarship, value about £70 a year, tenable for three years; Filliter exhibition for proficiency in pathological anatomy, value £30; Dr. Fellowes' clinical medals; the Liston gold medal; Alexander Bruce gold medal; Cluff memorial prize; class medals, &c.; gold and silver medals, or other prizes, as well as certificates of honour, are awarded, after competitive examinations in particular branches of study. Prizes to the value of £10 will be given in the class of hygiene.

Scale of Fees.—125 guineas, if paid in one sum at the commencement of the course, or 130 guineas if paid by instalments, as follows: first year 60 guineas, second year 50 guineas, third year 20 guineas. Hospital practice and

Digitized by Google

clinical instruction, perpetual, £36 15s.; one year, £15 15s.; six months, £10 10s. Practical pharmacy, three months, £5 5s.

WESTMINSTER HOSPITAL.—*Appointments:* There are numerous dresserships and clerkships; the posts of medical and surgical registrar, each with £40 a year, and of house-physician, house-surgeon, resident obstetric assistant, assistant house-surgeon, physician's assistant, surgeon's assistant, ophthalmic assistant, and assistant in the skin department.

Scholarships, &c.—Entrance scholarships next October.—The Fence, £50 a year for two years, and two others value £50 and £20. Subjects—Latin, Mathematics, French or German, and Chemistry and Natural Philosophy. The Latin books the same as the June examination of the University of London matriculation—Ovid: Epistola ex Ponto. Book II. There are also—an exhibition, value £10 10s., for first year's men; a scholarship in anatomy and physiology, value £21, for second year's men; prize for clinical medicine and surgery of £5 each; the Frederic Bird medal and prize, value £15; the Chadwick prize for proficiency, value £21.

Scale of Fees.—In one payment, £92 10s.; in two payments of £49 each, payable on entrance and at commencement of second year respectively; by payments distributed over five sessions, amounting to £107 2s. There are no extras, except parts for dissection. Fees for shorter periods or for single courses, may be learned on application to the Dean. Fees for dental students, payable in one sum on entrance, £45.

SPECIAL SCHOOLS.

LONDON SCHOOL OF MEDICINE FOR WOMEN.

The winter session of 1879-80 opens on the 1st October. Dr. T. K. Chambers will give the inaugural address in the school, at 3 p.m. (30 Henrietta Street, Brunswick Square). The fee for the ordinary curriculum of non-clinical lectures is £80, if paid in one sum, or if paid in instalments, £40 for the first year, £30 for the second, and £15 for the third. The courses of lectures included in this fee are as follows:—Two courses each of anatomy, practical anatomy, physiology, and practice of medicine, and one course each of botany, chemistry, practical chemistry, materia medica, surgery, pathology, midwifery, diseases of women and forensic medicine. Certain classes are held annually, others biannually. The fee of £90 entitles a student to attend, in addition to the classes enumerated above, one course each of practical physiology, zoology, ophthalmic surgery, mental pathology, and hygiene. The London School of Medicine for Women is now recognised by the King and Queen's College of Physicians, Ireland, and by the University of London. Students of the school can therefore proceed to the examination for the license to practise medicine of the college, and for the degrees of M.D. and M.S. of the university. The fee for hospital instruction, which includes annual courses of clinical medicine and clinical surgery, is £20 for the first year and £15 for each subsequent year. Clinical clerks, surgical dressers, are selected from among the senior students without further fee. Two entrance scholarships, value respectively £30 and £30 per annum, for three years, will be competed for at the school on the 24th and 25th September. Fifty-six ladies have already entered the school. Some of these having obtained their licence and degrees are in practice in Edinburgh, Birmingdam, Leeds, and elsewhere. It was the object of the founders of this institution to provide for Englishwomen the opportunity of obtaining a complete medical education in Great Britain. This object has been steadily kept in view, and the curriculum is carried out with a thoroughness equalling that of the best London schools. Students come to it from all parts of Great Britain, as well as from India, Australia, the Cape, and Canada, showing that the advantages offered by this school are appreciated in all parts of the Empire, so that the experiment for testing the aptitude of women for the practice of the profession of medicine is likely through its instrumentality to be thoroughly tested.

LONDON SCHOOL OF DENTAL SURGERY.

This institution is situated in Leicester Square. The meetings of the Odontological Society are also held here. In winter, lectures are delivered on mechanical dentistry by Mr. J. S. Turner, on Wednesdays, at 7 p.m.; on metallurgy in dentistry, by Mr. G. H. Makins, on Tuesdays and Fridays, at 12 o'clock. In summer Mr. A. Coleman lectures on dental surgery and pathology, and Mr. C. S. Tomes on dental anatomy and physiology. General fee for special lectures required for the curriculum, £15 15s. The Saunders scholarship of £20 per annum, and prizes, are open for competition. In connection with the above is the

DENTAL HOSPITAL OF LONDON.—Surgeons: Messrs. Fox, Medwin, Gregson, Coleman, Moon, and Hill. Assistant Surgeons: Messrs. Hepburn, Gibbings, Woodhouse, Hutchinson, Ampton, and Bartlett. Dental House Surgeon: Mr. McCall. Assistant Dental House Surgeon: J. B. Major. Fee for two years' hospital practice, £15 15s.

NATIONAL DENTAL COLLEGE.

This is quite a modern institution having been open about two-and-a-half years. In connection with it is the National Dental hospital, situate in Great Portland Street, which was established in 1861. The teaching at this school is recognised by the Royal College of Surgeons for the dental diploma, and lectures and demonstrations are given similar to those at the London School of Dental Surgery in Leicester Square. The following are the lecturers with their subjects:—Dental anatomy and physiology: Mr. Thomas Gaddes. Dental surgery and pathology: Mr. Oakley Coles. Dental mechanics: Mr. G. J. Williams. Dental metallurgy: Mr. Alfred Tribe. Supplemental Lectures.—Operative dental surgery: W. F. Thompson. Elements of histology: Thomas Gaddes. Demonstrations on dental mechanics: Mr. Harry Roser Deformities of the mouth: Mr. Oakley Coles. The session commenecs on October 1st.

SCHOOL OF PHARMACY OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

Lectures are delivered on Monday, Tuesday, and Wednesday mornings at 9 o'clock. The course consists of sixty lectures. Two courses are given annually, the first commencing in October, and the second course in March, 1880. The subjects of these lectures are—(1) Physics in relation to chemistry and pharmacy. (2) Inorganic chemistry. (3) Organic chemistry, botany, and materia medica. These lectures are delivered on Thursday, Friday and Saturday mornings at 9 o'clock. The first course commences on October 4th; the second course on March 6th, 1880. The laboratories are open from ten o'clock in the morning until five in the afternoon daily, except on Saturdays, when they are closed at 2 o'clock. Fees for ten months, according to hours of attendance, twelve to twenty-five guineas; for shorter terms in proportion. Each student is expected to attend every lecture of the course for which he has entered, or to state the cause of absence to the professor or to an assistant.

SOUTH LONDON SCHOOL OF PHARMACY.

This school, which has accommodation for 120 students, is situated at Kennington Cross, and is decidedly the most popular institution for the study of practical pharmacy and chemistry in London. Instruction is also given in analytical chemistry for the purpose of qualifying gentlemen in search of appointments under the Public Health and Adulteration of Food Acts, by the principal, Dr. Muter. Lectures are delivered daily in the laboratory, and each student is required to practically illustrate that he grasps the subject taught as the lecturer proceeds. The winter session commences a fortnight earlier than the medical schools.

SCHOOL OF HOMŒOPATHY.

Homœopathy has now a recognised teaching school for students, which is situate in Great Ormond Street, where lectures and instructions according to homœopathic principles are given by duly qualified members of the medical profession, and where students who believe in the *similia similibus curantur* theory can be taught according to their bent. The winter session at this school opens on October 2nd.

SCHOOL OF ANATOMY AND PHYSIOLOGY.

This is established for private tuition, and is situate close to University College, at 16 Woburn Place, its principal being Mr. Thomas Cooke, senior assistant surgeon to the Westminster hospital, assisted by Demonstrators. The whole of the anatomy (on the dissected body), of physiology (with microscopical preparations and such experiments as the law permits), and operative surgery (on the dead body), are gone through carefully every three months. Fees: Three months, three guineas; six months, four guineas; for the higher examinations, with *special* supplementary class five guineas. There is a well-appointed dissecting room near the school.

NOTE.—*Where fuller information is required by the reader than that contained in the foregoing notes, it will generally be found on reference to our advertising columns, where also will be found the names of the staffs, lecturers, etc.*

HOURS OF THE INTRODUCTORY LECTURES

To be delivered on Wednesday Oct. 1, at the different Metropolitan Schools.

St. Bartholemew's Hospital—None.
Charing-Cross Hospital—Mr. Bird—4 p.m.
St. George's Hospital—Mr. Dalby—4 p.m.
Guy's Hospital—None.
King's College Hospital—Prof. Duffin—4 p.m.
London Hospital—None.
St. Mary's Hospital—Mr. St. George Mivart—3 p.m.
Middlesex Hospital—Dr. Coupland—3 p.m.
St. Thomas's Hospital—Dr. Cory—4 p.m.
University College—Prof. Thane—3 p.m.
Westminster Hospital—Dr. Dupré—3 p.m.

THE PRINCIPAL METROPOLITAN HOSPITALS TO WHICH NO MEDICAL SCHOOL IS ATTACHED.

Open to Students from the Larger Hospitals.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park.—This is a large and important hospital at the East End, containing 164 beds. Consulting Physicians: Drs. T. B. Peacock, J. Risdon Bennett, E. Lloyd Birkett, J. Andrew. Consulting Surgeon: Mr. Erichsen, F.R.S. Physicians: Drs. S. H. Ward, Eustace Smith, J. C. Thorowgood, Shepherd. Assistant Physicians: J. B. Berkart, S. W. Berkart, Fothergill, Heron, V. D. Harris, and J. A. Ormerod.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—This is the largest institution for the treatment of affections of the chest in the United Kingdom, and contains 192 beds. Consulting Physicians; Drs. C. J. B. Williams, W. H. Walshe, and R. Quain. Consulting Surgeon: Prof. John Marshall, F.R.S. Physicians: Drs. J. E. Pollock, E. S. Thompson, C. T. Williams, R. D. Powell, and J. Tatham. Assistant Physicians; Drs. R. Thompson, Burney Yeo, F. Roberts, T. H. Green, and J. M. Bruce. Dental Surgeon: Mr. W. P. Bartlett. Resident Medical Officer; Dr. W. T. Law. Secretary: Mr. H. Dobbin. Three clinical assistants reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital. Terms, £3 3s. for three months; perpetual £5 5s.

HOSPITAL FOR DISEASES OF THE THROAT AND CHEST, Golden Square, W.; contains 21 beds, outposts, Newington-butts, Walworth, and St. John's Gardens, Notting Hill.—Physicians: Drs. Morell Mackenzie, Robert H. Semple, Prosser James, W. McNeill Whistler. Surgeons: Dr. E. Woakes and Mr. W. R. H. Stewart. The practice of the hospital is open to students on payment; fee for three months' course three guineas; for six months five guineas; perpetual course seven guineas. Laryngoscopic demonstrations are given daily at half-past two.

CENTRAL LONDON THROAT HOSPITAL, Gray's-Inn Road.—25 beds. The staff consists of Mr. S. Jones, Consulting Surgeon, and Messrs. Lennox Browne and Llewelyn Thomas, Surgeons. Six clinical assistants, being either qualified practitioners or students of three years' standing, are elected to assist the surgeons. There are no fees.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road, E.C.—This hospital treats nearly 6,000 out-patients annually, and makes up 26 beds. A new wing, of which the foundation stone was laid by Princess Louise, will raise the number of beds to over 60. Consulting Physicians: Drs. Herbert Davies and Horace Dobell. Physicians: Drs. G. Goddard Rogers, P. J. Hensley, Gilbert Smith, and D. W. Finlay. Assistant Physicians: Drs. R. Wharry and W. Murrel. Consulting Surgeon: Mr. G. W. Callender. Surgeon: Mr. W. Walsham. House-Physician: Dr. Bland.

EAST LONDON HOSPITAL FOR CHILDREN.—Physicians: Drs. Eustace Smith, and Horatio B. Donkin. Assistant Physicians: Drs. Warner and Crocker. Surgeons: Messrs. A. Cæsar,, H. A. Reeves. Assistant Surgeon: Mr. R. W. Parker. House Surgeons: T. E. Hayward. Secretary: Mr. Ashton Warner.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, Queen's Square, W.C., and Cromwell House, Highgate.—Physicians: Drs. Dickinson, Gee, and W. B. Cheadle. Assistant Physicians: Drs. R. J. Lee, C. Sturges, Thomas Barlow, D. B. Lees, and Robert Bridges. Surgeons: Mr. T. Smith, Mr. F. Howard Marsh, Mr. Edward Owen, and Mr. J. H. Morgan. Surgeon-Dentist: Mr. A. Cartwright. Fee for three months' attendance, £3 £3; perpetual, £5 5s. Secretary; S. Whitford. There are now 104 beds in the hospital, Great Ormond Street, and 52 beds in the country branch; total, 156. The practice at the hospital has recently been thrown open gratuitously to the pupils of the different hospitals and medical schools of London, on conditions which may be ascertained of the Secretary.

THE HOSPITAL FOR WOMEN, Soho Square, W.—Physicians: Protheroe Smith, Heywood Smith, C. H. Carter. Surgeon; H. A. Reeves. Assistant Physicians: R. T. Smith, E. Holland, Mansell Moullin. Chloroformist: T. Bird. The hospital contains 61 beds. Clinical instruction is regularly given in the wards, and in the out-patient room daily at 10. Clinical clerks and assistants are appointed from time to time, application to be made to the physicians. Students received after the third year.

BRITISH LYING-IN HOSPITAL, Endell Street, St. Giles's, W.C.—25 beds. Consulting Physician: Dr. Priestly. Consulting Surgeon: T. Spencer Wells, F.R.C.S. Physicians: Drs. Heywood Smith, Arthur Edis, and S. Fancourt Barnes. This institution receives women only as midwifery pupils. The fee for the course of three months is £10 10s. Pupils who prove themselves competent receive a certificate signed by the physicians, enabling them to practise midwifery.

THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN, Lower Seymour Street.—52 beds. Physicians: C. H. F. Routh, W. R. Rogers, W. H. Day, Wynn Williams, P. Boulton, and F. H. Champneys. Surgeons: G. C. Bantock, J. K. Thornton, A. H. G. Doran, and W. A. Meredith.

ROYAL LONDON OPHTHALMIC HOSPITAL, Bloomfield Street, Moorfields, is the largest of its class in the metropolis, and contains 100 beds. Consulting Physician: Dr. F. J. Farre. Consulting Surgeons: Messrs J. Dixon, G. Critchett, W. Bowman, F.R.S., and J. Hutchinson. Surgeons: Messrs. Wordsworth, Streatfield, Hulke, Lawson, Couper, and J. Soelberg Wells. Assistant Surgeons: W. Tay, J. E. Adams, J. Tweedy. House Surgeon: Mr. Gunn. Number of patients annually, about 20,000.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William Street, Charing Cross.—The hospital contains 50 beds. The practice of the hospital is open to students. Fees for six months, £3 3s.; perpetual, £5 5s. Students of the hospital are eligible for the post of house-surgeon.

LONDON FEVER HOSPITAL, Islington.—260 beds. Consulting Physician: Dr. Tweedie. Physicians: Drs. Broadbent and Cayley. Assistant Physician: Dr. Mahon. Consulting Surgeon: Mr. W. S. Savory. Resident Medical Officer: Mr. H. F. Harvey.

ST. PETER'S HOSPITAL FOR STONE AND URINARY DISEASES, 54 Berners Street, Oxford Street.—Surgeons: Walter J. Coulson, W. F. Teevan. Assistant Surgeon: F. R. Heycock. Resident Medical Officer: A. S. Semon. Medical men and students are admitted to the practice of the hospital gratis. It contains 16 beds, and 138 in-patients were treated during the past year. The number of out-patients was 13,058, of whom 1,696 were new cases.

GREAT NORTHERN HOSPITAL, Caledonian Road.—Physicians: Drs. Leared, Cholmeley, Crucknell, Cooke, Bridges. Obstetric Physician: Dr. Gustavus C. P. Murray. Consulting Surgeons: Mr. F. Le Gros Clark, F.R.S. Surgeons: Messrs. Gay, W. Adams, W. Spencer Watson, W. H. Cripps, and J. Macready. Ophthalmic Surgeon: Dr. R. W. Lyall. Aural Surgeon: Mr. A. E. Cumberbatch. Dental Surgeon: Mr. C. J. Fox. Chloroformist: Mr. Eastes. House Surgeon: Mr. T. H. Gillam.

WEST LONDON HOSPITAL.—A well appointed hospital at the western extremity of the metropolis in the Hammersmith Road, containing 60 beds. Consulting Physician: Dr. Maudsley, Consulting Physician-Accoucheur: Dr. W. O. Priestley. Consulting Surgeons; Messrs. S. A. Lane and William Bird. Physicians: Drs. Goddard, Rogers, and Thorowgood. Physician for Diseases of Women: Dr Wiltshire. Surgeons: Messrs. W. F. Teevan and Alfred Cooper. Ophthalmic Surgeon: Mr. B. J. Vernon, Assistant Physicans: Drs. Fish, Fothergill, Vincent Harris. Assistant Surgeons: Messrs. H. T. Butlin. Keetley, and Otley. Surgeon-Dentist: Mr. Smale. Resident Medical Officers: Two House Surgeons, and an Apothecary. Gentlemen desirous of acting as clinical clerks or dressers can obtain all information by application to Mr. T. Alexander, at the hospital. The practice of this hospital is open to all students and practitioners.

BETHLEM HOSPITAL.—This hospital is open for the admission of two resident medical students, who have recently obtained their diplomas to practise Medicine and Surgery, for the acquisition of knowledge regarding the Insane. The next election takes place in October, at Bridewell Hospital, and the elected candidates will be expected to commence residence on the 1st of November.

ROYAL FREE HOSPITAL, Gray's Inn Road.—This hospital contains 150 beds. Of the smaller metropolitan hospitals few offer a more extensive field for students in medicine and surgery. An arrangement has been made by which medical students from the School of Medicine for Women are enabled to attend their hospital courses at this institution. Physicians: Drs. Hassall, O'Connell, and Cockle. Surgeons: Messrs. J. Gant, and W. Rose. Secretary: Mr. J. S. Blyth, from whom full particulars of the dresserships and clerkships may be obtained. Assistant Surgeon: Mr. W. H. Cripps. House Surgeon: Mr. R. Atkinson.

THE TEMPERANCE HOSPITAL.—The character of this institution is fully described by its title, and the non-alcoholic treatment is carried out in its entirety by an efficient staff. It is situated close to the University College in Gower Street.

SEAMEN'S HOSPITAL (late *Dreadnought*), Greenwich.—300 beds. For the reception of seamen of all nations who are received at all hours. Apartments are provided in the house of the surgeon for students and others who may be desirous of studying diseases incidental to tropical climates before entering the services or going abroad. Honorary Consulting Physicians: Drs. George Budd and Stephen H. Ward. Visiting Physicians: Dr. Charles Henry Ralfe and Mr. Harry Leach. Honorary Consulting Surgeon: Mr. Geo. Busk. Visiting Surgeon; Mr. N. Davies-Colley. Surgeon: Mr. W. Johnson Smith. House-Physician: Dr. de Fonmartin. House-Surgeon: Mr. P. Dunn. Secretary: Mr. Henry C. Burdett.

ENGLISH PROVINCIAL MEDICAL SCHOOL.

BIRMINGHAM: QUEEN'S COLLEGE.—Students are admitted—(1) as matriculated students who enter for their entire medical educa-

Digitized by Google

tion; (2) as occasional students for one or more courses of lectures; (3) as junior students, to prepare for the preliminary examinations of the licensing boards.

Scholarships, Prizes, &c.—The Sands Cox prize, value £20. Open to students who have completed their curriculum. Subjects:—Medicine, Surgery, and Midwifery. Two Ingleby scholarships for obstetric medicine and surgery and diseases of women. The Warden's prize, value £5 5s., for first year's students, for general proficiency. The Percy prize, value £5 5s., for German.

Fees.—College fees for all lectures amount to 60 guineas, payable by two equal instalments.

Hospital practice is obtained at the General and Queen's Hospitals, which have been amalgamated for the purpose of clinical instruction under the direction of the Birmingham Clinical Board by whose order all schedules are signed and all examinations conducted. The hospitals have a total of upwards of 400 beds, and the staff attached is of a very high order.

All students will be required to attend six months alternately at each hospital, as directed by the Clinical Board, excepting students who enter the hospital for six months only.

Clinical Prizes.—The following prizes are given annually:—Senior medical prize for third and fourth year's students, first prize £5 5s.; second prize £3 3s. Senior surgical prize, for third and fourth year's students, first prize £5 5s., second prize £3 3s. Junior medical prize, for second year's students, first prize £3 3s. second prize £2 2s. Junior surgical prize for second year's students, first prize £3 3s., second prize £2 2s. Midwifery prize £4. Medals and certificates are awarded in each class. The examinations for all the appointments and prizes are conducted by the Clinical Board, and are open for competition to all students registered by the Clinical Board.

Fees for attendance for four years on the medical and surgical practice, and on the clinical lectures at both hospitals, £42.

BRISTOL SCHOOL OF MEDICINE (University College).—Attached to this school, where there is ample provision for education and practice, are two well-appointed hospitals, the Royal Infirmary containing 264 beds, and the General Hospital, with 154 beds. Competitive examinations are held amongst students of the first, second, and third years respectively, and prizes of money, instruments and books are awarded annually. The certificates of this school are accepted by all the examining boards. Medical and surgical hospital practice and clinical lectures are attended at the Royal Infirmary or at the General Hospital, at which institutions additional prizes are annually offered for competition amongst the students. The existing medical school forms a department of the College of Science and Literature.

Scholarships, Prizes, &c.—Prizes and certificates of honour are given in the medical school to first, second, and third year's students, and also in practical anatomy. At the Royal Infirmary.—Suple's medical prize, a gold medal and £7 7s.; Suple's surgical prize, as the medical; Clark prize (interest of £500) for third year's student; pathological prize, value £3 3s. At the General Hospital.—Martyn memorial scholarship, £20; Clarke scholarship (surgical), £15. Sander's scholarship (interest of £500), medicine and surgery; Lady Haberfield's prize (£1,000), for general proficiency.

Clinical lectures are given at both institutions, three and four times a week.

Fees.—School fees for unlimited attendance on all courses of lectures except comparative anatomy, 60 guineas.

LEEDS SCHOOL OF MEDICINE.—Clinical lectures are given by the physicians and surgeons attached to the General Infirmary. Ophthalmic demonstrations and demonstrations of skin diseases are given in the Infirmary by the surgeons in each department, where also are obtainable six clinical clerkships and eight dresserships Besides the Infirmary there is a large Dispensary and a fever hospital, both of which are open to students of the school. Students at this school have excellent opportunities of acquiring a thorough insight of psychological medicine, as the renowned West Riding Lunatic Asylum is in connection, and Dr. Major lectures on mental diseases. The systematic lectures are given at the school, and the clinical lectures at the asylum, which now accommodates 1,500 patients.

There is the Hardwicke scholarship in clinical medicine, value £10, the Thorp, in forensic medicine, value £10; three surgeons' clinical prizes, of £8, £5, and £3 respectively. Silver and bronze medals, books, and certificates of honour are awarded for proficiency in particular subjects.

The composition fee for attendance upon all the required courses of school lectures is £50 8s., to be paid on entrance; or £26 5s. on entrance, and a second sum of £26 5s. twelve months afterwards.

At the General Infirmary the perpetual fee for medical practice and clinical lectures is £26 5s. The same amount is charged for the perpetual attendance on the surgical practice and clinical lectures. These fees are not included in the composition fees for lectures, and are payable separately.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.—The infirmary attached to this school, which contains 300 beds, with 40 special wards for the treatment of diseases of women, is perhaps second to none in England in its general appointments, and the facilities it offers to students for gaining practical knowledge.

A payment of 50 guineas on entrance, or in two equal instalments (one-half on entrance, and the remainder within twelve months), entitles the student to attendance on all the necessary lectures and demonstrations. The Royal Infirmary contains nearly 300 beds. There are special wards for the treatment of uterine and other diseases of women. During the year 1878 2,700 patients were admitted into the infirmary; the number of out-patients was 5,300. The Lock Hospital adjoining the infirmary contains 60 beds; during the past year 598 males and females were admitted as in-patients, the daily average number in the house being 41.

Two house-physicianships and three house-surgeonships, tenable for six months, and open to pupils of the school who have obtained a legal qualification; clinical clerks and dressers: post-mortem clerks.

Two Roger Lyon Jones scholarships, each of £21, for two years, one awarded as an entrance scholarship, and the other being open to students who have completed their second year; the Torr gold medal for anatomy and physiology; the Bligh gold medal for anatomy and physiology. School medals and certificates of honour are awarded for proficiency in certain groups of subjects.

The fee for a perpetual ticket for hospital practice is £33 12s., and may be paid in two equal instalments (one-half on entrance, and the remainder within twelve months).

MANCHESTER: OWENS COLLEGE SCHOOL OF MEDICINE.—This school, as most of our readers are aware, has resulted from the amalgamation of the Manchester Royal Infirmary School of Medicine with the Owens College, and occupies in the provinces a somewhat similar position to that of University College and Hospital in London. It has a Faculty of science as well as of medicine, with departments of laws and arts. Since the amalgamation a new medical school has been built, on the most approved principles, at the western extremity of the college estate. On the ground-floor are two large lecture theatres, a library, and a museum. Over the lecture theatres is a dissecting-room, and over the library a physiological laboratory. The course of instruction afforded to students is thoroughly complete. Three of the most important chairs—those of anatomy, physiology, and chemistry—are held by professors who entirely devote their time to the work of instruction. Students wishing to engage in physiological or pathological researches will find opportunities for study in the complete and well-furnished physiological laboratory. Two valuable physiological scholarships are placed for competition in this branch as an incentive to original research.

Appointments.—Resident medical officer £250 per annum; resident medical officer at Cheadle, £150; resident medical officer at Monsall, £200; resident surgical officer, £150; eight house-surgeons, six months each; four house-physicians for six months each; a registrar; a pathological registrar, £100 each.

Scholarships, Prizes, &c.—Turner scholarship £25, for third year's men; Platt physiological scholarship, two, £50 each, five years; one annually for physiology. Platt exhibitions: Details of these will be forwarded early in the session on application. Dumville surgical prize, £20: examination takes place April 29 and 30, 1880. Prizes of books, instruments, &c., varying from £5 5s. to £3 3s., for third, second, and first year's students. Entrance scholarships.—Dauntesey medical scholarship: candidates not to be over 25 years of age; may be registered, but must not have studied at any medical school; value (about) £100, for one year; successful candidates must at once enter on full medical course in the Owens College. Examination commences October 1st, 1879. Subjects—General and comparative anatomy, physiological botany, chemistry, including practical work, and either mathematics or Latin. Gilchrist scholarships:—Three of £50 for three years. One is annually awarded to candidates standing highest at matriculation of London University in June (provided he be in the honours division); failing such, two of £25 to the two candidates standing highest in the first division; candidates must be between 16 and 20 years of age. There are also grammar school scholarships.

Fees.—Composition fee £63, or two sums of £31 10s. each. Hospital practice: composition fee £42, or two instalments of £22 each. Further information may be obtained of Professor Gamgee, Dean of the School, or of the Registrar, M. J. Holme Nicholson, Owens College, Manchester.

NEWCASTLE-ON-TYNE COLLEGE OF MEDICINE.—This school is a department of the University of Durham, and contains ample provision for acquiring a sound education and practical experience at the bedside. It is smaller than some of the provincial schools, but with some parents and students this would be considered an advantage.

Hospital practice is obtained at the Newcastle Infirmary, which has 230 beds, and in which the required clinical lectures are delivered.

Fuller information of this college will be found under the heading University of Durham.

SHEFFIELD SCHOOL OF MEDICINE.—Students at this College obtain excellent instruction in medical and surgical practice at the General Infirmary, which contains 180 beds, and is provided with a museum and pathological and post-mortem theatres. The fees for perpe-

Digitized by Google

tual attendance are £15 15s. for medical and £21 for surgical practice; for twelve months medical and surgical practice, each £10 10s.; and for six months £6 6s. each. There is also the Sheffield Hospital and Dispensary, containing 104 beds, and is recognised by the College of Surgeons and the Hospital for Diseases of Women, to which students are admitted. The perpetual fee for attendance on all the lectures required by the Royal College of Surgeons and the Apothecaries' Hall, £42. Prizes to the value of £30 and certificates of honour are given annually. Some of the lecturers, and other local members of the profession, receive house pupils, which will be found far preferable to life in ordinary lodgings.

LIVERPOOL ROYAL SOUTHERN HOSPITAL.—This Institution is one of the largest in the English provinces, and contains 200 beds. It has no school proper, although it contains accommodation for resident pupils, and clinical lectures are delivered daily by members of the staff. These, together with the practice obtained here, which is of a very varied and valuable character, is recognised by all the examining boards. Inclusive fees—perpetual, 25 guineas; one year, 10 guineas; six months, 7 guineas; three months, 4 guineas. Students can enter to the medical or surgical practice separately on payment of half the above fees.

NOTE.—*Our advertising columns, of which an index will be found at the end of the editorial matter, will supply further information, with the names of staff, &c., attached to the foregoing schools.*

REGULATIONS AND BYE-LAWS OF LICENSING BODIES IN IRELAND.

UNIVERSITY OF DUBLIN.

(*For Names of Professors and Examiners see Advertisements.*)

THE Board of Trinity College, acting under the advice of their distinguished late Medical Registrar, now chairman of the committee of the Medical School, Professor Haughton, has steadily pursued a course which has raised the medical degrees of the University of Dublin to the highest rank—we might almost say—amongst the licensing authorities of the three kingdoms, and which merits the warm acknowledgments of all friends of priority of medical education.

REGULATIONS OF THE SCHOOL OF PHYSIC.

Matriculation.

Every student must be matriculated by the Senior Lecturer, for which a fee of 5s. is payable; but he need not attend any of the Arts courses unless he desire to obtain a licence or degree in medicine or surgery. No student can matriculate unless he has passed the Entrance Examination in Trinity College, in the Royal College of Surgeons of Ireland, or some other examination recognised by the General Medical Council. No student can be admitted for the Winter Courses after the 25th November.

QUALIFICATIONS FOR DEGREES AND LICENSES.

Bachelor in Medicine.

Candidates must be graduates in Arts, and may obtain the degrees at the same commencement as the B.A., or at any subsequent one. The medical education of a Bachelor in Medicine is of four years' duration, and comprises the following lectures:—

Winter Courses.—Anatomy and physiology; practical anatomy; surgery; chemistry; practice of medicine; midwifery; practical histology.

Summer Courses.—Botany; materia medica and pharmacy; institutes of medicine; medical jurisprudence and comparative anatomy; heat, electricity, and magnetism.

Hospital attendance on a medico-chirurgical hospital during three courses of nine months each, with clinical lectures, including actual attendance on fever; six months' practical midwifery. Six months' dissections and three months' laboratory instruction in chemistry are required.

The Courses may be attended at any recognised medical school.

The fee for the *Liceat ad Examinandum* is £5.

The fee for the degree of M.B. is £11.

Doctor in Medicine.

A Doctor in Medicine must be M.B., or qualified to take that degree, for three years. He must also read a thesis before the Regius Professor of Physic.

Total fee for this degree, £13.

Bachelor in Surgery

must be a B.A., have spent four years in the study of surgery and anatomy, and passed the M.B. examination.

The curriculum comprises the following, in addition to the course for the M.B.:—

Theoretical and operative surgery ...	One course.
Dissection	Two courses.
Ophthalmic surgery	One course.

Candidates are required to perform operations on the dead subject.

Candidates for the B.Ch. who have already passed the M.B. will be examined in anatomy and surgery only.

Fee for the *Liceat ad Examinandum*, £5.

Fee for the degree of Bachelor in Surgery, £5.

Master in Surgery

must be a B.Ch. of three years' standing, and must read a thesis.

Fee for the degree of Master in Surgery, £11.

Master in Obstetric Science

(a Degree lately founded by order of the Board of T.C.D.).

A Master in Obstetric Science must have passed the M.B. and B.Ch. Examinations, and produce certificates of having completed the following curriculum:—

1. One Winter course in midwifery.
2. Six months' practice in a recognised lying-in hospital or maternity.
3. A Summer course in obstetric medicine and surgery.
4. Two months' practice in the Cow-pock Institution.

Graduates of medicine of M.D. standing may present themselves for examination without complying with Regulations 3 and 4.

Fee for the degree of M.A.O., £5.

UNIVERSITY LICENCES.

Candidates for the licences in medicine or surgery must be matriculated in medicine, and must have completed *two years in Arts.*

Licentiate in Medicine.

The course and examination are the same as for the M.B.

An L.M. on proceeding to the degree of B.A. may become an M.B. on paying the fees without further examination.

Fee for the *Liceat ad Examinandum*, £5.

Fee for the licence in medicine, £5.

Licentiate in Surgery.

The course and examination necessary for the Licence in surgery is the same as for the degree of Bachelor in surgery.

Fee for the *Liceat ad Examinandum*, £5.

Fee for the licence in surgery, £5.

MEDICAL SCHOLARSHIPS.

Two Medical Scholarships are given annually, value £20 per annum each, tenable for two years, the examinations for which are held each year in June, in the following subjects:—Anatomy and physiology, chemistry, materia medica, botany, experimental physics, and comparative anatomy.

Medical Schools Exhibitions.

The Professors of the University school give three Exhibitions annually, two senior, value £15 and £10, open to all students who have been three years attending the school, the subjects being—Practice of medicine, surgery, pathology, and forensic medicine; one junior, value £15, the time and subjects of examination being the same as those for the Medical Scholarship.

The board of Trinity College have recently passed orders—1. That three-fourths of the lectures must be attended. 2. that a daily roll be called by by each Professor.

Students entering for demonstrations and dissections are required to pay £8 8s. before November 25; dissections only, £5 5s.; demonstrations only, £3 3s.; fourth year's dissections, £2 2s.

QUEEN'S UNIVERSITY IN IRELAND.

FACULTY OF MEDICINE.

BY virtue of the Irish University Act of last session, the Queen's University has ceased to exist, and is merged in the new National University of Ireland. Its last examinations were held during the past week, and no degrees will in future be granted by the "Q.U.I." The regulations hitherto published in our Students' Number are therefore obsolete, and as those of the new University are not extant, we are unable to give them. The Queen's Colleges maintain their existence as affiliated Colleges of the new University, and we therefore give the needful information concerning them in another column. Communications respect-

Digitized by Google

ing the Queen's University should be addressed to G. I. Stoney, Esq., F.R.S., Dublin Castle.

A detail of the prizes and exhibitions in arts and medicine, the names of the professors, and other information, *will be found in the Advertisemenets* of this issue, and full details may be had on application to—

Belfast.—John Purser, M.A., Registrar.

Cork.—Alexander Jack, M.A.

Galway.—Arthur Hill Curtis, M.A., LL.D.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

LETTERS TESTIMONIAL, OR THE L.R.C.S.I.

The examination is divided into two parts, known as the first and second halves.

The junior class must produce certificates of—

a, Preliminary examination, including Greek; *b*, three courses of lectures on anatomy and physiology; *c*, three on practical anatomy, with dissections; *d*, two on chemistry; *e*, one on materia medica; *f*, one on botany; and *g*, one on forensic medicine. This class is examined in anatomy, histology, physiology, materia medica, and chemistry.

The senior class must produce certificates of—

a, Three courses on surgery; *b*, one on practice of medicine; and *c*, one on midwifery; also attendance on a recognised hospital for three winter and three summer sessions. This class is examined in surgery, operative surgery and appliances, practice of medicine, medical jurisprudence, and prescriptions.

The fees are: £5 5s. as registered pupil of the College; £5 5s. for the Junior Class Examination, which is not returned in case of rejection, but is allowed in the fee for his second examination; £15 15s. for the Senior Class Examination—total £26 15s.

Pupils *who neglect registering themselves previous to going in for the preliminary examination*, must pay £1 1s. for that examination, to which, however, registered pupils, in addition to their other privileges, are free.

Every candidate rejected at the quarterly examination is required to pay to the College the sum of £2 2s. on applying for re-examination.

Method of Examination.—Candidates must lodge their fees and certificates one week before the day.

JUNIOR CLASS.—The candidates are examined in alphabetical order, and the examination occupies three days: 1st day, dissections; 2nd day, written examination on anatomy, physiology, histology, materia medica, and chemistry; 3rd day, *vivâ voce* examination on the same subject. No candidate can proceed to the second day who has not passed the first; or to the third, who has not passed the second.

SENIOR CLASS.—The examination occupies four days: 1st day, written examination on surgery, practice of medicine, medical jurisprudence, and prescriptions; 2nd day, *viva voce* examination on surgery and practice of medicine; 3rd day, clinical examination; 4th day, operative surgery.

No candidate can present himself for examination after the first day who has not satisfied his examiners upon the previous day; but all candidates who have passed any day's examination get credit for same. When presenting themselves upon a subsequent occasion, a former candidate is only required to present himself upon that portion of the examination in which he has failed.

Midwifery.—After passing the L.R.C.S., the student is admitted to examination for diploma in Midwifery upon producing a certificate of one course on Midwifery and Diseases of Women and Children; a certificate that he has attended a lying-in-hospital for six months; and a certificate that he has conducted thirty labour cases at least.

Candidates are examined on the Organisation of the Female, the Growth and Peculiarities of the Fœtus, the Practice of Midwifery, and the Diseases of Women and Children.

The candidate pays £1 6s. for the Midwifery diploma, provided he takes it out within one month from the date of his Letters Testimonial; after that date, £2 2s.

Official information may be had on application to Mr. J. Brennen, Royal College of Surgeons, Dublin.

DENTAL REGULATIONS.—During the past year the Council has under the authority of the Dentists Act created a new license in dental surgery. The examiners shall consist of three [illegible] of the College, three registered dentists, and the vice-president, or other member of the Council of [illegible] (summoned in rotation).

The board has the absolute power to refuse the application of any candidate.

The examinations, up to the first day of August, 1881, shall be of a practical character, embracing the anatomy, physiology, surgery, and pathology of the teeth, jaws, and surrounding parts, and mechanical dentistry; and shall be partly written and partly oral.

All candidates shall lodge at least one fortnight previous to each examination.

I.—A certificate of having attained the age of 21 years.

II.—Certificates from two fellows or licentiates of any College of Surgeons in the United Kingdom, and from two dentists of repute, testifying that the candidate is of good character, has been engaged in the practice of dentistry for at least five years, and has refrained from advertising or other unbecoming modes of attracting business for at least two years previously.

III.—Receipt for the fee of ten guineas.

After the 1st day of August, 1881, no candidate shall be admitted to examination who has not pursued the following curriculum, and lodged with the registrar of the College, at least a fortnight previous to examination.

I.—A certificate of having attained the age of 21 years.

II.—A certificate of having been engaged during four years in the acquirement of professional knowledge.

III.—Certificates of character as above.

IV.—A certificate of having passed the examination in preliminary education.

V.—A receipt for the fee of ten guineas.

VI.—Certificates of having attended in a recognised school—one course of lectures on anatomy and physiology, two courses of dissections, with demonstrations, one course of lectures on surgery, one course of lectures on chemistry, one course of practical chemistry and metallurgy, one course of lectures on materia medica, and two courses of lectures on dental surgery, including dental mechanics.

VII.—Certificates of having attended general hospital practice for two winter sessions; and the dental department of a general hospital, or a special dental hospital, for a further period of nine months.

VIII.—A certificate of having been engaged during, at least three years, in acquiring a practical knowledge of dentistry, under the instruction of a registered licentiate in dentistry of one of the licensing bodies.

The examinations shall include all the subjects of the foregoing curriculum, and shall be partly written and partly oral, preparations, microscopes, and other appliances being used.

N.B.—Every successful candidate, previous to receiving the license, shall declare that he will not advertise or pursue any other unbecoming mode of attracting business, so long as he holds the license in dentistry of the College.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

REGULATIONS RESPECTING LICENSES IN MEDICINE AND MIDWIFERY.

I.—EXAMINATIONS for the licenses of the college in medicine and midwifery are held in the week following the first Friday in each month, except August and September.

II.—Every candidate for either license must return his name to the registrar, and lodge his certificate, bank receipt of fees, and his schedule, (*a*) at least *four* days before the first Friday in each month.

THE LICENSE IN MEDICINE.

Every candidate is required to produce satisfactory evidence:—

1. Of character, from a Fellow of the College, or from two registered practitioners.

2. Of having passed an examination in general education, held by some of the recognised examining bodies.

3. Of having been engaged four years in the study of medicine.

4. Of having attended lectures on the following subjects, at recognised schools.

Practical Anatomy, two courses. Physiology or Institutes of Medicine, one course. Chemistry, one course. Practical Chemistry, one course. Materia Medica, one course. Medical Jurisprudence, one course. Practice of Medicine and Pathology, one course. Surgery, one course. Midwifery, one course.

5. Of twenty-seven months, at a Medico-Chirurgical Hos-

Digitized by Google

pital, in which clinical lectures and clinical instruction in medicine are given; and of nine months of a clinical hospital which contains wards for the treatment of the infectious fevers (*b*)—said nine months being included in the total period of twenty-seven months

6. Of having attended practical midwifery and diseases of women for six months at a recognised Lying-in Hospital, or Maternity; or, where such hospital attendance cannot have been obtained during any period of the student's course of study, of having been engaged in practical midwifery under the supervision of a registered practitioner holding public appointments; not less than twenty labour cases to be actually attended.

III.—The professional examination is divided into two parts:—

First Part.—Anatomy, Physiology, Chemistry, and Materia Medica.

Second Part.—Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics.

IV.—Any registered practitioner of *five* years' standing shall be admitted to examination for the license of the College, on producing his certificate of registration, with satisfactory reference, and shall have the privilege of being exempted from the examination by printed questions.

Each candidate shall be examined separately, and shall be required to recognise pathological specimens, and undergo such other practical tests as the examiners shall select.

THE LICENSE IN MIDWIFERY.

Candidates for the license in midwifery, who are not licentiates in medicine, may be admitted to examination on the following qualifications:—

(1) The degree or license from any University or College in the United Kingdom; (2) Testimonials as to character; (3) Certificates of having attended (*a*) a course of lectures on midwifery in a school, recognised by the College (see Rule III). (*b*) Practical midwifery and diseases of women, for six months, at a Lying-in Hospital, or Maternity recognised by the College; or where such hospital attendance cannot have been obtained during any period of the candidate's course of study, of having been engaged in practical midwifery under the supervision of a registered practitioner holding a public medical appointment,—the certificate, in either case, to state that not less than twenty labour cases have been actually attended.

Candidates who are already licentiates in medicine of the College, or who have passed the examination for such license, may be admitted to examination for the license in midwifery on lodging their fees, and signifying their wish to the registrar a week at least before such examination.

X.—Any registered practititioner of *five* years' standing shall be admitted to examination for the license in midwifery, on producing his certificate of registration, with satisfactory reference; and he shall have the privilege of being exempeed from the examination by printed questions.

FEES FOR LICENSE AND EXAMINATIONS.

XI.—License in medicine, fifteen guineas, which may be divided as follows, viz.:—

For examination at the termination of the first period of study, five guineas.

For final examination for the license, ten guineas.

XII.—License in midwifery, three guineas.

XIII.—Fee for examination, of the licenses in medicine and midwifery, if obtained within the interval of a month, sixteen guineas—to be lodged in one sum. (*a*)

XIV.—Fee for special examination for the license in medicine, twenty guineas.

XV.—Fee for special examination for the license in midwifery, five guineas.

XVI.—Fee for examination for the license to practice as a midwife and nurse-tender, one guinea.

THE APOTHECARIES HALL, IRELAND.

THE ARTS EXAMINATIONS.

Will be held at the Hall four times in the year—viz., the third Thursday in the months of January, April, July, and October, at the hour of twelve o'clock, noon.

The examination for *the License* is divided into two parts:—

The First Part comprehends Chemistry, Botany, Anatomy, Physiology, Materia Medica, and Pharmacy.

The Second—Medicine, Surgery, Pathology, Therapeutics, Midwifery, Forensic Medicine, and Hygiene.

THE PROFESSIONAL EXAMINATIONS

Will be held *quarterly*, on the first and second Monday in January, April, July, and October.

The First Part on the first Monday, at twelve o'clock, noon, and on the Tuesday and Wednesday succeeding at the same hour.

Subjects.—Chemistry and Botany, Monday; Anatomy and Physiology, Tuesday; Materia Medica and Pharmacy, Wednesday.

The Second Part, or Pass Examination, on the second Monday, at twelve o'clock noon, and on the Tuesday and Wednesday succeeding at the same hour.

Subjects.—Medicine and Surgery, Monday; Midwifery and Diseases of Women and Children, Tuesday, Forensic Medicine and Hygiene, Wednesday; Clinical Examination, Thursday.

The first two hours of each day will be devoted to writing answers, and after that, two hours to an oral and practical examination.

Candidates at the examination on Anatomy are liable to be called on to perform *dissections*; and at the examination on Surgery to perform one or more *operations* on the dead subject.

Doctors of Medicine and Licentiates of a College of Physians who have also spent twelve months at *Practical* Pharmacy, may obtain the License by undergoing an examination—the former in Pharmacy and the latter in Medicine and Pharmacy. Licentiates of the London Society of Apothecaries are admitted *ad eundem*.

THE PHARMACEUTICAL SOCIETY OF IRELAND.

THE above Society was instiuted by the Pharmacy Act (Ireland), in 1875, 38 & 39 Vict., cap. 57. In that Act it is stated that whereas a great deficiency existed throughout Ireland, of establishments for the sale of medicines and compounding of prescriptions, and that great inconvenience therefore arises to the public, it is expedient to amend the Act of 1791 (the Apothecaries Act). A president (Sir Dominic Corrigan) and vice-president (Dr. Aquilla Smith), with a council of twenty-one men, were named by the Government to carry out the provisions of the Act. In 1878 Sir Dominic Corrigan resigned the presidentship. The present president is Professor Tichborne, and the vice-president Dr. Aquilla Smith. The pharmaceutical chemist is not allowed to prescribe, but must strictly confine himself to the compounding of prescriptions. In this respect he differs from the apothecary. All persons who keep open shops for compounding of prescriptions must hold the license of the Pharmaceutical Society or the Apothecaries' Hall. The Society, according to their Calendar, which was corrected to the 21st December, 1878, had 154 licentiates. They hold evening meetings during the winter for the reading and discussing of pharmaceutical papers and scientific papers bearing on pharmacy. This Society has power under their Act to prosecute persons illegally compounding.

MEDICAL SCHOOLS AND HOSPITALS IN DUBLIN.

THE Clinical Hospitals of Dublin are 10in number, exclusive of the Cork Street Fever Hospital, 2 Lying-in Hospitals, 2 Ophthalmic Hospital, the Children's Hospital in Pitt Street, and other special institutions. To some of the Clinical Hospitals Medical Schools are attached; others, though they have no actual or official connection with any school, are in close affinity with certain teaching bodies, while others again are without any special connection with any school. While, however, such affiliation of a school and hospital may exist, it should be remembered that the Dublin schools and hospitals are open to all comers, and the student is competent to attend any hospital and any school he wishes.

The Names of the Professors, Lecturers, and Hospital Staff of the following Hospitals and Schools are not included in this column, being found in the advertisement of each institution.

SCHOOL OF PHYSIC AND SIR PATRICK DUN'S HOSPITAL.—The Medical School of Trinity College is one of the largest and most important. It is especially frequented by those students who intend to take the Arts Curriculum of the University, but is freely open to, and largely availed of by

Digitized by Google

other students. It is under the immediate supervision of a Committee of Professors with Rev. Prof. Haughton as Chairman, and the names of its Professors will be found appended to the advertisement in our journal. Two Medical Scholars are elected annually by the Board of Trinity College, at an examination held at the end of June. Each scholarship is worth £20 per annum, and is tenable for two years. The Professors of the School of Physic give three exhibitions annually, amounting altogether in value to £40, subject to conditions prescribed by the Professors themselves.

Sir Patrick Dun's is the hospital attached by Act of Parliament to the School of Physic, and officered by the Professors of that school. It was for many years a purely medical hospital, but is now a large medico-chirurgical hospital, with a Midwifery Maternity attached.

The ROYAL COLLEGE OF SURGEONS SCHOOL is situated within the walls of the College, and is under the superintendence of the Council, who appoint the Professors. The Professor of Physiology commences his course with a series of twelve lectures on Comparative Anatomy. The dissecting-rooms have recently been much enlarged, and are lighted with gas for evening work.

The CITY OF DUBLIN HOSPITAL has been hitherto more closely connected with the College School than any other hospital. It is situated in Upper Baggot Street, about ten minutes' walk from the Royal College of Surgeons. The hospital contains 130 beds, and accommodates about 1,300 intern patients annually. There are special wards for ophthalmic and aural diseases (on which subjects a special course of lectures is delivered), and for diseases of children. A new wing has been lately opened for the reception of fever and other infectious diseases. The "Purser" Studentship of £30 per annum (with apartments) is obtainable by competitive examination by all students; numerous prizes and medals are given, and special certificates are granted.

The CATHOLIC UNIVERSITY SCHOOL is situated in Cecilia Street, about ten minutes' walk from the University itself in St. Stephen's Green. Most of its Professors are physicians and surgeons of the Mater Misericordiæ, St. Vincent's, or Jervis Street Hospitals, and its courses of study qualify for admission to all the licensing bodies. The University grants an Exhibition of £20, a gold medal, value £7, and class prizes. There is no residence for students.

ST. VINCENT'S HOSPITAL was established in 1834 by the Sisters of Charity, some of whom had studied the system of the Parisian Hospitals, after which it was modelled. The ward for "*Enfans Malades*" is an interesting feature. The hospital has over 100 beds constantly full, and each sister has charge of about twelve patients. In connection with it is the Convalescent Home at Lindon Grove, Blackrock. The clinical instruction in medicine and surgery is given by Dr. Quinlan, Dr. Mapother, Dr. O'Leary, and Dr. Cryan.

A Special Ward for the treatment of the Diseases of Women has been opened under the care of Dr. J. A. Byrne, Gynæcologist to the Hospital.

The MATER MISERICORDIÆ HOSPITAL is the largest of the Dublin Hospitals, and is intended to be much extended. It is situated at the northern side of the town. The new wing is specially reserved for the admission of cases of fever and other contagious diseases. A special course on these subjects is given.

There are six resident pupils appointed during the Winter Session, and four during the Summer Session. Good lodgings can be had very cheap close to the hospital. Prizes to the value of £30 are awarded at the end of the Winter Session for the best reports on the cases under treatment in the hospital.

JERVIS STREET HOSPITAL is one of the oldest established charitable institutions in Dublin, having been founded in 1721. It is situated in a part of the city not otherwise provided with hospital relief, and which, from its commercial character, supplies the hospital with an abundance of surgical cases. Like St. Vincent's Hospital, its nursing arrangements are under the charge of a community of Sisters of Charity. The hospital, being found inadequate to the demands upon it, is in process of being rebuilt.

The LEDWICH SCHOOL was founded in 1810 by the well-known Dr. Kirby, and since then has fully sustained its prestige. Its name was bestowed upon the school as a tribute of respect to the late T. H. Ledwich, who sacrificed [illegible] in an increasing effort to promote its welfare. It is situated in Peter Street, not five minutes' walk from the College of Surgeons, the Meath, Vincent's, Coombe Lying-in-Hospital, and Mercer's Hospital, and in the same street with the Adelaide Hospital and the Carmichæl Medical School, and ten minutes' walk from the Catholic University School, the School of Physic, and the City of Dublin Hospital. An Introductory Lecture will be given at this school by Dr. Mason, on November 3rd.

MERCER'S HOSPITAL, William Street, founded A.D. 1750. —This hospital is situated in the centre of the metropolis, in the midst of a densely-crowded population, and its doors are opened at all hours for the reception of accidents and of acute cases. Dispensaries are held daily, and are largely attended. Special instruction is given in cutaneous and infantile diseases. From the large number of accidents which from its position come to the hospital, students are afforded ample opportunities of rendering themselves familiar with the nature and treatment of disease in its various forms, and of acquiring dexterity in the dressing and manual operations of minor surgery.

RICHMOND, WHITWORTH, and HARDWICKE HOSPITALS.—Accommodation: Hardwicke Hospital, 120 beds; Whitworth Hospital, 82 beds; Richmond Hospital, 110 beds; total, 312 beds.

These hospitals are visited each morning at nine o'clock by the physicians and surgeons, and, in addition to the usual bedside instruction, Clinical Lectures are delivered on the most important cases. Special instruction is also given on various branches of Medicine and Surgery.

The Truss Establishment, for the distribution of trusses to the ruptured poor of Ireland, is connected with these hospitals. There is a very large ophthalmic, aural, and dental dispensary, and the respective surgeons give instruction in these important subjects.

Eight resident clinical clerks and the dressers are appointed each half-year, and provided with furnished apartments, fuel, &c., &c. These appointments are open not only to advanced students as formerly, but also to those who are qualified in medicine or surgery. A House Surgeon for the Richmond Hospital is elected biennially, and receives a salary.

The RICHMOND LUNATIC ASYLUM, containing 1,000 beds, adjoins these hospitals.

The CARMICHÆL COLLEGE OF MEDICINE AND SURGERY has been removed from North Brunswick Street to its new premises in Aungier Street. The edifice is now rapidly approaching completion, and on the beginning of the session (1st October), everything will be ready for the reception of students. As the buildings are entirely new from their foundation, the directors have been able to provide all the most recent improvements, and they have spared no expense to render every department fully adequate to the requirements of the most advanced teaching of Medicine and Surgery.

The School is most conveniently situated, being in immediate proximity to the Meath, Adelaide, and Mercer's Hospitals, and it is connected by its teachers not only with these hospitals, but also with those of the House of Industry and the City of Dublin.

We would direct attention specially to the dissecting-rooms, and to the physiological laboratory. The former are spacious, well ventilated, and admirably lighted from the top as well as from the two sides; the latter is completely furnished with every requirement for the practical training of students in physiological and histological research.

Additional Lectures in Anatomy, Physiology, Materia Medica, &c., delivered in the *evening*, will be one of the new features in the school.

Two Scholarships, the "Mayne" and the "Carmichæl," each value £15, and prizes to the value of over £60 on the foundation of the late Mr. Carmichæl, are offered annually. The Carmichæl Scholarship is for students commencing their third year, and will be examined for in the last week in October. The examination for the "Mayne," and for the other prizes, will not be held until the close of the Session.

DR. STEEVEN'S HOSPITAL AND SCHOOL are situated close to the Kingsbridge Terminus of the Great Southern and Western Railway, and therefore occupy a position of their own, far removed from the other medical institutions.

Immediately adjoining is St. Patrick's (Swift's) Asylum for the Insane.

Digitized by Google

There is accommodation for residence of seven surgical and four medical residents; besides whom the resident-surgeon receives house pupils. The fees payable for the privilege of residence are twenty-one guineas, winter; fifteen guineas summer six months. Students have apartments, coal, gas, and furniture.

Accommodation outside the hospital, in the neighbourhood, is arranged by the hospital authorities.

The examination for two Midwifery Assistants is held on the last Saturday in November. Salary £30.

Candidates must be in at least their second year, have attended Practical Midwifery in the Maternity Department, and be entered on the books of the school.

Gold medals will be awarded in each year's class.

As we have said, certain hospitals have no special affinity with any college or school. Of these are the Meath and Adelaide Hospitals.

The MEATH HOSPITAL, which is also the public infirmary of the county of Dublin, containing 120 beds, and now in the 125th year of its existence, ranks among the oldest of the charitable institutions of this city. It is situated on the side southern of the city, upon about three acres of ground, formerly called "The Dean's Vineyard." The original Meath Hospital, situated on the Coombe, was opened in 1753. The foundation-stone of a new Meath Hospital, on the Coombe (now the Coombe Lying-in Hospital), was laid out by Lord Brabazon, 10th October, 1770: this hospital was, in 1774, constituted the County Dublin Infirmary by Act of Parliament. The present building, in Heytesbury Street, was opened in 1822, since which time the building has undergone considerable enlargements and improvements. In 1830 the theatre for operations and lectures was erected. In 1852-3 the Collis Wards were added as a memorial to Maurice Collis, twenty-five years surgeon to the hospital. In 1865 the "Smyly Ward," built for the special accommodation of children, was opened by the Lord-Lieutenant, Lord Woodhouse.

The ADELAIDE HOSPITALS, recently much enlarged, are in Peter Street, next door to the Ledwich School, and within a few minutes' walk of the Carmichæl Medical College of Surgeons and the University. From the 1st of October the physicians and surgeons will visit the wards, and give instruction at the bedside, at the advertised hours.

There is a large detached fever hospital and also wards for infants and children. Special hours are devoted to clinical instruction in the Diseases Peculiar to Women and students are individually instructed in the use of the Stethoscope, Ophthalmoscope, Laryngoscope, and Microscope. Three resident pupils are selected half yearly. Prize examinations are held at the termination of the Session. The large dispensaries afford facilities for the study of eye, ear, throat, and cutaneous diseases, as well as minor Surgery and Dentistry.

SPECIAL HOSPITALS.

The Special Hospitals of Dublin are the Rotunda and Coombe Lying-in Hospitals, Cork Street Fever Hospital, Pitt Street Children's Infirmary, St. Mark's Ophthalmic Hospital, the National Eye and Ear Infirmary, and two Orthopœdic Hospitals.

COOMBE HOSPITAL.—This hospital has been rebuilt and refurnished, and has sixty-five beds, was founded in 1826, and was incorporated by Royal Charter in 1867, thus enabling its medical officers to issue diplomas qualifying the holders to practise midwifery. This hospital is situated in the centre of a district densely populated by the lower orders, and thus affords the amplest opportunities for practice. It receives about 700 labour cases within its walls, while those attended as extern amount to more than double that number. Moreover, the chronic ward for the reception of cases of the diseases of females gives admission to about 80 patients annually. The fee for attendance is £8 8s. for six months as extern, and £18 18s. as intern pupil. During that period the student attends on given nights in each week, and takes charge in his turn of any case that may be admitted to the labour wards, or may call for his assistance outside. Two resident pupil midwifery assistantships, and a clinical clerkship, are obtainable annually, by competitive examination, for which all pupils who have obtained their midwifery diplomas are eligible.

The PITT STREET CHILDREN'S INFIRMARY, established 1821, is situated close to Mercer's Hospital and the College of Surgeons. It was founded to provide treatment specially for children, and to teach that special branch of disease. Dr. Moore and Dr. Churchill are the medical officers.

ST. MARK'S OPHTHALMIC HOSPITAL AND DISPENSARY FOR DISEASES OF THE EYE AND EAR.—This is the oldest and largest special ophthalmic hospital in Dublin, and was founded by Sir William Wilde. Instruction is given on the mornings of Mondays, Tuesdays, Thursdays, and Fridays, from 11 to 1 o'clock, and operations are performed on Wednesdays and Saturdays from 11 to 1 o'clock. A surgeon resides in the institution, and receives a salary of £80, besides rooms, gas, coal, &c.

THE ROTUNDA HOSPITAL.—This well-known and time-honoured institution possesses a character as a School of Midwifery which needs no comment. It is not, however, as generally recognised as it deserves to be, as also a great school of gynæcology. The institution consists, in fact, of two distinct hospitals, viz., the lying-in hospital, into which some 1,200 cases of labour are admitted annually, and the Hospital for the Treatment of Diseases Peculiar to Women, into which some 500 patients are now annually admitted during the course of the year. The present master, Dr. Lombe Atthill, as is well known, devotes special attention to this department of the charity. There is also a large extern maternity in connection with the hospital. Every facility is afforded for the study of the special departments of medicine to which the hospital is devoted, and both students and midwives are granted a diploma on passing an examination.

The Clinical Clerkship, value £30 a year, tenable for six months, is adjudged, after open competitive examination, to any pupil who has attended the full course of instruction in the hospital, but who has not obtained a registerable qualification.

CORK STREET HOSPITAL is the only special fever hospital in Dublin, contains 200 beds, and is mainly supported by Government. One or more medical pupils are elected by the Governors for a six months' residence, for which a special certificate is given. Extern students are also admitted for the same term. Fee, three guineas. Further particulars of Dr. Atkins, Registrar and Resident Medical Officer.

NATIONAL ORTHOPÆDIC AND CHILDREN'S HOSPITAL OF IRELAND for the treatment of Club-foot, Contractions and Distortions of the Limbs, Spinal and all other Bodily Deformities and Diseases Peculiar to Children, 7 Adelaide Road, Dublin.—Mr. Ormsby attends daily from 11 to 12 o'clock, and gives clinical instruction on the intern cases.

The hospital is capable of containing 36 beds, for the reception of several cases of deformity. There is a large general dispensary for extern patients held on Tuesday, Friday, and Saturday, 11 to 12. Operations performed on Fridays. Students and practitioners are allowed to attend the clinical instruction.

DUBLIN ORTHOPÆDIC HOSHITAL, 11 Usher's Island, contains 20 beds for the treatment of deformities, and an Infirmary for Contagious Disease should such occur. It is under the surgical management of Mr. Swan. Twelve beds are free.

THE DENTAL HOSPITAL IN DUBLIN.—This is the only hospital in Dublin solely devoted to the treatment of Diseases of the Teeth and Deformities of the Mouth, which will afford gratuitous relief to the suffering poor. It is open daily from 9 to 10 a.m.

CORK OPHTHALMIC AND AURAL HOSPITAL has a special throat department, it is the only special institution of the sort in the south of Ireland, and is under the care of Dr. H. Macnaughton Jones. It contains twenty-six beds, and has an average extern attendance of 1,700 patients. A Resident Pupil is chosen every three months, and Clinical Assistants are appointed by the Surgeon.

INTRODUCTORY LECTURES IN THE DUBLIN SCHOOLS AND HOSPITALS.

School of Physic—None.
Royal College of Surgeons—Dr. Roe, Oct. 27th, 1 p.m.
Catholic University—Dr. Nixon, Nov. 3rd, 3 p.m.
Dr. Steevens' Hospital and School—None.
Meath Hospital—Dr. Moore, Nov. 3rd, 10 p.m.
City of Dublin Hospital—None
Sir Patrick Dun's Hospital—None.
Mercer's Hospital—None.
Richmond Hospital—Mr. McDowel, Oct. 30th, 10.30 a.m.
Mater Misericordiæ Hospital—Mr. Kilgariff, Nov. 4, 11 a.m.
Rotunda Hospital—Dr. Atthill, Nov. 5, 4 p.m.
Carmichael School—Dr. Gordon, Nov. 1, 11 a.m.
Ledwich School—Dr. Mason, Nov. 3, 12 a.m.
St. Vincent's Hospital—None.

MEDICAL EDUCATION IN SCOTLAND.

THE UNIVERSITIES.

THE fees for the degrees in all four of the Scotch Universities are the same, viz.: M.B., £15 15s. (£5 5s., being payable at each of the three examinations); C.M., £2 5s. (in addition to the fees of M.B.); M.D., £5 5s. (in addition to the fees for M.B.); and £10 for Government stamp.

UNIVERSITY OF EDINBURGH.

This is a qualifying and teaching body, and has complete Faculties of Theology and Law, equally with Medicine. Prior to commencing medical studies the student must pass a preliminary examination in English, Latin, and arithmetic, the elements of mathematics, and the elements of mechanics. An examination in at least two of the following subjects is demanded before being admitted to a professional examination, in addition to the foregoing subjects, viz.: Greek, French, German, Higher Mathematics, Natural Philosophy, Logic, Moral Philosophy. The University confers three degrees, medical and surgical qualifications being granted—M.D., M.B., and C.M. The C.M. is not conferred unless the M.B. be taken at the same time. For the degrees of M.B. and C.M. four years of professional study must be completed after passing a preliminary education recognised by the Medical Council. A degree in Arts of any British University is held to supersede the preliminary examination. Of the four years of professional study, one must be passed in the University of Edinburgh, and another of such four years must be in some other university entitled to grant the degree of M.D. The M.D. degree is conferred on Bachelors of Medicine who have attained the age of twenty-four years, and who present a thesis to be approved by the Medical Faculty. The lectures of several extramural lecturers in Edinburgh, as well as those at the London medical schools, and such teachers in the provincial schools approved by the University Court, are recognised, subject to certain conditions.

Every candidate for the degrees of M.B. and C.M. must give sufficient evidence by certificates—1. That he has studied each of the following departments of medical science, namely: Anatomy, Chemistry, Materia Medica, Institutes of Medicine or Physiology, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Children, and General Pathology, each during courses including not less than one hundred lectures; Practical Anatomy, a course of the same duration as those of not less than one hundred lectures; Practical Chemistry, three months; Practical Midwifery, three months at a midwifery hospital, or a certificate of attendance on six cases from a registered medical practitioner; Clinical Medicine, Clinical Surgery, courses of the same duration as those of not less than one hundred lectures, or two courses of three months' lectures, being given at least twice a week; Medical Jurisprudence, Botany, Natural History, (including Zoology), during courses including not less than fifty lectures. 2. That he has attended for at least two years the medical and surgical practice of a general hospital which accommodates not fewer than eighty patients, and possesses a distinct staff of physicians and surgeons. 3. That he has been engaged for at least three months, by apprenticeship or otherwise, in compounding and dispensing drugs at the laboratory of a hospital, dispensary, member of a surgical college or faculty, licentiate of the London or Dublin Society of Apothecaries, or a member of the Pharmaceutical Society of Great Britain. 4. That he has attended, for at least six months, by apprenticeship or otherwise, the out-practice of a hospital; or the practice of a dispensary, physician, surgeon, or member of the London or Dublin Society of Apothecaries.

UNIVERSITY OF ST. ANDREW'S.

This University confers the degree of M.D. (certain exemptions being made to ten practitioners yearly), M.B., and C.M. Two years of study of each candidate must be in one or more of the following Universities, viz., the University of St. Andrew's, Glasgow, Aberdeen, Edinburgh, Oxford, and Cambridge; Trinity College, Dublin; Queen's College, Belfast; Queen's College, Cork; and Queen's College, Galway.

The degree of M.D, is conferred on any registered practitioner above the age of forty whose professional position is such as to entitle him to that degree, and who shall, on examination, satisfy the examiners of the sufficiency of his professional knowledge; provided always that degrees will not be conferred under this section to a greater number than ten in any one year. The examinations are held yearly, towards the end of April. Candidates must lodge with the Dean of the Medical Faculty the following certificates, along with application for admission to examination:—1. A certificate of age, being a baptismal certificate or affidavit of age. 2. Holograph certificates from at least three medical men of acknowledged reputation in the medical profession, or in medical schools, recommending the candidate to the Senatus for the degree, and testifying to his professional skill and position. As only ten can graduate yearly, candidates will be selected whose service and certificates seem to the Medical Faculty to present the highest professional claims, and where these seem equal preference will be given to age and priority of application. 3. Candidates, when notified for examination, shall remit a portion of the graduation fee (viz., £15 15s.) This sum shall be forfeited should the candidate fail to appear, or to graduate at the time appointed. 4. A satisfactory examination, written and *vivâ voce*, must be passed in the following departments, viz., Materia Medica and General Therapeutics, Medical Jurisprudence, Practice of Medicine and Pathology, Surgery, Midwifery and Diseases of Women and Children.

UNIVERSITY OF GLASGOW.

This is both a teaching and examining body. It confers three degrees, viz.: Bachelor of Medicine, Master of Surgery and Doctor of Medicine. Before graduating the student must have been engaged in medical study for four years one of which must have been spent at the University of Glasgow, and the others at some university or school recognised by the Glasgow University. A *medicus annus* is constituted by two coures of 100 lectures each, or by one course of 100 lectures, and two of 50 each. Two preliminary examinations must be passed, one before commencing study, and the other before appearing at the first professional examination. A degree in Arts (not honorary) exempts the student from these examinations. The hospital practice is attended chiefly at the Western Infirmary, to which several of the professors are physicians and surgeons. Numerous other medical institutions exist in the city, and the fact that hospital appointments in this city are virtually life ones, causes a reasonable and justifiable increase in their number from time to time. The University recognises several extramural lecturers.

Bursaries tenable by Medical Students.—The Brisbane Bursary, of £50 yearly, held for four years by a student of medicine who is a Master of Arts. The Walton Bursary, of £36 yearly, held by a medical student (a native of England being preferred) for four years. The Logan Bursary, of £16 yearly, tenable by a medical student for four years. Two Rainy Bursaries, value £20 per annum each, open to medical students who have just completed the second year of professional study, and tenable for two years. The Armagh Bursaries, three in number, amounting each to £25 yearly, for three years, open to students of divinity, law, and medicine, who have taken the degree of M.A. The Macfarlane Bursary, value £40 per annum, and tenable for three years, open to students who have attended the first session of their professional study in the University of Glasgow, and who have passed in all the seven subjects of the Preliminary Examination for M.B. The Marshall Bursary, value £17 per annum, and tenable for four years, open to students entering the Medical Faculty, and awarded by competition on the subjects of the Preliminary Examination. The Lorimer Bursary, value £50 per annum tenable by a medical student for three years.

UNIVERSITY OF ABERDEEN.

This University is entitled to confer degrees in all the Faculties, and is a teaching body as well. The curriculum of study is nearly the same as in the University of Edinburgh, One year must be passed at Aberdeen. Another of such four years must be either in this University or in some other university entitled to give the degree of M.D. With regard to fees, each candidate for the degree of M.B. must pay a fee of £5 5s. in respect of each of the professional examinations. If he desires to be admitted to the degree of M.B. only he will not be required to pay any further fee, in addition to the £15 15s.; but on admission to the degree of C.M. he must pay a further fee of £5 5s., in addition to the fees for the M.B. degree. Besides the Royal Infirmary, students have the opportunity of attending several other local institutions. Perpetual fee for hospital practice is only £16. The professional examinations are held twice in each year; namely, in April and July, directly after the close of the winter and summer sessions.

THE COLLEGES.

Royal College of Physicians, Edinburgh.—This, like the

Digitized by Google

Sister College of London, is exclusively a qualifying body. In conjunction with the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Edinburgh, this College grants a double qualification, and registerable as such. Each applicant for professional examination must previously have passed the preliminary examination prescribed by the General Medical Council. Exemption is made in the case of masters or bachelors of Arts of any British University and certain recognised foreign Universities. Candidates who may have already passed the first professional examination of any body approved of by the College will be at once admitted to the second part of the examination.

The Fellowship is conferred only by election, and the candidate must at least have been a member of the College for one year previously, and have attained the age of twenty-five years.

The Membership is conferred on licentiates of the College, or graduates of a British or Irish University, with whose knowledge the College may be satisfied, and who has attained the age of twenty-four years.

The Licence.—The regulations are nearly the same as those for the joint examinatien for the Scotch double qualification.

The professional examination will be divided into two parts, according to the following arrangement of subjects: 1. Anatomy, physiology, chemistry. 2. Materia medica and pharmacy, pathology and pathological anatomy, practice of medicine, surgery, midwifery, medical jurisprudence, clinical medicine. No candidate will be admitted to the first examination until the end of his second winter session, or to the second until he has completed four years of professional study. The examinations will be partly oral, partly in writing.

Qualification in Public Health.—The College now confers a certificate of competency in public health The examinations are held in April and October. Fee, £10 10s.

Fees.—The fee payable by a licentiate is £10 10s. In the case of unsuccessful candidates the fee is returned, minus £4 2s., retained to defray the expenses of examination. The fee to be paid by a member is £31 10s. When a licentiate is raised to the rank of a member, he pays £21. When a member is raised to the rank of a fellow, the fee is £31 10s., exclusive of stamp duty, which amounts to £25. All candidates for fellowship or membership must lodge their fees, and the amount of stamp duty payable at the time to Government, with the treasurer, previously to presenting their petitions.

Royal College of Surgeons, Edinburgh.—Candidates for the diploma of this College must have followed a course of study in some University, or in an established school of medicine, or in a recognised provincial school. Candidates already qualified are admitted on certain exceptional conditions.

Preliminary Examination.—All candidates for the diploma of the College must have passed the complete examination prescribed by the General Medical Council, and have their names inscribed on the register of medical students at the commencement of their medical studies. The preliminary examination of certain recognised bodies is accepted by the College.

Professional Examination.—Candidates commencing professional study after September 16, 1886, must have been engaged, during four years after the preliminary general education, in professional study, which shall include not less than four winter sessions, or three winter and two summer sessions' attendance at a recognised medical school.

Professional Examination.—The professional examination is divided into two, the one oral, the other written. The first examination embraces anatomy, physiology, and chemistry. The second examination embraces surgery and surgical anatomy; also medicine, midwifery, materia medica, and medical jurisprudence; and does not take place prior to the termination of the winter session of the last year of study.

The Fellowship is conferred only on candidates who have obtained a diploma from this College or from either of the Colleges of Surgeons of England or Ireland, or the Faculty of Physicians or Surgeons of Glasgow, and who are twenty-five years of age. The election is by ballot, and three-fourths of the votes are required to be in the candidate's favour, and he has to subscribe certain bye-laws of the College. Fellows are forbidden to keep open shops, to be connected with secret remedies, or indelicate advertisements or publications.

The Licenses.—The regulations are almost the same as those for the joint examinations conducted by the Colleges of physicians and surgeons.

Dental Diploma.—Every candidate for the dental diploma must have attended the general lectures and courses of instruction required at a University or an established medical school, recognised by the College as qualifying for the diploma in surgery. The special courses of instruction may have been followed in a recognised dental hospital or school, or by teachers recognised by the College. The fee for the diploma is £10 10s. Certain exceptions are made in the examination of candidates who were in practice before the first day of August, 1878, or those not in practice, but who had commenced their apprenticeship as dentists before the first day of August, 1875.

In order to test more effectually the practical knowledge of candidates, recent dissections, anatomical specimens, and articles of the materia medica will be employed during the examinations; and all candidates will be required to write our formulæ of prescriptions. They will also be subjected to a practical clinical examinatlon in the surgical hospital, including the application of surgical apparatus, bandages, &c.

No candidate will be admissibe to examination who has been rejected by any other licensing board within the three months preceding his application to be examined.

Those candidates who have passed the first professional examination during the 31st December, 1878, will be required to pay, as under the old regulation, a fee of £6 for the second examination, providee they appear for that examination prior to 1st January, 1881; and in the event of being unsuccessfui £2 will be retaiued.

THE SCOTCH DOUBLE QUALIFICATION.

The Royal College of Physicians of Edinburgh. by a certain arrangement, grants conjointly with the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons, after one series of examinations, a double qualification, two diplomas being given and registered under the Medical Act as medical and surgical qualifications, thus: Lic. Roy. Coll. of Phys. Edin. and Lic. R.C.S. Edin., or Lic. Roy. Coll. of Phys. Edin. and Lic. Eac. Phys. and Surg., Glas., according as the case may be.

By the understanding subsisting between these bodies, the College of Physicians take exclusive charge of the examination in medicine; and the College of Surgeons or the Glasgow Faculty, of that in surgery; while departments common to both medicine and surgery are examined by a board in which each body is represented. Such arrangements as these were contemplated by the Medical Act, and authorised by Section XIX., and those under consideration were sanctioned by the Medical Council, 7th Augst, 1859.

Candidates having fulfilled the full curriculum are subjected to two professional examinations. Hereafter the preliminary examination must be passed before commencing professional study, and must be otherwise conformable to the regulations of the Medical Council.

School of Medicine, Edinburgh.—The lectures of this School qualify for the University of Edinburgh and the other Universities, and the Royal Colleges of Physicians and Surgeons, Edinburgh, London, and Dublin, and the other medical and surgical boards.

In accordance with the statutes of the University of Edinburgh, any four of the medical classes required for graduation, or two complete *anni medici*, may be studied at this school, each of which may be constituted by attendance on two of the six-months' courses, or on one of these and two three-months' courses. It is always provided, however, that the fee for any class taken for graduation in the University of Edinburg shall be the same as that charged by the University for the corresponding class.

The whole of the education required for graduation at the University of London may be taken at this school. The minimum cost of the education of this School of Medicine for the double qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons, including the fees for the joint examinations, is £85, which is payable by yearly instalments during the

Digitized by Google

period of study; and the minimum cost for the single qualification of either Physician or Surgeon, including fees for examination, is £85.

Royal Infirmary, Edinburgh.—Clinical instruction is afforded at this institution under the supervision of Professors of the University and ordinary physicians and surgeons to the Infirmary. Special instruction is given on diseases of women, physical diagnosis, and diseases of the eye. Separate wards are devoted to fever, venereal diseases, diseases of women, diseases of the eye, &c. The perpetual fee, in one payment, is £10; the annual fee, £5 5s.; half-yearly, £3 3s.; quarterly, £1 11s. 6d. Separate payments for two years entitle the student to a perpetual ticket. No fees are payable for any surgical or medical appointment.

Glasgow Royal Infirmary School of Medicine.—The winter session will commence on October 29th. Courses of lectures are given on all the subjects required by the licensing bodies for qualification, and lectures are also given on practical physiology, operative surgery, aural surgery, dental surgery, and diseases of the eye. During the summer lectures on insanity are given by Dr. A. Robertson, and the City parochial asylum under his charge is free to students of this school. Students have unusual facilities for the study of anatomy, the supply of subjects being practically unlimited.

Class Fees.—For each course, first session, £2 2s.; second session and perpetual, £1 1s. Students who have attended a first course elsewhere can enter on the second course on payment of £1 1s. Anatomy, first winter session, £4 4s.; summer session, £1 1s.; second winter session, £4 4s.; afterwards the fee for lectures and practical anatomy is £1 1s. per session. Lectures on Diseases of the Ear, £1 1s.; with clinique to those who are not students of the hospital, £2 2s. Clinique on dental surgery free to students of the hospital, to others £1 1s. Lectures on diseases of the eye, £1 1s.

Glasgow Royal Infirmary.—Number of beds, 570. In addition to the ordinary medical and surgical wards, there are separate wards for the treatment of venereal diseases and the diseases of women, whilst diseases of the eye, ear, throat, and teeth are especially treated at the dispensary. Courses of clinical medicine and surgery are given by the physicians and surgeons, and post-mortem examinations are conducted in the pathological theatre by the pathologists, who also give practical instruction in pathological anatomy and histology.

Appointments.—There are five physicians' and five surgeons' assistants. The appointments can be held for six or twelve months, and are open to students who have passed all their examinations except the last, or to gentlemen who have a qualification in medicine or surgery. Clinical assistants, dressers, dispensary clerks, and pathological assistants are selected from the students.

Fees for hospital practice and clinical lectures, first year, £10 10s.; second year, £10 10s., afterwards free. For six months, £6 6s.; three months, £4 4s. Students who have paid 20 guineas at another hospital for its perpetual ticket are admitted six months for £2 2s., or one year for £3 3s. Vaccination certificate, recognised by Privy Council, £1 1s.

Anderson's University, Glasgow.—This is exclusively a teaching body. In addition to its offering excellent opportunities for acquiring a good medical education, instruction is given in the other branches of a liberal education, advantage of which might profitably be taken by medical students generally. The expenses of this institution, as already mentioned, are exceedingly moderate. Extensive opportunities for dissection are offered, under the guidance of the very talented lecturer on anatomy.

In connection with this College, there are five hospitals and dispensaries for special diseases, to all of which students are admitted.

The following scholarships will be competed for at the commencement of winter session, 1878-79:—

(1.) A scholarship, value £20, for students of the College entering upon their *third* winter of medical study.

(2.) A scholarship, value £10, for students of the College entering upon their *second* winter of medical study.

The subjects of examination for the £20 scholarship will be Anatomy, Physiology, and Surgery. In Anatomy the examination will be limited to the following subjects, viz.:—The Joints, the Minute Anatomy of the Thoracic and Abdominal Viscera, Practical Examination on Recent Dissections. In Physiology the examination will be limited to the Cerebro-Spinal Nervous System. And in Surgery the examination will be limited to Hernia, Dislocations, Fractures, Diseases of the Bones, Aneurism, and Diseases of the Genito-Urinary Organs. The examination will be partly *viva voca* and partly written.

The subjects of examination for the £10 Scholarship will be Anatomy and Chemistry. In Anatomy the examination will be limited to the Bones, Joints, and Muscles. In Chemistry the written examination will be on some subject taken from the Chemistry of the Sugars and Alcohols (Text-book, Armstrong's "Organic Chemistry." The *viva voce* examination will embrace the Chemistry of the Non-Metallic Elements (Text-book, Wilson's or Williamson's "Chemistry.") There will also be a practical examination, embracing the analysis of a simple salt.

The examinations for the Scholarships will take place in the last week of November, 1879.

In addition to these scholarships, a prize of £5 will be awarded in the junior anatomy class at the close of the winter session, and one of similar value in the chemistry class for students of the first year.

Further particulars may be obtained on applying to Dr. A. M. Buchanan, Dean of the Medical Faculty.

NOTICE.—The Editor desires to thank the Deans of the various Medical Schools for supplying him with the information respecting the institutions with which they are connected. [As this number is devoted exclusively to information necessary for students intending to join one or other of the various medical schools; and for those, who, having passed their curriculum, are about to enter the ranks of the profession, the ordinary matter which fills our columns is necessarily deferred to next week. Should any of our readers desire to present this number to a patient or friend who contemplates sending his son to a medical college, our Publisher will be happy to supply him with a duplicate free of cost.]

PSYCHOLOGY AND THE NERVOUS SYSTEM.

By J. HUGHLINGS-JACKSON, M.D., F.R.S.,

Physician to the National Hospital for the Epileptic and Paralysed, and to the London Hospital.

(*Continued from page* 241.)

I will now give examples of the confusion of the two things in medical writings, and I am ready to say that I can illustrate the confusion very well from my own writings. Thus in a paper on the Physiology of Language, 1868, I have used the expression "psychical movements." Now a movement, in the sense of there being a muscular contraction, or discharge of a motor centre, is no more psychical than retinal vibrations are colour. That term might be used, as I intend to use it, as a short expression for the psychical side of what is physically a discharge of motor centres slight or strong enough to produce contraction of muscles; in this sense words are psychical movements. But when writing the paper above quoted from, I did not use the term in this way, but wrote under a confusion of psychical with physical states, or with perhaps no clear thoughts on each of the two things.

In the "Royal London Ophthalmic Hospital Reports," vol. v., p. 14, I speak of the "mind" as being made up of sensory and motor phenomena; it should have been "the organ of mind."

I give another quotation and intercalate words rectifying the original blunders.

When speaking of convulsions (a clotted mass of movements) as being owing to discharges of *convolutions* ("Study of Convulsions," *St. Andrew's Medical Graduates' Transactions*, vol. iii., 1870), I say—"It is asserted by some that the cerebrum is the organ of mind, and that it is not a *motor* organ. Some think the cerebrum is to be likened to an instrumentalist, and the motor centres to the instrument—one part is for ideas, and the other for movements. It may, then, be asked, How can discharge of part of a *mental* organ produce *motor* symptoms only? I say motor symptoms only, because, to give sharpness to the argument, I will suppose a case in which there is unilateral spasm without loss of consciousness. *But of what 'substance' can the [organ of] mind be composed, unless of processes representing movements and impressions; and how can the convolutions differ from the inferior centres, except as parts representing more intricate co-ordinations of impressions and movements in time and space than they do?* Are we to believe that the hemisphere is built on a plan *fundamentally* different from that of the motor tract? What can [the anatomical substratum of] an 'idea'—say of a ball—be, except a process representing certain impressions of surface and particular *muscular adjustments?* What is recollection but [a mental state occurring during] a revivification of such processes, which, in the past, have become part of the organism itself? What is delirium, except [mentation occurring during] the *disorderly* revival of sensori-*motor* processes received in the past? What is [the physical process during] a mistake in a word, but a wrong *movement*—a chorea? Giddiness can [on its physical side] be but the temporary loss or disorder of certain relations in space, chiefly made up of muscular feelings. Surely the conclusion is irresistible, that [the physical conditions of] 'mental' symptoms from disease of the hemisphere are fundamentally like [those in] hemiplegia, chorea, and convulsions, however specially different. They must all be due to lack, or to disorderly development, of sensori-*motor* processes."

In the *Medical Times and Gazette*, November 17, 1868, p. 526, I write (italics in original), "*The psychical, like the physical processes of the nervous system, can only be functions of complex combinations of motor and sensory nerves.*"

This, which is vague in other ways, should be that the nervous arrangements which are the substrata of psychical states, are like all other nervous arrangements, sensori-motor.

I quote a more recent paper, and intercalate words rectifying the blunder.

Digitized by Google

"We do not make enough use of cases of convulsions in our physiological studies of [the substrata of] mind.

These samples are enough to illustrate my blunders and leave me free to criticise such blunders more generally.

Now, for the sake of argument, let us grant for the moment that psychical states and nervous states *are* one and the same thing. Are not those who take this view as much bound as those who take any other to work at the problem of what particular parts of the body this mind—brain—represents, and of the order in which they come into activity, in ideation, perception, emotion, &c. To take the view mentioned is to hold that the nervous system, or its highest divisions, has two functions, one psychical and the other physical. As a physician I do not object to this view in the least, provided real anatomical and physiological work goes along with the psychological. Lewes holds that view, but as a physician, I say nothing critical of his opinion, because he takes the other steps which medical inquiry demands; he studies not only psychology, but gives very definitely and clearly an account of what he considers to be the physical nature of the nervous states which he believes to be only another aspect of psychical states. It is certain that the function of the nervous system is to "store up" and "to expend" energy, and if it have another—a psychical—function, would it not be at least convenient in investigating problems so difficult as epilepsy and insanity to keep the two functions distinct, as we do the glycogenic and the biliary functions of the liver? Suppose a man has, from activity of some part of his ideational centres, a particular idea; we have the mental state, the idea; but we are bound also to consider what parts of the organism the nervous arrangements in activity during that idea represent. *To give a materialistic or morphological explanation of mental states is not to give an anatomical one.* Suppose that for clinical purposes it matters nothing whether we believe (1) that conscious states are parallel with active states of nerve fibres and cells, the nature of the association being unknown, or (2) that mental states and nervous states are the very same thing, or (3) whether we believe that there is a soul acting through a mere mechanism. I wish to insist that to hold any one of these beliefs does not one whit justify us in omitting anatomy. Betwixt our morphology of the nervous system and our psychology there must be an anatomy and a physiology.

It will be assumed (1) that psychical states are always accompanied by physical states, (2) that the physical states are of sensori-motor arrangements—that is, of nervous arrangements representing impressions and movements; (3) that the nature of the connection betwixt the physical and psychical is unknown. Whether we take that view of the nature of the substrata of mind or be content with simply saying that the physical states are states of cells and fibres matters nothing. It makes the problem neither more nor less difficult if we add the words "representing impressions and movements" to the statement "that the substrata of mental states are nerve cells and fibres."

In a future article we shall try to show that the whole nervous system is made up of nervous arrangements representing the organism; that it is a series of more or less complex sensori-motor arrangements representing impressions and movements of all orders; that the lower centres are sensori-motor no one denies; that the higher and highest are so also, is in perfect harmony with the phenomena of epileptic seizures, *le petit mal*, *le grand mal*, epileptiform seizure.

I wish now briefly to show that the above made distinction betwixt the psychical and physical states is not a merely theoretical one; that its non-recognition, or if there be no such distinction its non-separation by artifice, leads to medical errors.

In the first place, its non-recognition leads to verbal explanations; thus hemiplegia has been said to be owing to loss of volition; this is only saying that the patient cannot move the parts paralysed. Chorea has been said to be owing to "disorder of volition." These explanations explain nothing. They appear to do so by harmonising with the popular fallacy that a man has A Will, outside, so to speak, his own mind, and as if there were some part of the nervous system which represented *the* Will. Again, a patient is said to be unable to speak because he has lost the memory of words, which is really only saying that he can't speak; yet it appears like an explanation, because it harmonises with the popular fallacy that we have words and also a memory of words, and thus that there is a centre for memory or ideas of words, and another for the words themselves. Similarly a patient is said to be unable to move because he has lost consciousness. This implies that there is a centre for consciousness which is tacked upon, and independent of the rest of the organism.

All these are explanations of physical conditions by psychical states. Will and memory are only different aspects of the highest and latest states of consciousness, attending energising of our highest cerebral centres.

Again, in some cases of nervous diseases we have classifications on a mixed psychological, and anatomico-physiological method; loss of memory for words, and loss of co-ordination for words. This on any view whatever cannot be correct.

Again, the confusion of states of sensory nerves with sensations leads to the wrong interpretation of one of the most critical symptoms in epilepsy—vertigo. The physical process in vertigo is an excitation of motor centres and because a sensation *attends it* (vertigo), it is put down to some excitation of a sensory nerve. Similarly nausea, pain, &c., are abnormal psychical states as those really admit who use the word feeling for them even when they call them physical.

The confusion of psychical states with physical (nervous) states leads to a wrong interpretation of symptoms. Thus, in acute brain disease, irregularity of the pulse, constipation, vomiting, &c., are often not thought to be dependent on disease of the brain, because the brain is the organ of mind, and is thought of as if it were the mind. But the physical basis of mind is a series of nervous arrangements, representing the circulalatory, respiratory, and digestive system, as well as the rest of the organism.

On the other hand, positive mental symptoms, as in the condition of delirium, are sometimes considered to be valuable evidence of acute primary disease of the brain, when, as a matter of fact, they are of next to no value towards that diagnosis.

We have two parallel studies—psychological and anatomico-physiological. It is manifest that we cannot study the substrata of mind without first knowing, something of mind. What Mill writes ("Comte and Positivism"), p. 66, illustrates this. He is speaking of the phrenological hypothesis.

"And even if that hypothesis were true, psychological observations would still be necessary; for how is it possible to ascertain the correspondence between two things by observation of only one of them? To establish a relation between mental functions and cerebral conformations, requires not only a parallel series of observation applied to each, but (as M. Comte himself, with some inconsistency, acknowledges) an analysis of the mental faculties. . . . ."—(Mill on "Comte and Positivism," p. 66.)

What is to come will be unintelligible, unless the reader bears in mind two things:—

(1) That it is assumed that all nervous centres, from the lowest spinal centres to the very highest cerebral centres (the substrata of consciousness) are made up of nothing other than nervous arrangements representing impressions and movement. The unit of composition throughout the nervous centres is sensori-motor. Of course, all nervous centres are admitted by everybody to be "motor," in the sense that the nervous tissues contain "stores" of molecular motion (are made up of molecules having the energy of position); but by "motor" I mean in this article representing movements of muscles, and some other processes, to be presently mentioned. The fact that movements are not produced by slight gal-

Digitized by Google

vanic or Faradaic currents applied to the cortex beyond Hitzig and Ferrier's region, does not disprove the above assertion. It would be a most marvellous thing if the highest cerebral centres had a fundamentally different constitution from that of the lower.

2. That states of consciousness (ideas, perceptions, volitions, feelings, emotions, and whatever sort of psychical state we may have), although always parallel with nervous states, are utterly different from them.

The two statements are to be borne in mind. Referring to the first as if it were the sole one it may be said that movements do not enter into ideas. The reply is that that is just what is affirmed under No. 2. Referring to No. 2, it may be said that states of consciousness must have something to do with states of brain. That is exactly what is meant; they have something to do with it; for in our experience, psychical states occur along with nervous states.

(To be continued.)

THE ADVANTAGES OF CALOMEL IN THE DISEASES OF CHILDHOOD, WITH ESPECIAL REFERENCE TO TYPHOID FEVER.

By E. MARLETT BODDY, F.R.C.S., F.S.S., ETC.

(Continued from page 242.)

CALOMEL, by reason of its purgative properties, frequently causes green evacuations, and so does castor oil when the child is out of health, but this phenomenon of disease ceases the moment the child becomes well. Therefore the green stools are not by any means produced by the calomel, but are caused by some morbid action going on in the intestines. When the child is ill, the mother will almost invariably tell you that the evacuations are green and slimy. This assertion of the parent alone proves that calomel, when given, is not the originator of green stools, but that they are produced by some morbific influence. I think the colour is very probably caused by an over secretion of bile, which will to a certainty show itself independently of the calomel.

As there is no fear of mercurialisation arising from calomel, as it promotes the elimination of the over-secretion of bile, and as it restores the intestinal canal to its ordinary healthy tone, it is, without doubt, the best purgative we can possibly administer in *all* diseases appertaining to infancy, ignoring, to a certain extent, those of a congenital nature. Mercurialisation can only occur when the drug is allowed to remain and accumulate in the system, and to accomplish this, the best method is to follow the general rule, viz., the administration of the hydrargyrum cum creta; by so doing we shall be decidedly successful. But as this result is not desired, we shall be able to prevent such an untoward complication by administering calomel by itself, or combined with a small amount of sugar; this addition is not at all necessary—in fact, I do not see what advantage can be gained by combining the two. Calomel is quite as efficacious without sugar, therefore it can be well dispensed with.

Regarding a very recent sage discovery made by a certain *savant*, that by giving to an infant calomel and sugar we may very likely poison it through the formation of corrosive sublimate while the compound remains in the stomach, though chemically true, yet I must say it almost verges on puerility; no case of poisoning has, I believe, occurred through the combination of calomel and sugar, and, I dare say, never will. I think we may consider it as bordering on the absurd until a *bonâ fide* case of poisoning, resulting from the administration of calomel and sugar, is brought before the profession, and thoroughly substantiated as such. The discovery is ingenious, to say the least of it, but it is of no practical utility when one considers it in the abstract. However, it is not for this chemical change in the stomach that I am advocating the non-administration of calomel and sugar, but because I do not see what can be possibly gained from the combination of the two. In such matters we can only judge correctly by the relative value of the results obtained, and if calomel produces that which is to be desired by its own inherent qualities (which are not in the least enhanced or diminished by the sugar), then, in *all* cases, I say, of infantile disease, we may with safety and advantage administer it by itself. In dropsy, one of the sequelæ of scarlet fever, some compound jalap powder may be combined with it with advantage, though I have found that calomel alone is equally as efficacious, even supposing there is albuminous urine. Calomel may also be combined with santonin in cases of worms; but of this anon.

We have now ascertained conclusively, I think, that it is highly injudicious to give infants the hydrargyrum cum creta, owing to one ingredient stultifying, we may say, the action of the other, and that it may be left to discretion whether any gain may result from combining calomel with sugar; it now remains for us to determine how we may promote its action to a greater degree, and thereby accelerate a speedier return to health.

To obtain this end satisfactorily, I always make it an invariable rule to administer the calomel at night, and next morning to follow it up with some castor oil, which practice has always resulted by my expectations being realised. Sometimes, on account of the stubbornness of the bowels, owing to neglect, calomel is comparatively powerless as regards its purgative qualities; but it never fails when followed by the castor oil, which seems to stimulate it to fresh exertions, and entirely prevents, in children as well as in adults, the much-dreaded mercurialisation.

This mode of treatment is, as the reader may perceive, remarkably simple, and, consequently, by some may be impugned as being too much so; but simplicity, to my mind, is, or should be, the goal of all things. Complexity and abstruseness show undeniable and unmistakable ingenuity and tact, and great praise is due to those who can obtain the desired end through the media of such channels, but the great fundamental in the treatment of disease is simplicity, which if carried out successfully, is the acme of medical science and the perfection of medical skill.

Some seem to have a grudge and a determined ill will towards calomel; no words and terms are too strong for them to use when they denounce it—in fact, they abuse it with a hearty good-will, and many, I know, would prefer giving no medicine at all than be under the necessity of administering it. Some are truly fearful, and altogether refrain from using it, because so and so may happen; but what catastrophe, one cannot without great difficulty elicit from them; and, supposing we are successful in our endeavours, we find their objections and reasons very vague and unsatisfactory. Some will honestly tell you that to a certainty mercurialisation will occur, and that is the sole reason why they do not use it.

Assuming, for the sake of argument, the correctness of their objections, I do not see why such a result should necessarily occur if it be given with care. If a man chooses to cut his throat with a razor there is no reason why I should follow his example, for I may use the very same implement for other purposes. If a man chooses to poison himself with opium, the same drug, given by me may save another man's life. So it is with calomel; if a man administers it carelessly and injudiciously evil consequences may result; but I may give the very same drug, and good results will ensue.

This dislike to calomel is sheer prejudice, and in many instances approaches the whimsical. I remember being told by a great enemy to calomel that it should never be given save to a ploughman, and then only very gingerly; "Colocynth and hyoscyamus," said he, "for a lady, colocynth and jalap for a gentleman, but colocynth and calomel for a ploughman." This absurd injunction, I need hardly say, I very soon found to be the quintescence of erroneous treatment, besides it was entirely antagonistic to all common sense; for the intestines of a "ploughman" have not, as yet, been discovered to be dissimilar to the intestines of a "lady" or "gentleman." Perhaps, when he made the

Digitized by Google

above remark he was under the impression that there did exist a dissimilarity, and, being of that opinion, considered that a different course of treatment was necessary to meet the various peculiarities of the several intestines.

This digression serves to show what a groundless, illogical abhorrence some have to calomel, for no reason at all except that something prejudicial to the patient may possibly occur, but of what nature they are entirely undetermined upon, unless it be mercurialisation, which is the only objection its opponents can reasonably urge against its administration.

In what diseases or morbid conditions of infancy is calomel indicated, and how should it be administered, whether alone or in combination? Infantile diseases are few in number when compared with those which attack the adult, for the following very cogent reasons:—The constitution of an infant or child has not gone through the wear and tear of life; the lungs have not yet been irritated through inhalation of infinitesimal carboniferous matter; the digestive powers have not yet been impaired through the ingestion of indigestible food; nor have the coats of the stomach been injured by the destructive properties of alcohol, which is regarded by a great majority as a necessary staple of nourishment, and neither is the liver disorganised by habitual drinking.

The most prevalent of all infantile diseases are convulsions, proceeding from either intestinal or cerebral irritation, or from dentition. Those arising from intestinal irritation are sometimes induced primarily from dentition, and in many instances one state is co-existent with the other; and the same may be said regarding those convulsive attacks which owe their origin to cerebral irritation, though the latter condition may exist singly and alone—in other words, we may find one state complicated with the other.

There are two kinds of intestinal irritation: that proceeding from fæcal contents, and that resulting from the presence of worms (which generally belong to the round variety, though sometimes the thread worms are also provocative of convulsions, but they are not of so severe a nature, and they are more common among children averaging from two years and upwards, but rarely found among infants at the breast). Those convulsions proceeding from irritation produced by the accumulation of fæcal matter are easily cured if treated correctly, but are simply aggravated if treated in the usual style, *i.e.*, two or three grains of the hydrargyrum cum creta administered three or four times during the day.

All that these infants require is a calomel powder at bed-time, followed the next morning by some castor oil, which must be continued till the alvine excreta resume their normal appearance, which is too well known—at least, I hope so—to my readers, to need specifying. However, as it is the generally-received opinion of the profession that calomel produces green stools, irrespective of the condition of the patient, I do not think I shall be erring on the wrong side when I tell them that when an infant is in health, the ejecta are as yellow as mustard, whether it is administered or otherwise.

When the convulsive attacks proceed from the presence of worms santonin should be combined with the calomel, and should always be given at night time, to be followed the next morning by some castor oil. This course should be perseveringly persisted in till the motions are natural, which will very soon occur after the expulsion of the parasites. There is not the slightest fear of mercurialisation; nor will the santonin cause retention of urine; and neither will the convulsive attacks be increased; for the very reason that the santonin has not sufficient time to resolve itself into xanthopsin, on account of its being eliminated by the castor oil.

If the convulsions proceed from the irritation produced by the oxyuris vermicularis, or the ascaris vermicularis, commonly known as the thread worm, the best treatment to pursue after the motions have become normal (which will by no means take place till the worms have been expelled), is to inject some infusion of quassia, or salt and water, into rectum. This is comparatively useless if the administration of calomel and its adjunct (if I may so term castor oil), is omitted; for though those minute parasites are supposed to infect the rectum only, they would no doubt be found, though perhaps fewer in number, in the sigmoid flexure and descending colon, if they were searched for on a favourable opportunity, which could only be in a post-mortem.

Depending simply upon an injection in those cases is really not of much benefit; if I may be allowed to make a comparison, it is like clearing out the lower part of a drain pipe, and leaving the upper portion foul and impure.

I have already mentioned the treatment which should be followed out during teething; and I think I have clearly demonstrated the disadvantages accruing from the administration of the hydrargyrum cum creta, and the advantages resulting from calomel; and the remarks I have made regarding them will also apply to nearly all the diseases which are prevalent in infancy.

I shall now pass on to consider those other complaints in which the administration of calomel is advisable. The most common after convulsions is diarrhœa, a medical bugbear, which, when once it commences, frightens the mother, and causes the medical man to resort immediately to a very silly mode of practice, but which at the present day is regarded as a very scientific procedure; and the antidote (presumed to be such), is to be found in the British Pharmacopœia, and accordingly it is given with great faith when diarrhœa shows its hideous presence, in the vain hope of—stopping it.

What is diarrhœa?; and what causes it? and why should we be in such consternation when it occurs? We will examine and answer these questions from a practical common sense point of view. First, what is diarrhœa? The answer is simple, and not at all difficult of comprehension; it is the endeavour of nature to get rid of an evil, and the evil is nothing more or less than a collection of fæcal matter in the intestinal canal. In the majority of cases what else can it be? If the coats, especially the muscular, of the intestines are weakened to any extent in an infant, there are very few chances of its ultimate recovery, because the weakness depends upon some organic mischief, which is not to be remedied by human means. Now if the diarrhœa originates from such a condition all the chalk mixture in the world will not stop it; and most probably, if the administration is too often repeated, the child rather succumbs to the pernicious effects of the astringent than to the diarrhœa.

Here, in these cases, by-the-bye, we administer chalk to stop the action of the bowels, and in other cases we combine chalk and mercury to open them; contradictory, there is no denying, but then it is accounted correct treatment.

Second—What causes diarrhœa? The contents of the intestinal canal and the efforts they make to get out—nothing else; they have done their duty, all nutriment has been extracted from them; they are therefore useless, and nothing else than an incumbrance, and consequently, the sooner they are ejected the better. Nature is of the same opinion, and accordingly sets to work, and would perform her duty alone and single-handed were the fæcal contents in their usual amount and normal condition; but it is not so; the infant, no doubt, has been previously stuffed, or rather overfed, by a too anxious parent. The intestinal canal is too full, and as a natural consequence diarrhœa results, which is the strenuous efforts of Nature to rid herself of an irritating load, which we scientifically endeavour to prevent by the prompt administration of an astringent in the shape of chalk mixture. In these cases Nature requires the helping hand to lift her over the difficulty; not to be thwarted or antagonised by the administration of drugs of an astringent tendency.

Such treatment is not only outrageous, but discreditable to medical science; and I regard it as such, however strongly, and indeed cleverly, it may be advocated by those who are thought more competent to decide than others, for the arguments they advance with such plausibility, are entirely based upon theoretical knowledge (or

Digitized by Google

practical ignorance) rather than upon sound principles of practice, and careful investigation into the varied phenomena of health and disease. I am afraid that we regard the human organism as a piece of workmanship much more complex in its design and working than it really is; and, again, that we too frequently run our heads against the idea that we can mould it just as we please, forgetting that Nature is, on the average, able to conduct her own proceedings to a favourable termination without the aid of science, but is hindered, and, perhaps, completely impeded, by our somewhat too great a hastiness to adopt the so-called scientific treatment of the present day, and which, in infantile diarrhœa, is much more hurtful than otherwise.

One question now remains for our consideration: Why should we look upon the presence of diarrhœa with the eye of suspicion and apprehension? and why should we regard the efforts of Nature to relieve herself as indicative of danger? I think we can easily account for our groundless fears from the fact that we clothe simple diarrhœa in so many technicalities, that many who are either too indifferent, or too ready to take for granted the opinions of others, neglect investigating, and probing to the bottom, the origin of a condition which is quite the reverse of what we imagine to be prejudicial to health.

(To be continued.)

Special.

WORKHOUSE HOSPITAL STATISTICS ON THE ALCOHOL QUESTION.

St. George's Union Infirmary (London) has lately obtained an enviable prominence in the great question, regarding the administration of alcohol in workhouses. Dr. Webster has come in for his share of congratulations on his conversion to the temperance side; and lest any of our readers should not have heard of Dr. Webster's reports, we shall briefly mention what he has done. He has issued a report in which he states that in the St. George's Union Infirmary he has, at the request of the guardians, carried out his intention of limiting the consumption of alcohol in the Infirmary. He has brought down the expenditure for stimulants for one year to £8. He mentions "one or two facts" of a very extraordinary nature. He says: "Prior to their removal to St. George's Infirmary more than thirty old women had been bed-ridden for various spaces of time, ranging from one to seventeen years. They had all been supplied daily with either brandy or beer, or both. The whole are now able to leave their beds; many are able to walk about; some to work. Appetites have been developed for solid material, and an interest is once more taken in the surroundings. I am compelled to ascribe this amelioration of condition to the altered moral state, greater physical energy, and improved food assimilation, brought about by the withdrawal of alcohol."

Every teetotaler must have read these lines with heartfelt satisfaction, for seemingly nothing could be more convincing, or more truthful; and we have no doubt most of the guardians considered that the question was solved, by this authoritative and strong statement of their medical officer.

Unfortunately, there is a fly in the ointment, and there is another side to the question. Dr. Orme Dudfield has taken exception to Dr. Webster's report, and has written the following reply, which is worthy of a more extensive circulation and perusal than that afforded it by the *British Medical Journal*. His letter is hidden in the very small type of our contemporary's correspondence column. *Magna veritas et prevalebit.* The Temperance Movement cannot be bolstered up by half-truths, and we may venture to assert that temperance reform is impeded by "false facts." Dr. Dudfield writes: "In your article on the above subject, in the *Journal* of August 30th, you have properly given prominence to the only statement of 'fact' in Dr. Webster's report, by which he has endeavoured to prove that the withdrawal of alcohol from the aged or infirm inmates of St. George's Infirmary had been attended with beneficial results." We have quoted the passage above.

Dr. Dudfield continues: "Now, so far from these 'interesting words' as you describe them resting on a 'solid foundation of fact' as you suppose, I beg to assure you they are based on error from beginning to end; and as Dr. Webster's predecessor—viz., as medical officer of the old Infirmary of St. George's Union at Kensington for 16 years—I beg to supply that further explanation which you rightly decide ought to be forthcoming. I have seen the old women in question. I remember every one of them, and I affirm without hesitation that they were not bedridden prior to their removal to St. George's New Infirmary, though almost without exception they are very aged, many of them being paralysed or otherwise disabled, and some of them more or less imbecile. They were able to leave their beds when at Kensington; many were able to walk about then as now, and some to work—*i.e.*, some could do a few stitches occasionally when so minded, which the nurse now in charge of them informs me is the extent of the 'work' they do now. I admit it to be probable that the old women had all been supplied with beer daily, for I usually allowed the aged and infirm inmates half-a-pint daily—a quantity of 'alcohol' which Dr. Webster tells me he—though 'by no means' a total abstainer himself—considers sufficient to produce all the evil results from which the old women are supposed to have recovered. But I boldly affirm that not one of them had been supplied with brandy daily—spirits having always been prescribed by me with the strictest moderation, both as to time and quantity, and only in cases of necessity. I wished very much to bring Dr. Webster's statements with regard to the previous condition and the diet of the women to the test of the official records of the Kensington Infirmary, and with that object I obtained permission of the guardians to inspect the medical relief books of that defunct institution. Judge my surprise at being informed by Dr. Webster that all the said books had been destroyed, and that he had never seen them. I do not complain that Dr. Webster did not think it proper to consult me about persons who had been so long under my care, but I think it somewhat remarkable that (as I have ascertained) he did not even take the trouble of finding something about them from my nurses. He frankly admitted to me, however, that he did not pretend exactitude in the statements he had put forth, and that he had simply reported for what it was worth the information given him, long after date, by my poor old patients. Hence the unfortunate error into which he has fallen, which is the more to be regretted as the paragraph referred to (really the most salient in the report) has been very generally quoted by the papers which have dealt with the subject. The explanation of the matter appears to be that Dr. Webster, little dreaming of the importance the guardians would attach to his report, did not exercise that care in collecting his facts, which he would now desire. Writing far from home, I cannot pretend to deal with the other points raised in your article, but as reasons sufficient for asking your readers to suspend their judgment on the question at issue—viz., the value of alcohol in the treatment of disease, so far as it is affected by Dr. Webster's facts, I would beg permission to state that the cost of feeding the inmates of the new Infirmary appears to be considerably in excess of the cost of the old Infirmary; that the ratio of deaths to cases treated was considerably higher during the first year of its operations; and that the gross number of deaths among the indoor sick poor of the Union in 1878-79 was upwards of 20 per cent. more than in 1877-78—a fact to which I long ago called the attention of the guardians. But startling as it may appear to the medical mind, this fact made no impression on the guardians, and seems not to have been thought by them of importance sufficient to call for inquiry, or to need explanation."

This matter cannot rest in its present position, for this plain contradiction of Dr. Orme Dudfield must be sifted to the bottom, and the actual truth revealed. The interests at stake are too great to allow it to be slurred over, and we trust that Dr. Webster, for his own sake, will be able to offer some further explanations in support of his statements. We cannot allow doctored statistics to be used in this controversy. We are glad to notice the Local Government Board has had its attention directed to this question, and we hope that a thorough sifting investigation will be the consequence. We have one result already in the shape of the following report, from another poorhouse.

Digitized by Google

Replying to a circular issued by the Local Government Board, calling attention to the report of Dr. Webster, Medical Officer of St. George's, Hanover Square, Infirmary, on the dis-use of alcoholic stimulants in the treatment of patients under his care, Dr. Charles Gross, Medical Officer of St. Saviour's Union Infirmary, has reported to his Board of Guardians, stating that during the year 1878 a sum of £954 6s. 1d. was spent in his Infirmary for wines, spirits, and beer. Of that amount, £132 7s. 6d. was for beer supplied to the officers as rations; £129 9s., extra diet for certain inmates employed on the labour of the house; £46 14s. 1d. for those employed in the laundry; leaving a sum of £646 5s. 7d. as spent on the sick. The sum of £646 5s. 7d., for stimulants supplied to the sick and infirm, compared most favourably with the amounts spent at other establishments. For instance, Poplar and Stepney Sick Asylums, with an average of 450 patients, spent £625, being £1 7s. 9d. per head; the Central London Sick Asylum, Cleveland Street (226 patients), £278, or £1 4s. 7d. per head; Chelsea Infirmary (240 patients), £349, or £1 9s. 1d. per head; Lambeth Infirmary (540 patients), £564, or £1 0s. 10½d. per head; Central London Sick Asylum, Highgate (446 patients), £613, or £1 7s. 5½d. per head; while at the St. Saviour's Infirmary they had an average of 830 patients, the cost of stimulants £646, or 15s. 6¾d. per head. Dr. Webster took credit in his report, that his low death-rate was owing to the dis-use of alcoholic stimulants, and gave figures to endeavour to prove that statement.

To controvert that the report stated that Poplar and Stepney Infirmary, with an average of 450 patients, had nearly the same proportionate expenditure as Highgate. According to Dr. Webster, they would expect the death-rate to be about the same; but the former had 19 per cent. of deaths; whilst Highgate had the lowest of any—10¼ per cent.

The death-rate in the St. Saviour's Infirmary during the year 1878 was 16 per cent., 3,108 persons being under treatment, with 508 deaths. They must look further, therefore, for a reason for the great differences in the death-rate of similar institutions. The reason was simply in the class of cases admitted into the different infirmaries from different neighbourhoods. In the St. Saviour's Infirmary they got some of the worst classes of disease from some of the worst districts in London, such as St. George's New Town, the Mint, and Lock's Fields. In that respect they resembled the Stepney and Poplar Sick Asylum, whose death-rate was 19 per cent., or 3 per cent. higher than St. Saviour's, where the number of hopeless cases admitted was very great. Many were so advanced in disease, and often so steeped in drink and debauchery, as to preclude all hopes of recovery. During the year 1878 no fewer than 57 persons died within 48 hours after admission. It was not necessary to enter into the general question of giving stimulants in the treatment of disease. A parish infirmary was not the place to begin experiments on the sick poor, as to how little stimulant they could possibly bear.

As long as the present system of medicine was in force—as long as they were taught in their text-books on medicine, and by practice in their hospitals and medical schools, that for certain conditions of disease, alcohol in some form was advisable, nay, necessary—so long was it their duty to use it. Nor was the class of persons whom they got as patients such as to render an innovation of that kind proper or advisable. Several of them were aged people, who had been accustomed for many years to some form of stimulant; and to many of them a little beer or spirit in sickness was not a luxury but a necessity.

The report concluded by stating that in the St. George's Union Infirmary the expenditure of such an unreasonable sum as £8 3s. 6d. for wine, spirits, and beer among 2,496 patients in one year represented a want of consideration for their comforts that amounted almost to hardship, and reflected little credit on the administration. With the ample material at our command, furnished by the numerous union infirmaries in England, it must be possible to arrive at an approximate and truthful estimation of the real value of alcohol in the treatment of pauper patients. We want some honest statistics, furnishing full particulars of the sex, age, occupation, and diseases of the patients; the average number of admissions, and age at death; with an account of the habits of the [illegible] antecedent to admission; and the amount of alcohol [illegible]ed, with an explanation of the principles upon which [illegible]ministered.

FOREIGN DEGREES, AND HOW TO OBTAIN THEM.

The graduating facilities in England are fewer than anywhere else in the world, and hence many young practitioners, who have completed their full curriculum without being able to comply with all the requirements of our British universities, resort to the Continent, and obtain a foreign degree. The diplomas obtained from foreign universities vary in value, some requiring a high standard of education, and a more stringent examination; but, as some of these degrees were conferred without any examination, they were valueless. Lately, foreign universities have refused the granting of degrees *in absentiâ*, or without examination, and, consequently, they have improved in professional estimation.

Our advice must always be for the student to attach himself to a university of repute in the United Kingdom, where he may be able to take his M.B. and M.D., as these will be of much greater assistance towards the attainment of official and Poor-law appointments. Foreign degrees are also almost valueless as stepping stones to appointments at our leading hospitals and medical schools. But to the practitioner, who cannot possibly devote the time necessary for British degrees, and who is anxious to place the magic initials M.D. after his name, either for personal ambition or to gratify the ignorant requirements of a certain section of the public, the foreign universities must *nolens volens* be acknowledged *faute de mieux*. A degree formerly was looked upon as an indication that the possessor was a man who had enjoyed a leisurely education, with unstraightened means, and it was thought that by residence at a university, like Oxford, Cambridge, or Dublin, and by the social contact with highly cultivated and refined minds, the professional aspirant acquired a higher cultus, and obtained a social prestige, which might be afterwards useful in the battle of life.

Unfortunately, this conservative idea seems to be fast disappearing. A M.D. is a M.D. to those people to whom "a primrose by a river's brim a simple primrose is, and nothing more," and whether a degree be obtained from Oxford, Cambridge, London, Dublin, Edinburgh, Paris, Louvain, Berlin, Heidelburg, or Pennsylvania, the public, as a rule, do not choose to ask.

We shall briefly point out the best foreign universities with requirements necessary for examination, and shall also give the best routes, and, in some cases, the probable outlay, both of journey and hotel expenses.

UNIVERSITY OF FRANCE.

Paris. — *Route* from London, *via* Newhaven and Dieppe, per London, Brighton, and South Coast Railway, is much the cheapest and the most pleasant.

The following conditions are necessary for the degree of doctor of medicine of this university:—The Minister of Public Instruction must be communicated with, and certificates showing the course of study undergone by the foreign candidate will have to be submitted to him. If satisfied, authorisation will be granted for the five final examinations for the doctorate.

The candidate must pay fees amounting to about £56 English money, and three months after the payment of all fees the examinations will take place.

Digitized by Google

The examinations are divided as follows—

1. Anatomy and physiology.

2. Internal and external pathology, operative medicine, operations on the dead body.

3. Natural history in relation with medicine, physics and chemistry in relation with medicine, pharmacology.

4. Hygiene, legal medicine, materia medica and therapeutics.

5. Clinical medicine, surgery, and midwifery. The candidates have, moreover, to treat in French, some subject selected from the above.

A thesis must also be written on some subject selected by the candidate, and, moreover, he must verbally develop the subject of his thesis.

It is evident from the foregoing conditions that only those who have some time at their disposal, and who are acquainted with the French language, can undergo these examinations.

This degree of medicine is a high one, and confers on the possessor of it a corresponding status. Students without diplomas who desire to follow out completely the French course of studies will find full particulars in the "Guide aux Etudiants," obtainable in London of the publishers, Baillière, Tindall, and Cox, 20 King William Street, Strand.

THE GERMAN UNIVERSITIES.

The German Empire possesses twenty universities which confer degrees in medicine. They are far from being all equally important and equally frequented; as we may see from the following return of students for the year 1878. (a)

Berlin	260	Konigsberg ...	135
Bonn	140	Leipzig	365
Breslau	170	Marburg	105
Erlangen	100	Munich	341
Freiburg	147	Rostock	36
Gottingen	115	Strasbourg ...	150
Greifswald ...	225	Tübingen ...	220
Halle	110	Wurzburg	434
Heidelberg ...	79	Giessen	
Keil	80	Jena	

There is free trade in medicine in Germany, and quacks can practice, but they do so at their own peril and risk, and are liable not only to civil responsibility, but to penal enactments, for *malpraxis*. There are two forms of diplomas granted, one purely scientific by a university, the other after a state examination, and when the second diploma is obtained the possessor is protected from any civil action in case of malpraxis. Our English law, as we know, is very different from this.

We shall select a few of the German universities—

Berlin. — *Route*, London, Dover, Calais, Brussels, Paderborn, Berlin, Dover, Ostend, Malines, Berlin.

The University of Berlin enjoys a world-wide reputation, and its diploma is recognised as a high-class qualification.

The aspirant must be a good Latin or German scholar, and must be prepared, both practically and scientifically, for a searching examination. The following conditions are necessary—

1. The candidate must prove that he has studied medicine for at least four years at some duly recognised university.

2. He must matriculate, or give proof of matriculation.

3. After the presentation, to the Dean of the university, of the foregoing documents, a written and verbal preliminary examination has to be undergone. Over this the Dean presides alone, and, if satisfactory, permission is given by the Faculty for the next examination.

4. This examination is conducted by six professors, who each examine the candidate for a quarter of an hour on some subject of a theoretical and practical nature. If he passes this ordeal he has—

5. To present, in German or Latin, an original dissertation, on any subject in the whole range of medicine. The MSS. copy is submitted to the Faculty, and, if approved by them, the candidate must have it printed at his own expense, and a certain number of copies must be distributed amongst the professors.

6. The candidate must defend his thesis publicly, and, if satisfactory, the candidate is then promoted to the degree, after taking an oath and paying all fees, amounting altogether to about £22 10s. As a rule, this examination may be undergone in ten or twelve days.

Under exceptional circumstances, the Minister of Education may allow the English language to be used at the public disputation. There are about seventeen medical men in Great Britain who possess the M.D. of Berlin, four of whom are resident in Manchester.

Bonn.—*Route*, London, Calais, Brussels, Cologne, Bonn.

This famous university was founded by Frederick William III., and Bonn is a typical example of a German university town. As it is favoured by the Royal Family for the education of its princes, its degrees are looked upon with favour.

For the diploma in medicine the following conditions must be complied with—

1. Fees, amounting to about £15, must be paid to the Dean.

2. The candidate must undergo an examination in medicine and surgery, in the German language.

3. He must submit an original written scientific dissertation in German or Latin, and publicly defend it.

Erlangen.—*Route*, London, Calais, Brussels, Cologne, Frankfort-on-the-Maine, Wurzburg, Erlangen.

The requirements for the Erlangen degree are evidently more liberal than those of Bonn, for we believe there are about 25 possessors of the degree in England, whilst Bonn has only 2 representatives. The candidate must submit to the Dean the following documents—

1. Proof of preliminary general education.

2. Proof of a regular medical education at some recognised school of medicine.

3. An original scientific medical treatise.

4. He must undergo an examination in all branches of medicine and surgery, in the German language, and if this be satisfactory, after paying all fees, amounting to £15 10s. and delivering 150 copies of his thesis to the Faculty, the degree is granted.

Freiburg.—*Route*, Calais, Brussels, Cologne, Mayence, Carlsruhe; or London, Calais, Paris, Bale.

This university is not so well known or so frequented by English aspirants, though the conditions are easier.

The candidate must pay a fee of £15, give proof of pre-

(a) *Progrès Médical.*

Digitized by Google

liminary and medical education, deliver a written or printed dissertation, and undergo a *viva voce* examination in all branches of medicine and surgery, in the German language.

GIESSEN.—*Route*, London, Dover, Calais, Cologne, Brussels, Denetz.

Judging by the number of medical men in Great Britain who have taken out this degree (about 22), it seems to be a favourite resort.

According to the regulations the candidate is required—

1. To pay a fee of £22 to the Quæstor.
2. To give proof of sufficient preliminary and medical education.
3. To submit a written or printed dissertation on some medical subject, written in either German or Latin.
4. To undergo a *viva voce* examination, of about two or three hours, in all branches of medicine.
5. To present a certain number of copies of the printed dissertation to the Faculty, when the degree is conferred.

GOTTINGEN. — *Route*, London, Calais, Brussels, Aix, Dusseldorff, Paderborn, Kreinsen, Gottingen.

The conditions are somewhat similar to the foregoing as regards essay, language in which examination is conducted, (German or Latin), *viva voce* test, and the fee is £22.

HALLE.—*Route*, London, Calais, Brussels, Paderborn, Norhausen, Halle.

This university has not a single representative in Great Britain; the conditions are somewhat similar to those of the University of Berlin. After complying with the rules as to evidence of education, and paying the fees (about £15), to the Dean, there is an examination held on two consecutive days. After passing which, a scientific treatise must be composed and delivered to the Dean, together with some subject for public discussion. 172 copies of this treatise must be distributed amongst the Faculty, when the candidate undergoes the public ordeal of defending his treatise and his thesis. If this is satisfactory, the doctoral oath is taken, and the diploma is given.

HEIDELBERG.—*Route*, London, Dover, Calais, Brussels, Aix, Cologne, Mayence, Worms, Mannheim.

This old and noted German university evidently suits the convenience of English practitioners, for we find that its diploma is possessed by about 45. The regulations vary a little from those adopted by the other universities, viz., there is no reference required as to past studies, the candidate being examined in all branches of medicine, and tested both *viva voce*, and by the usual treatise. No oath is administered, the Dean simply shakes hands with the successful candidate. The fees amount to £22. Language, either German or Latin.

JENA.—The candidate must matriculate at the university, and give certificates proving course of studies he has undergone. If satisfactory, after paying £22, he is permitted to the examination, which is conducted in German, and includes all the usual subjects in medicine. The other conditions are similar to those at other German universities as regards treatise, public disputation, &c.

KIEL.—*Route*, London, Hamburg, Kiel.

The regulations are simple—

1. There is a certificate required of medical studies, with curriculum, and payment of fees.
2. A scientific treatise.
3. A written examination.
4. A verbal examination. The language is German or Latin.

MARBURG.—The conditions are nearly the same as above, but the cost of diploma is less—£16 10s.

MUNICH. — *Route*, London, Dover, Calais, Brussels, Cologne, Frankfort-on-the-Maine.

This is one of the most famous towns in Germany, and its University enjoys a good reputation. For its degree the following requirements must be fulfilled—

1. The candidate must give proof of a satisfactory general education, and of a regular education of at least four years.
2. He must submit certificates showing that he has practically treated surgical and eye complaints, performed operations on the dead body, and attended midwifery.
3. He must then pass a two hours *viva voce* examination in all the branches of medicine.
4. There is the usual treatise or dissertation in Latin or German, but the printing is not an absolute necessity.
5. He must pay the fees, amounting to £15.

ROSTOCK.—*Route*, London, Hamburg, Lubeck, Rostock.

The requirements are as follows—

1. Certificates of a regular course of study, and of examination by some licensing body.
2. An original treatise, which must be printed, and of which 126 copies must be distributed.
3. A public defence of the essay.
4. Payment of £16 10s.

STRASBURG.—As is well known, Strasburg once belonged to France, the present university only dating from 1872. The language now used being German, the conditions are the same as those of Marburg, the fee being £15.

TUBINGEN.—This is a well-known university, and its degree is granted on the following conditions—

1. The candidate must send with his application a fee of £15, and produce certificates showing proficiency in medical and general education.
2. He must undergo a written examination in all the branches of medicine, and subsequently a *viva voce* examination.
3. He must compose a dissertation, 250 copies of which must be presented to the University. Authors who have already published may receive a dispensation from this test.

WURZBURG.—*Route*, Dover, Calais, Brussels, Cologne, Mayence, Frankfort-on-the-Maine, Wurzburg.

The regulations are slightly different for the degrees of this university.

1. The candidate must submit certificates as to character and course of study.
2. He must pay the fee of £15.
3. He must compose a scientific work, to be reported on by one of the examining professors.
4. If satisfactory, the candidate is examined orally in the various branches of medicine.

The requirements of all the other univerities are nearly

Digitized by Google

similar to the foregoing, and we need not consequently give them in detail.

The leading feature of the German examination consists in the written examination, tested by means of a printed treatise which has to be publicly defended. This system necessarily leads to the production of a large number of pamphlets or essays, of which we may safely say with Martial—

Sunt bona, sunt quædam mediocria, sunt mala plura quæ legis.

In connection with German Universities are very large libraries. Thus, Munich possesses 500,000 volumes; Bonn, 150,000; Göttingen, 400,000; Strasburg, 200,000; Freiburg, 250,000; Giessen, 140,000; and Halle, 100,000. We need hardly wonder at the richness of the literature if the dissertation of every student finds a place on the bookshelves.

Another feature is, that candidates are examined in the language of the country, and hence an acquaintance with German and German medical literature is essential.

At one time German degrees were obtained *in absentia*, and there were agents in England who purchased for their clients, at fancy prices, worthless sheets of parchment. We are happy to say that this system has been put an end to, and we applauded in the *Medical Press and Circular*, Oct. 2, 1878, the action taken by the Dean of Tübingen, in reference to the granting of degrees *in absentia*.

German degrees may now be considered *bona fide* qualifications, and we trust the various Deans of the Faculties of Medicine will preserve the character of their universities, by faithfully adhering to their regulations, and by insisting on each candidate complying in full with their laws.

UNIVERSITIES OF AUSTRIA-HUNGARY.

In the Austria-Hungarian Empire there are nine universities possessing faculties in medicine and granting diplomas—viz.—

Agram.	Pesth.
Gratz.	Prague.
Inspruck.	Salzburg
Cracovia.	Vienna.
Lemberg.	

Candidates for the degree of doctor in medicine must undergo three examinations.

For the first examination the candidate must prove—

(*a*) That he has received a satisfactory preliminary education.

(*b*) That he has dissected for two sessions and attended the course of the faculty for four sessions.

(*c*) That he has undergone, before a university, an examination in botany, zoology, and mineralogy.

For the second examination he must have studied for five years and followed for four sessions the cliniques in medicine and surgery, and attended, for one session at least, a course of ophthalmology and midwifery.

The third examination comprises a theoretical and practical part. It takes place in presence of a Government official, and one examiner is nominated by the Government.

The expenses of the examinations are about £25.

The University of Vienna enjoys a good reputation, possessing a staff of 56 professors and 70 unattached professors.

Vienna is one of the handsomest cities in Europe, and is famous for the beauty of its public buildings. Some of the cliniques are famous.

UNIVERSITIES OF SWITZERLAND.

Switzerland possesses four universities—viz.—Bale, Berne, Geneva, and Zurich.

BALE.—*Route*, London, Paris, Troyes, Chaumont, Mulhouse.

The conditions for this degree are so national that few English practitioners would think of fulfilling them, as they require matriculation and attendance on a course of lectures at some of the Swiss schools, though the other regulations are somewhat similar to those adopted by the German universities.

BERNE.—*Route*, London, Paris, Dijon, Neufchatel, Berne.

This university, we believe, looks favourably on lady doctors, and hence we find some English ladies have resorted to it for a degree in medicine, especially as the conditions are comparatively easy of fulfilment. The examination is conducted in either French or German, and the candidate must undergo a written and oral examination. The written portion comprises a manuscript treatise, and the oral, a three or four hours' examination in all the branches of medicine and surgery.

GENEVA.—The Geneva faculty is also very liberal in its requirements, whilst the fee is extremely small. The following conditions are required—

1. The candidate must pay a fee of 40 frs., and give proof that he is either a bachelor of science, or that he has undergone some equivalent examination.

2. He must undergo an examination divided into five portions—

(*a*) Anatomy, physiology, histology, pathological anatomy, general pathology, an autopsy (for which one hour is allowed), and an anatomical preparation (for which four hours are allowed).

(*b*) Internal pathology, external pathology, operative medicine, three operations, and the application of bandages.

(*c*) Hygiene, therapeutics, materia medica, pharmacology, legal medicine, a medico-legal report upon a case given.

(*d*) Examination of two complaints of internal clinical medicine, examination of two complaints of external clinical medicine, examination of a case of midwifery. For each case fifteen minutes are allowed. Operative midwifery on the "mannequin." Discussions upon each of the foregoing cases: Written essay about one case of external, and one of internal, clinical medicine, for which two hours are allowed.

(*e*) Defence of a dissertation in the French language upon any subject of medical science chosen by the candidate, and which has been previously communicated to the Faculty; on the completion of which a further fee of 100 frs. has to be paid.

ZURICH also looks favourably on the cause of women-doctors, and as we mentioned in the *Medical Press and*

Digitized by Google

Circular, Aug. 6, 1879, Prof. Hermann has a lady for his assistant in physiology, whilst Prof. Rose does not disclaim similar assistance in his *rôle* of surgery; so that the lady students of St. Mary's need not have any fear of turning their steps to this famous university.

The conditions are, however, stricter than those of Berne or Geneva. The candidate must apply to the Dean, enclosing certificates of attendance, on lectures on chemistry, physics, botany, zoology, and a dissertation. If required, the treatise must be printed.

The first examination is written, and the candidate has to answer questions on anatomy, physiology, pathology, therapeutics, surgery, and midwifery. The *viva voca* examination extends over the other branches of medicine.

The next step consists in sending 200 copies of the dissertation to the university, and undergoing a public examination on some thesis submitted by the candidate.

The fees amount to 360 francs.

UNIVERSITIES OF ITALY.

Degrees are granted by the Universities of Bologna, Catania, Padua, Palermo, Pavia, Pisa, Rome, Sienna, and Turin. The language used is either Latin or Italian, and the conditions of all the universities are somewhat similar to those of the University of France.

UNIVERSITIES OF BELGIUM.

Belgium possesses three Universities, Brussels, Liège, and Louvain.

BRUSSELS.—*Route*, London, Dover, Calais, Brussels.

This university seems to offer to English practitioners every facility for obtaining its degrees, and there has been for the last few years a regular exodus from England to its examinations. It is quite evident that there is a great desire on the part of medical men who are settled in practice, and who have English licenses in surgery or medicine, to obtain the degree of M.D., and it is well-worthy of consideration, whether some facility should be afforded by our English universities to meet this want, or England will be flooded with Belgium M.D.'s.

At the annual meeting of the South-Eastern Branch of the British Medical Association, Dr. Robert Bowles, President of the Branch, has exhaustively treated the subject (vide *British Medical Journal*, Aug. 2, 1879), and we need not dilate upon it. The regulations of the University of Brussels are as follows—

1. The examinations are conducted in English or in French, and extend nearly over one week.

Candidates must attend in person, and subscribe their names after exhibiting their qualifications or diplomas. After paying a fee of £21 4s., the candidate must undergo three examinations as follows—

(*a*) General therapeutics, including pharmacy, dynamics (proportion of doses), special pathology and therapeutics of internal diseases, general pathology, and pathological anatomy.

(*b*) Surgical pathology, theory of midwifery, public and private hygiene, medical jurisprudence (forensic medicine).

(*c*) Examination, at the hospital, of one or two patients under medical and surgical treatment; examination in midwifery, consisting in obstretrical operations on the mannequin (model of pelvis); examination in operative surgery, consisting in some of the usual operations on the dead subject, such as amputattion, ligature of an artery, &c.

Before starting for Belgium the candidate should write to the Dean of the Faculty to make arrangements as to the time of examination.

LIEGE.—Liège has not yet adopted the lesson in political economy, taught by its sister at Brussels, the law of supply and demand for the making of honest money.

Its degree can only be obtained after passing three examinations in French as follows—

1. General chemistry, logic, moral philosophy, experimental physics, psychology, elements of zoology, botany, geology, and mineralogy.

2. Elements of comparative anatomy, descriptive and regional anatomy, human physiology, and pharmacologia.

3. General pathology, pathological anatomy, special pathology and therapeutics, mental maladies, general therapeutics, surgical pathology and ophthalmoscopy, theory and practice of midwifery (including operations), public hygiene, legal medicine, clinical medicine, clinical surgery, surgical operations. The fee is only £15.

LOUVAIN.—Louvain is the seat of one of the most once-famed university in Europe, which numbered its students by thousands. It has always been distinguished by its perfect orthodoxy. For its degrees there are two stages—that of candidate and that of doctor. For the first, two years of study is required, and the possession of the title of candidate in science before an examination is undergone; and for the second, an additional two years, and proof of having passed the first stage.

The examinations are held in French, and embrace the natural sciences and all the branches of medicine. There is also a thesis or dissertation required, which must be publicly defended either in French or Latin.

The total fees amount to about £12 in English money.

FARES BY THE DIFFERENT ROUTES.—The following through tickets are issued by Messrs. Thomas Cooke, and Sons, at their Tourist Agency Office in London, and the principal large cities in the United Kingdom :—

STATION.	ROUTE FROM LONDON.	FARES OF RETURN TICKETS. THIRTY DAYS.

WEDNESDAY, OCTOBER 1, 1879.

MEDICAL EDUCATION.

AT the present a number of teachers of some branch of medical study are preparing or delivering opening addresses at the different schools of medicine—metropolitan and provincial. In discussing the subject of medical education we do not desire to be supposed to dictate to them what subjects they should discuss; but rather we wish to suggest some matters for their consideration. A medical education is a matter of considerable moment from various points of view.

In the first place, most medical students are the children of persons who cannot afford the money to first give them a university education; and then a special medical education. Their means will only admit of a certain expenditure; and the medical curriculum perhaps entails a good deal of self-denial on the part of the family of the student. Then there is the public, of whom some, sooner or later, will have to come under the treatment of each student, and who will be the better or the worse for his knowledge or want of it. For after all, the treatment of disease, and the alleviation of suffering are the great ends of a doctor; the prevention of disease being really the duty of the public to themselves, and yet they throw all the burden of trouble on their medical men, and obstruct and thwart their health officers as much as they can. Whether it is cheaper to have disease, death, and doctors' bills, than to wash and be clean, is a matter which fortunately we are not called upon to decide. A patient does not call in a medical man in order that the latter may have the opportunity of observing the interesting details of his malady. He likes to see pains taken in his examination, and feels that this is the proper way in which to arrive at an exact knowledge of his ailment; but after all, his great aim is to seek cure or relief. In return for his money he wishes to get something which he can regard as "value received." How often he gets nothing of the kind—in fact, how often it would have been wiser to throw the money into a river, and leave his trouble to Nature's curative powers; it would be invidious to say. The question may be asked, Is the present form of medical education the best possible to enable a student to be of service to his fellow men? The gravest possible doubts may be entertained on this subject!

Of course the teacher's duty, to his pupil and his school alike, is to enable his pupil to pass the requisite examinations for the acquiring of a diploma. And the object held up to the student's gaze almost invariably is the "pass." Whether he possesses any real information which will be of service to his fellow creatures or not, the examiners are supposed to find out. And a pretty extensive acquaintance with medical men puts us in a position to say that there are, in the ranks of our profession, a considerable number of men who are simply frauds. They may have got up their anatomy well; and prepared themselves for the performance of grave surgical operations, which not one in a hundred will ever have the opportunity of performing, and not one in a thousand is fit to perform when the opportunity comes to him—as all the anatomical minutiæ requisite for its successful performance have long since passed out of his memory. He is taught to know the points which indicate a cavity in the lung; but it may be doubted if he is ever taught to look at the phthisical patient's tongue, or to investigate the condition of his assimilative organs, on which, however, the future of the case essentially turns. He is instructed how to boil urine in a test tube, but neither he nor his teachers can, in many instances, tell whether the albumen, when found, is the indication of serious disease, or a mere fact of little or no importance. Again, he finds sugar in the urine, and proceeds at once to diet the patient, and sometimes nearly kills him as the consequence of the treatment adopted: as occurred in one case at least which came under our notice lately, and where the patient had to take back to a farinaceous and saccharine dietary to save his life—and on which for twelve years he has been well and active, though his urine contains sugar to an extent which is unprecedented in our experience, and almost incredible. He is taught to wield a clinical thermometer; but, a sa rule, he is utterly unenlightened as to the proper treatment of pyrexia with a moist skin, and a dry skin; and yet there is an essential difference in the two. In fact, he is crammed to pass an examination, not educated to think and reason about actual disease; and he leaves his college with a diploma in his pocket; and learns something of disease at the bedside, and at the expense of the people who are so unfortunate as to be his first patients. He thinks he knows everything; and is too profoundly ignorant to have any rational conception of how very little he does actually know: and would not thank anybody to undeceive him.

Digitized by Google

He is often about as complete a fraud as can well be imagined.

And yet the Anglo-Saxon race is eminently practical; and has, as Kingsley puts it, "a strange willingness to learn." How comes then so unfortunate, so deplorable a result? It is evident that there is something radically wrong somewhere. Are the examiners indifferent, or incapable of testing a man's information? it may be asked, but *quis custodiet ipsos custodes!* It may be questioned very gravely, whether the time occupied by a medical education is spent to the greatest advantage or not; whether the student is taught the kind of information best calculated to be of service to him and others in his chosen vocation? Students often bitterly complain that they cannot see of what avail certain knowledge, which they must get up for a pass, is to be to them in after life. They would give their minds far more thoroughly to their studies if it could be demonstrated to them how they will bear on actual practice. Who but an anatomical teacher ever remembers how many bones there are in the wrist, except it be the surgeon who is about to perform an operation on that joint; to say nothing of being able to discriminate them from each other, after he has been five years in practice. Who ever remembers about the annulus of Vieussens, or ever learns anything about it afterwards? unless his physiological inquiries have interested him in the relations of the vaso-motor nerves of the liver to the occipital portion of the cerebrum supplied with blood by the vertebral arteries. What student has ever been taught to look at the chemical composition of the bile acids as indicating their origin in the albuminoids of our food; and the practical value of this knowledge in the treatment of biliousness? Students have to grind up the anatomy of the sympathetic nerve; but how many are ever taught to discriminate betwixt primary gastric dyspepsia and the far more common reflex form which is caused by irritation in the ovary, or displacement of the uterus: and yet how such information would stimulate them in their anatomical studies! He is familiar with the fact that vomiting is common in the early months of pregnancy; perhaps he has had pointed out to him in the wards of the hospital, that severe vomiting is a common symptom of calculus in the kidney; but who has ever thought of giving him definite ideas about reflex disturbances generally? No one! Not a syllable does he ever hear about reflex disturbances. The still waters of his mind are never disturbed by any suggestion that in far-away irritation will he often find the first departure from health in many of the maladies he is most commonly called upon to treat.

And, of course, his treatment is simple blundering, which interests the patient, makes a bill, it is to be feared, but that is all. He is taught much about physical signs—can detect a cavity—or more probably persuade himself he can, and a moist râle here and there; but he is profoundly ignorant how to approach the treatment of a case of early phthisis; nor is he ever reminded by the composition of perspiration of the importance of checking the "night sweats" which drain the body of its salts. He is taught to detect a cardiac murmur; but how to appraise its significance he has no more idea than had the Zulu at Rorke's Drift, who thought he was all safe when he held on to the muzzle of a rifle, of the mechanism of the breech loader which blew out his confiding brains. He is launched into practice about as dangerous a member of society as can well be conceived: an ignorant solicitor may cause his client much pecuniary loss, but an ignorant medical man my kill his patient outright. How much time is devoted to dissection; and how little to the study of physiology? A man is kept dissecting for three winters, who may pass his lifetime in harness without ever being called upon to cut down and tie an artery. Yet every day of his life he has cases which call for some accurate notions about the functions of the liver, and the assimilation and destination of the albuminoids after they have been swallowed; and yet, how many of the men who every year are passed into the ranks of the profession, or rather how few, have a rational idea on the subject? What is taught in an educational course is something which will be of value in after-life: or something which is valuable as training the mind, as educating the intellect to inquire and instruct itself on other topics. The mathematical knowledge insisted upon at the two great English universities is of itself of value to but a very small percentage of graduates; but it is insisted upon that it is a useful matter for training the youthful mind. Well, we do not deny that it may so be useful; but we do feel inclined to ask if some other knowledge could not be substituted for it, which would be equally useful for the training of the mind; and which might be of more value in after life. The question of useful knowledge has been recently entertained by Mr. Henry Power, in his opening address in the Physiological Section of the British Medical Association, at its recent annual meeting at Cork, in reference to medical education. What he has to say is entitled to the greatest respect; and what he says is put in an incisive manner. We quote it in full: "No doubt can be entertained that a better and more thorough knowledge of physiology should be possessed by the younger members of our profession than at present prevails. In my opinion, and I have had large opportunities of observation, I think, that considering the time at the disposal of the student, too many anatomical details are required in most examinations; whilst physiological knowledge is not only essential for the due and safe practice of the profession, but that it is a very important means of education: that it is the one thing which is properly taught; the one thing that is well known in the preparation for the medical profession. Whilst admitting its value in this respect, and acknowledging the difficulty of drawing any hard and fast line defining what should and should not be known, I cannot but think that the candidates for most of our examinations are asked points in anatomy which, when known, are utterly valueless; whilst if the same time and labour had been bestowed upon physiology, valuable information of a practical nature would have been acquired. Many candidates for our ordinary examinations are able to describe the course and relations of minute branches of nerves and arteries, a knowledge of which they will most probably never have any occasion to apply, or, if they have, they will have forgotten them; whilst in regard to such important practical points as the nature and digestibility of different kinds of foods, or the more important phenomena of the circulation and respira-

Digitized by Google

tion, they can give no intelligible account." And yet it would appear that a competent knowledge of the circulation, and of arterial tension, for instance, would be of service every day in the practitioner's work of life; while the relations of minute arterial twigs can only be of service to him on the rarest possible occasions. It is in so far that physiology makes anatomical knowledge useful, that the chief utility of the latter lies. Without physiological knowledge anatomy is only useful from its regional aspect, that is surgically or diagnostically in examining the viscera, or following out neuralgia. It is the light which physiological investigation is throwing upon anatomical details, that is giving them importance and practical value to the student; provided he is instructed with regard to the requirements of actual practice.

THE DUBLIN SANITARY COMMISSION.

THE long-promised inquiry into Dublin sanitation was to have commenced its sitting yesterday (Tuesday), nearly a year and a-half having elapsed since the Chief Secretary gave the promise that the investigation should take place, and many months having gone by since the commission was actually appointed. The public announcement sets forth that—

Mr. Robert Rawlinson, C.B., Chief Engineering Inspector to the Local Government Board, and Dr. Frederick Xavier MacCabe, Inspector to the Local Government Board for Ireland, have been appointed her Majesty's Commissioners, "empowered and authorised to make and institute an inquiry touching and concerning the present system of sewerage and drainage in the city of Dublin, in so far as such sewerage and drainage affect the sanitary condition of the said city, and the state of the river Liffey which flows therein, and to inquire whether such system is directly or indirectly prejudicial to the public health, and whether any and what changes are necessary therein, with a view to sanitary improvement."

We have, of course, no feeling other than satisfaction that the Government has, even so tardily, yielded to the public demand for this inquiry, and we have complete confidence that the gentlemen who have been nominated as judges will, "without fear, favour, affection, or envy," give expression to what they believe to be the exact truth of the matter, and do their best to ascertain where that truth lies.

We must, however, at once, express our dissatisfaction at the terms in which the advertisement of the inquiry is framed, and our apprehension lest, after all, its results may be absolutely valueless as an explanation of the unwholesomeness of Dublin. We are told by the announcement that the committee is "to institute inquiry touching the present system of sewerage and drainage in so far as such sewerage and drainage affect the sanitary condition of said city . . . and whether any and what changes are necessary therein, with a view to sanitary improvement." On the other hand, we hear it said that the commission is at liberty to hear evidence respecting any and all of the causes of the unhealthiness of Dublin. If the latter be true we are satisfied, and we strenuously urge the Sanitary Association to be up and stirring, and to bring before the notice of the commissioners without delay the overwhelming proofs which are at hand that simple dirt and universal disregard of sanitary law are the principal and actual causes of the great mortality within the city. But, if we are justified in our apprehension that the commission is to hold an engineering inquiry into the cleansing of the Liffey and the cost of it, we at once protest that such an investigation will be totally unsatisfactory, will be of little use, and will give confidence to no one. Every one who knows anything of the sanitary condition of Dublin—even the Public Health Committee of the corporation itself and its officers—knows well that the lower classes of Dublin die as they do because they live from their first breath to their last in abominable dens, unfit for swine, from which wealthy tenement-farmers make large profits, by never spending on sanitary improvement a shilling they can help. Every one believes that, if the death-rate of Dublin is ever to come down, it must be brought down by a thorough overhauling of these places by a really active and earnest house-to-house examination of them, and by a rigid and impartial enforcement of the law, not only against the miserable tenants, but against the well-to-do and influential owners. What we need from a commission is an authoritative declaration whether or not this is so; and if they have no power to make the requisite inquiry, or to give expression to an opinion on this subject, they might as well never have been appointed.

Are the commissioners aware that in the past week the death-rate of Dublin was 24·3 per 1,000 of the population, while that of smoky, overcrowded Glasgow was 16·6; that it was largely in excess of the ten years average of Dublin city; that the number of new admissions to hospital for small-pox was 42, being 25 above the number for the previous week! Have the commissioners read the following public statement from Mr. Exham, Q.C., the Magistrate of the South Dublin Police District:—

He (Mr. Exham) considered it his duty to go and see the place himself. Having inspected the premises, he now stated it was a perfect disgrace to any civilised city, and if there are many houses in a similar condition he did not wonder at the death-rate of Dublin being so high He believed were he to stand in the hall for half-an-hour he would become sick. The ceilings were all in smash, and had evidently been so for years; broken panes of glass were numerous, but this was probably fortunate for the wretched tenants as a means of ventilation, when he remembered the foul, obnoxious smell that came from the yard, and indeed from portions of the house itself. The skirtings one would expect to find at the stairs are broken away; and in ascending the stairs, a foul and filthy mass of liquid matter is observable within the four walls of the house. The sergeant begged him not to enter the yard, or to go up stairs, he assumed because they were in a terrible condition, and as the owner did not invite him to inspect them, he did not do so. He assumed that the owner had no objection to receive rents for this abominable hole, and he now stated publicly it was unfit to contain a single human being for one night.

We assert, without fear of proof to the contrary, that not a few, but a large proportion, of the houses in which the Dublin poor live are no whit better than this; and that they have remained so, and unless the Commission does something, are likely to remain so as long as there is no more effective check upon tenement-farming than that of the corporation.

It is but a few days since that one of these places fell down from their rottenness, and we hear that since then a number of others have been condemned, and yet these

Digitized by Google

houses remained under the toleration of the corporatiou and its officials, and might have remained for ever if the laws of Nature did not prevent their continuance.

While these things are so we assert that, if the commissioners could make the Liffey a limpid brook, and its bed a spotless rivulet, they would do nothing real towards a remedy for Dublin insanitation, and we can see no better result of their labour than to saddle the citizens with the payment of half a million of money, and to make the fortunes of half-a-dozen contractors.

Notes on Current Topics.

Baby Murder.

The frequent recurrence of the horrors typified most recently by the Tranmere baby-farming case indicates the necessity that exists for some prompt and energetic action that will have for its result the prevention of such crimes as this last one. There are about the Banks' performances so many professional details of exceptionally revolting kind, that it has served more than any other recent exposure to stir a general feeling of determination to do once for all what shall prove deterrent to intending successors in the same line. It cannot be doubted that at the very best, and putting the matter in the mildest possible light, whoever accepts the charge of a number of infants, and knowingly and wilfully neglects to afford them so much nourishment, and of such kind as they require to be supplied with, is thereby consciously acting detrimentally to the welfare of the infant. And when, as in the case of the two unfortunate infants who have succumbed at Tranmere, death sooner or later supervenes on the continued course of neglect and insufficient food, it can never be questioned that murder, wilful murder, and murder of a dastard sort has been wittingly committed. The medical man who countenances practices inimical to the well-being, be it only of an infant life, is, moreover, culpably in fault with the actual perpetrator of the crime; and we fail to see any excuse that can be urged to defend any registered practitioner who, at the first suggestion of wrongful treatment of children, many, or few, omits to take such measures as are in his power to stop the further infliction of hideous cruelty. No child, soever, can be buried unless the death certificate, duly signed, be produced. This simple measure should, in our opinion, be enough in itself to render impossible the continuance of baby-farming atrocities. This not being so, the mode in which the regulations relating to the filling and granting of death-certificates are carried out, calls for interrogation, and the inspection ought at once, in the interests of justice, to be made.

Poisoned Sweets.

One might almost think that the age in which people submitted unmurmuringly to be poisoned to death by the attractive coloured sweets and sweetmeats had gone by. Such, however, would seem not to be the case, the South Shield's magistrates having had before them, on Friday last, a confectioner on whom, for selling sweets coloured with chromate of lead, they felt themselves constrained to pass sentence of two month's imprisonment, or a fine of £5. It is not so very long since the first agitation against poisoned toffy was set afoot; and many may remember that Dr. Thorpe, then Assistant Lecturer on Chemistry at Anderson's University, made frequent sallies into the "tuck" shops in search of the poison-bearing "goodies." More, however, than we think, fall victims to the by no means uncommon use of lead bichromate in sugar-boiling establishments; and many general practitioners, puzzled to assign any adequate cause for the symptoms exhibited by their younger patients, will often do well to make very searching inquiries as to the amount and nature of the sweets consumed within the twenty-and-four hours preceding his professional call. It is worthy of note that the *Northern Evening Express*, reporting the case, carefully adds that chromate of lead *was* a poison on the medical authority of Dr. Spear.

Broken Pledges.

Those who expected much from a Government programme, which proclaimed sanitary legislation as one of its leading features, have doubtless, by this, been grievously disappointed, and we have repeatedly had to dwell on the vaccillating policy which has marked the English Local Government Board in its dealings with sanitary reform and sanitary authorities.

In our issue of Sept. 10, 1879, under the heading "An Incredible Story," we narrated a mass of facts illustrating the want of comprehensive management showed by the Local Government Board, and we have again to point out the faults of our central sanitary authority.

When combined sanitary districts were first formed, we hoped that the country would be mapped out into large areas under the sanitary supervision of medical officers of health, who would be unfettered in their action, fearless and independent, and who would thus be in a position to carry out true sanitary reform.

It is needless to repeat the advantages of having combined districts; but the English Local Government Board do not seem to appreciate the importance of preserving existing combinations, or of extending their influence, or rather their compulsory powers, in preventing the disintegration of the only efficient means by which sanitary laws can be enforced. Another instance has just cropped up.

Dr. Cornelius Fox is known as an active, earnest, and intelligent pioneer in the work of sanitary reform. Through his efficiency he has become a martyr; for the combined district to which he was medical officer, has not preserved its integrity, and one of the districts has seceded for the ostensible reason of economy, but in reality, to get rid of an officer who was determined that if drainage was defective it should be remedied, that if the sanitary surroundings of the villages in the Billericay Rural Sanitary Authority were imperfect, they should be made perfect, or in other words, that he would make his office not a sinecure, or a sham, but a reality.

Dr. Fox has resigned, in preference to continuing with a diminished salary and a diminished district, as he felt that he was not supported by the Local Government Board, and that, unless he were willing to hold his appointment, subject to the caprice of

Digitized by Google

the members of his Local Boards, he could not, with dignity or conscientiously, discharge his duties. Dr. Fox is thus a martyr to principle. The resignation of his appointment must entail pecuniary loss, and he will have to return to routine practice again, from which he was attracted by the professions of the Government, in the hope that there would be fixity of tenure, for all efficient medical officers of health who held large combined districts.

The sanitary service attracted a number of able men, most of whom have been deceived. It is the old, old, story, "Put not your trust in Princes," or in the heads of departments. The War Office has taught the profession a lesson, by which it has profited; candidates will not enter now. The sanitary service is being taught another lesson, *væ victis*.

The Lost Art of Prescribing.

PRESCRIBING as an art seems to be on the decline, and the reasons for this, probably are, that students are either not taught the principles, or that routine or pocket formulæ are much more convenient, whilst patent medicines offer a simple substitute for original prescribing. In nearly all modern works on medicine, there is, at the end, a copious formulary from which prescriptions can be selected, thus saving the expense of thinking, of arrangement, and even a knowledge of materia medica, and should the practitioner not be satisfied with these formulas, he can resort to Naphey's "Modern Medical Therapeutics," or Beasley's "Pocket Formulary" for a further selection.

Given a certain disease, there is to hand a ready-made formula; the trouble of thinking is even saved. Patent medicines, as Eno's fruit salt, Freidrichshall, Hunyadi-János, pearl-coated pills, concentrated mixtures, &c., &c., are also destructive of the art of prescribing. We know that physicians in large practice, have recourse to patent medicines, and in place of ordering or writing out a long prescription, they save time, and encourage the patent medicine trade, by advising the use of such and such an article.

Any chemist in large towns, doing an extensive compounding practice, will confirm this statement. It is a matter of regret that the materia medica professorship is not considered of more importance, and that the majority of students leave College ignorant of the art of prescribing.

Hard Times.

FROM every part of the United Kingdom we hear news of stagnation in trade, and, consequent upon this, lower wages and hardship pressing upon every class of society. The landlord cannot get his rents because the farmer is unable to make his land pay; the manufacturer cannot run his mills except at a loss, and in many cases either stops his machinery or runs half time, thus directly affecting his operatives; the professional man who lives by the other money-earning classes cannot obtain a settlement of his accounts, and we have a long chain of cause and effect springing from bad trade. When wages were high, when trade was good, and the country in the highest state of prosperity, the doctor's bill was always the last to be paid, and the long period of credit given by the majority of practitioners fostered the idea that medical men, as they had such large profits, could afford to wait for their money. Now that trade is bad, medical men are suffering very severely, and in many towns there is a positive difficulty amongst practitioners who are doing large practices, to make even ends meet. Patients are as numerous as ever, population goes on increasing, despite of financial difficulties, but money is scarce.

Who is to blame? The answer is a difficult one. The operative might have saved more from the high wages he received in better times, and medical practitioners would also have been better off, if they had insisted on shorter terms of payment, and not given such long credit. We are waiting for the lifting of the cloud, also hoping that hard times will teach a salutary lesson.

Holiday Time for English Poor-law Medical Officers.

WE do not know of any section of the profession who are more deserving of rest from their labours, or who require a holiday more than our over-worked poor-law medical officers, and we are quite certain that it is to the interests of their patients that their medical officers should, for a time, have change of air and scene. As a rule, we believe there is in England no difficulty about leave of absence, the custom being for the medical officer to notify his intention of taking a holiday, and to find at his own expense a legally qualified deputy.

We notice in the *South London Press*, September 13, 1879, a little paragraph written, certainly not in the spirit in which the lay press, as a rule, writes about medical men—and evidently the work of some one unacquainted with the usual routine adopted by medical officers who want a holiday.

We cannot object to such paragraphs any more than we can object to the buzzing of a gadfly, and though they may be annoying to those immediately concerned, the better plan in such cases is to take no notice of them. In the present instance the medical officer in question, Dr. Kelly, wrote to the St. Olave's Guardians informing them of his intended absence of a couple of weeks, naming at the same time his customary substitute, and receiving no reply either of dissent or approval, he thought he might fairly leave his patients in the hands of his deputy.

According to the *South London Press* he is accused of taking "French leave," and it is said that the guardians do not like this, and a query is put—probably intended as a joke—"Did they ask Dr. Kelly to turn over a new leave?"

Now we interpret this in another way. We hope the St. Olave's Guardians will grant their hard-worked and useful medical officer a new *leave*, and find *at their own expense* a deputy for him whilst he is away.

THE following epigram on Professor Allman's Presidential Address is credited to Mr. Evans, F.R.S.:—

From life to consciousness the chasm
Cannot be bridged by protoplasm.
All flesh is grass, but chlorophyll
Can all man's duties not fulfill.

The Dublin Orthopædic Hospital.

Several correspondents have indignantly called our attention to newspaper articles published recently in the Dublin papers in reference to this institution; to the never-ending recurrence of these effusions, to the interlarding of them with details of the astonishing feats of surgery said to be performed therein, and finally, to a long letter from a "grateful patient," gushingly laudatory of a surgeon connected with the institution, whom the writer names. We are solemnly assured that the surgeon referred to had neither cognisance nor part in this publication, and we therefore withhold the censure which such a method of notoriety would deserve if approved by any professional man. We are, however, bound, in deference to the call of our correspondents, to say that in our opinion the puffing of this institution has in Dublin come to be a nuisance and a scandal, that it has outstepped all the necessities of the charity and all the proprieties of hospital etiquette, and, if persisted in, will deprive the Dublin Orthopædic Hospital of all claim on the sympathy of the profession. Moreover, we do not think that medical officers of an hospital who would remain silent and inactive under the free use of their names and their surgical achievements by lecturers, ladies' committees, or penny-a-liners, and who might omit to make their disapproval fully understood, would be doing all the profession expects to disassociate themselves from such bare faced puffery. We certainly expect that the medical staff of this hospital will not again permit the managers of the concern to tout for public sympathy on the strength of their names and their professional standing.

Dublin Inquests.

The proceedings of the Dublin Coroners' Court must have become somewhat notorious through the agency of our columns. We have had occasion to notice, from time to time, the illegal system of paying salary to a medical witness, the salary job perpetrated by the Corporation in favour of the present coroner, and recently, the proceedings of that functionary on the occasion of the inquest on Mr. Michæl Angelo Hayes. A report of an inquest on the body of a man, who died in the Dublin police office while waiting to be sworn as a dangerous lunatic, again calls on us for public notice. The post-mortem examination revealed that the case was one of meningitis, whether alcoholic or not remains to be shown.

Our criticism is, that the coroner, Dr. Whyte, considered it consistent with his judicial functions to act as public prosecutor of the hospital porter who was in charge of the deceased, and of the surgeon who had sent him out of hospital, and that the coroner occupied the greater part of the sitting in the endeavour to force his views into the heads of the jury, and to catch evidence in support of them from the witnesses.

When the surgeon who had been in charge of the case presented himself voluntarily, the coroner refused or omitted to call him as a witness or to put him on his oath, and the testimony of this, the most important witness, as to the cause of death, was received as an unsworn statement, for which there was no legal verification. We cannot give space to the further details of this investigation (?) but refer those of our readers who desire to know more of the matter to the *Irish Times* of September 23rd. We refer to the subject solely in order to record our opinion that it is the business of a coroner impartially to investigate the causes of a death, and to endeavour to control his own preconceptions on the subject; that in the discharge of that duty it is his business to call every witness who may be able to instruct the jury as to the cause of death; and that it is distinctly *not* his function either to bully witnesses into an apparent support of his own theory, or to permit the most important testimony to be put to the jury as a voluntary and irresponsible statement.

The Appointment of Dr. Grimshaw as Registrar-General for Ireland.

At a meeting of the Executive of the Irish Medical Association, held on Tuesday, the 16th of September, at the Royal College of Surgeons, Dublin, Dr. Speedy, Chairman of the Council, in the Chair, it was moved by Dr. J. W. Moore, seconded by Dr. Pollock, and unanimously resolved—"That the Council of the Irish Medical Association have heard with the liveliest satisfaction of the appointment of Dr. T. W. Grimshaw as Registrar-General for Ireland, and hereby convey to him this expression of their gratification at his well-merited promotion to such a responsible and important position under Her Majesty's Government."

At the same time the Council feel much regret in accepting the unavoidable resignation of Dr. Grimshaw as a member of the Executive of the Association, and desire to express their grateful thanks to him for his inestimable and unwearying services to the Association, and to the profession at large.

Liverpool Seamen's Dispensary.

From an interesting article in the *Nautical Magazine* entitled "Our Sick Seamen Abroad and at Home," we learn that this useful dispensary is doing good work. It was established by the Committee of the Liverpool Sailors' Home for the purpose of providing seamen with medical attendance and medicines at the lowest cost, "and thus protecting them from the numerous advertising quacks who infest Liverpool as well as most large towns." It has now been in full working order for two years and a half, during which time it has given relief to 2,310 patients. The practice of the dispensary has been from the first limited to venereal diseases, as not only is the provision made in Liverpool for the treatment of these complaints very inadequate, but sailors don't like attending at general dispensaries where they are kept waiting in the company of women and children. Hence this dispensary supplied a great want, and we hope with the writer of the article referred to, that similar institutions will spring up wherever they are likely to be useful.

The Ennystimon (co. Clare) Board of Guardians have decided to reduce the salary of their sanitary officers by one-fourth, and have forwarded to the Local Government Board a resolution declaring that the appointments of such officers were "mere sinecures."

The New Army Medical Warrant.

We have been favoured with an official notification from the War Office that the examination for the Army Medical Department, which was announced to be held in September, has been postponed, pending the consideration by the Treasury of the New Warrant.

It is hoped by the War Office authorities that the Treasury decision may be given in time for an examination to be held before the next session of the Army Medical School at Netley.

The Drug Nomenclature of the Unwashed.

Among some original specimens the *Chemist and Druggist* gives the following :—"Balocks and Hunney," "parragrack," "holoways," "extract hyoxyemus," "antyburlas pills," "Loddoni," "sotne withen" (stone whiting). Another chemist is asked to prescribe for a child "sick and no apletight," for another troubled with "a dredful roaring in his inside;" some one wants "a bottle of scent for diarrhœa in his head." Other requirements are "combination soda" (carbonate), "commode for the hair" (pomade), "bitter alice," "asissik assik" (acetic acid), "brucks" (borax), "fires of balsam," &c.

Vaccination by Unqualified Assistants.

The Huddersfield Board of Guardians have resolved that certain of their public vaccinators be called upon for a written explanation of irregularities committed by them in deputing their duties to assistants who were not qualified medical practitioners, and in signing on the vaccination registers their own names as having performed the operation, when the assistants had in fact vaccinated children. This action on the part of the Board was taken in consequence of a letter being received from the Local Government Board complaining of the practice.

Case of Hydrophobia.

At Ballyedmundduff, in the co. Dublin, a case of hydrophobia has occurred. About a month since, a little girl had been bitten by a rabid dog, and on Tuesday week she exhibited symptoms of the above disease. Last Friday the infant sufferer was in a state of great agony and died on Saturday. The father of the child and another man were afterwards bitten by the same animal, which was then destroyed by an old shepherd. Fortunately, the teeth did not enter beyond the surface.

Litholapoxy—Rapid Lithotrity.

This operation was recently performed by Mr. William Stokes in the Richmond Surgical Hospital, Dublin, and with complete success. The patient was an elderly man, who had been suffering acutely from stone in the bladder for the last two years. The calculus was removed in one sitting. This is, we believe, the first time Prof. Bigelow's operation has been performed in Ireland. We hope shortly to get full details of the case.

A boy, æt. 13, named John Thomas C. Jepson, son of a night watchman, died at the Leeds Infirmary, last week, from hydrophobia, caused by the bite of a dog.

Mortality amongst Homœopaths.

We give the following statement *quantum valeat* :—

There is a homœopathic life insurance office in New York which takes homœopathists at lower rates than others. Dr. Neville Wood, writing in the *Homœopathic Review*, gives the following as the "mortuary experience of 10 years" of this office, certified by the Government auditor :—7,927 policies to homœopaths, 84 deaths, 1·059 per cent.; 2,258 policies to non-homœopaths, 56 deaths, 2·92 per cent.

Fraudulent Drugs.

The *Pharmaceutical Journal* says, that at the drug sales in London there has been noticed this month some spurious matico, with an aromatic odour between that of aniseed and sassafras, and another kind with leaves extremely similar to those of matico, but quite inodorous.

A couple of weeks ago a shopkeeper at Armley was summoned for selling ¼ lb. of sweet spirits of nitre, which, according to the borough analyst's report, contained "scarcely any nitrous ether, on which the medicinal value of the liquid chiefly depended." The Town Clerk, who prosecuted, said, it was much to be regretted that persons who traded in these articles should not take the precaution to get a warranty from the wholesale dealers. The Corporation would proceed against the wholesale dealers if they could. The defendant said he sold the article in exactly the same state as he purchased it. The bench inflicted a penalty of 2s. 6d. and costs.

In the principal foreign cities the rates of mortality, according to the most recent weekly returns, were—In Calcutta 22, Bombay 39, Madras 36; Paris 24; Brussels 31; Amsterdam 17, Rotterdam 22; The Hague 22; Copenhagen 29; Stockholm 22; Christiania 17; St. Petersburgh 34; Berlin 29, Hamburg 25, Dresden 29, Breslau 35, Munich 30, Vienna 24, Buda-Pesth 38; Rome 26; Turin 25; Alexandria 42; New York 23; Brooklyn 23, Philadelphia 18, and Baltimore 19 per 1,000 of the population. Small-pox caused 6 deaths in Paris, and 11 in St. Petersburgh.

The individual who has been variously styled in the newspapers as Dr. Hammond, Mr. F. J. Hammond, F.R.C.S., but whose name does not, we are happy to say, appear either in the Medical Register, or the "Medical Directory," was brought up last week at the Central Criminal Court, under commitment for trial, on the charge of attempting to procure abortion in the person of Ellen Saunders, with whom he cohabited. The judge characterised it as a very serious offence, and he was sentenced to ten years' penal servitude.

The death-rate still continues very low throughout the United Kingdom—last week the mortality per 1,000 of the population in the principal large towns were—Portsmouth 11, Norwich 12, Edinburgh 14, Wolverhampton 15, Nottingham 16, Bradford 16, Plymouth 16, Birmingham 17, Glasgow 17, Bristol 17, Hull 17, Sheffield 18, Oldham 19, Leeds 20, London 20, Manchester 20, Sunder-

Digitized by Google

land 20, Leicester 21, Salford 23, Dublin 24, Newcastle-upon-Tyne 25, and the highest rate 26 in Liverpool.

Alstonia constricta is an Australian bark used in Queensland as a substitute for quinine, and is now coming into use in the United States. It is also known under the name of Queensland Fever Bark. It is quite different in appearance from Dita bark, which is used for dysentery rather than for fever.

THE subject selected for competition for the Fothergillian Gold Medal of the Medical Society of London in March, 1880, is "The Pathology and Treatment of Dysmenorrhœa;" for March, 1881, on "The Relative Value of the various Antiseptics in the application to Medicine and Surgery." Its value is 20 guineas.

THE resignation of Professor Attfield as Senior General Secretary of the Pharmaceutical Conference was announced at the termination of the Sheffield meeting, Professor Attfield has consented to hold office for one more year. A committee of members has been formed whose object is to raise funds for a testimonial in recognition of the devoted services which Professor Attfield has rendered to the Conference during its sixteen years of existence.

THE English Pharmaceutical Society has prosecuted a village grocer for selling laudanum not bearing a label with his name and address. The laudanum sold bore the name of "J. H. Elmitt, chemist, Horncastle," and also, it was said, bore a patent medicine stamp. But neither of these evasions availed, and defendant was fined £2 10s. and £2 12s. 6d. costs, an amount which he declared he was unable to raise.

DIARRHŒA, which has never shown a high death-rate this year, is still further declining; it was most prevalent in London, Liverpool, Salford, Leeds, and Leicester last week. Scarlet fever was somewhat excessive in Liverpool and Sunderland. Small-pox caused 5 deaths in Dublin, 1 in London, not another being reported from any other part of the United Kingdom.

BY Dr. Sedgwick Saunders' report it appears that during the fortnight ending the 20th ult., seven and a half tons of meat had been condemned in the City of London, as unfit for human consumption, and nearly three tons of putrid bacon, hams, and tongues, stated to have been sold to a soap-boiler, had been seized.

IN proof of the increasing popularity of the medical school attached to the London Hospital, we may mention that workmen have been engaged for some time on the enlargement of the dissecting-room, laboratories, library, &c., most of which is expected to be finished this week.

THE Government manufacture of quinine in India yielded last year a net profit of 42,412 rupees, or 4½ per cent. on the capital.

CHOLERA has again made its appearance amongst our troops in Afghanistan.

THERE were thirty-one deaths from yellow fever in Memphis last week—a smaller amount than for many weeks past.

UNIVERSITY COLLEGE HOSPITAL.

THE North London or University College Hospital is again opened, after being closed for important alterations, which have greatly increased its capacity and improved its organisation. The enlargement of space, for a considerable addition to the number of beds, has been gained by appropriating rooms on the top storey, heretofore chiefly used as sleeping apartments for the nurses. That no loss of necessary accommodation should follow this arrangement, certain houses in University Street have been brought into requisition, two of these tenements adjoining the main building; and besides the convenient lodgings which they afford for the Sisters of All Saints, Margaret Street, and their large and efficient staff of bedside attendants, additional chambers for special operations and treatment in connection with the wards for female patients have thus been gained. The changes have been effected at a total cost of not more than £3,500. There is no part of the establishment which has not shared the benefit of the moderate out-lay; new drainage works have banished the old brick-barrel drains, and a system of out-door pipes has been introduced. The walls, formed of a composition which has a marble smoothness of surface texture, called "Parian," have been coated with silicate paint. A simple dado character of decoration, with a warm, reddish chocolate for the lower ground, has been generally adopted. There is a separate ward for erysipelas in the highest floor of the north wing, and the sister and nurses attending the erysipelas ward are forbidden access to the other parts of the institution.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

HEALTH OF EDINBURGH.—For the week ending the 20th ult., the deaths in Edinburgh were 59 in number, and the death-rate was 14 per 1,000. The zymotic mortality was low; only one death from fever was reported, and that was a child in the Old Town. Of the 140 births, 9 were illegitimate.

HEALTH OF GLASGOW.—The death-rate of Glasgow for the week ending the 20th ult., was 17 per 1,000, as compared with 18 in the previous week. In the corresponding periods of 1878, 1877, and 1876, the rates stood at 19, 19, and 20 per 1,000 respectively. This shows an exceptionally good condition of the public health, and one now long-continued.

PAISLEY—THE PROPOSED NEW FEVER HOSPITAL.—The proposal to erect at Paisley a new fever hospital for Johnstone, Neilston, and the landward portion of the Abbey parish, is meeting with vigorous opposition from the townspeople of Paisley. On the 22nd ult. a requisition, intended for the Board of Supervision, against the proposal was numerously and influentially sigend. It is promoted by the five Paisley members of the Abbey Board's Sanitary Committee, who voted in the minority at a former meeting, against the scheme. A public meeting is talked of.

REGISTRAR-GENERAL'S RETURNS.—The weekly returns of births, deaths, and marriages, in the eight principal towns of Scotland, for the week ending Saturday, September 20th, says: "The death-rate in the eight principal towns during the week ending Saturday the 20th September, 1879, was 16·9 per 1,000 of estimated population. This rate is 2·2 under under that for the corresponding week of last year, and 0·1 above that for the previous week of the present year. The lowest mortality was recorded in Perth, viz., 11·7, and the highest in Leith, viz., 27·3. The mortality from the seven most familiar zymotic diseases was at the rate of 2·9 per 1,000, being the same as the rate for the previous week. Diarrhœa and diphtheria (under which croup is included) were the leading epidemics. Fifty-two deaths were caused by acute diseases of the chest, being 17 less than the number recorded during the previous week.

OUTBREAK OF FEVER IN KINNING PARK.—Several cases of fever have occurred within the past few days in Smith Street, Kinning Park, the affected persons being immediately removed to the joint hospital. A great many cases of typhus, typhoid, and scarlatina, are at present under treatment in several of the streets of the district of Plantation, and also in the joint hospital, from the same quarter.

ANDERSON'S MEDICAL SCHOOL.—AURAL SURGERY.—The managers of this school having resolved on appointing a lecturer on aural surgery, applications for the position are now invited. In the interests of professional propriety, we would beg to suggest to the managers that the successful candidate be prohibited from publicly reading the same paper on "Aural Surgery" more than six times, or at more than four different places; and that once published, such paper be regarded as sufficiently *aided* thereby, and not be re-read *ad nauseam*.

THREE CHILDREN POISONED AT AYR.—A singular occurrence, involving the death of three children, was brought to light at Ayr on the 25th ult. From information in possession of the police authorities, it appears that a little boy, aged three years, named Matthew McHarg, took ill about eight o'clock on the Sunday morning previous, and died at four o'clock on the following Tuesday. Another little boy, belonging to the same family, aged five years, took ill on Monday night, and also died on Tuesday morning about ten o'clock. A third boy, also a member of the family, aged seven years, took ill on Wednesday and died on the 25th ult., about noon. The three boys had all the same symptoms, being seized with violent vomiting and purging, and the medical man who attended them is of opinion that they had eaten something by which they had been poisoned. The father states that the boys had potatoes and herrings for their supper on Saturday night, just a few hours before the first boy, who died, was seized with the vomiting and purging. He also states that previous to Sunday they were all strong healthy children. The opinion of three local medical men is, that the symptoms exhibited were those of poisoning due to the use of unsound fish.

EDINBURGH NEW SCHOOL OF MEDICINE.—The new Minto House School adjoining both the Museum and the University, is now complete in all its departments. The teachers of the school have introduced a noteworthy feature—that is, the tutorial classes, in which a *resumé* of the preceding week or fortnight's work is given by the lecturers, and the more abstruse details explained. The certificates acquired at this institution are accepted by the University of Edinburgh.

Literary Notes and Gossip.

IN consequence of the illness of Prof. von Ziemssen, who has undertaken personally to write the volume on "Diseases of the Skin," vol. 9, of "Ziemssen's Cyclopædia," Messrs. Wood and Co., the publishers, have issued a notice to subscribers that it is probable that this volume will be delayed for some time to come.

* * *

AS there is no volume in "Ziemssen's Cyclopædia" devoted to Hygiene and Public Health, the publishers have thought that those who possess that valuable work would like to have added to it the "New Treatise on Hygiene and Public Health," edited by A. H. Buck, M.D.; they have had copies of it bound to match the various styles of the Cyclopædia.

* * *

IT would appear that dentists are not satisfied to receive their professional journals but once a month, consequently the publishers of the *British Journal of Dental Science* (Messrs. J. and A. Churchill), announce that in future it will appear fortnightly, which we presume is the commencement of a sliding scale towards a weekly issue. The publishers having done their part, the editor might, we think do his, by making the journal brighter and more attractive; it is entirely in his power to obliterate the chances of an opposition journal being started, which has been talked of lately.

* * *

As an outcome of the recent official inquiry on the prevalence of colour-blindness amongst sailors, signal men, and others, to whom an exact perception of colour is so absolutely necessary on account of the thousands of lives whose safety is placed in their keeping, Dr. Joy Jeffries, a well-known American author, has just published a work "On Colour Blindness, its Dangers and its Detection." In this work a good deal of research is evident, and though the author has produced nothing new or startling, he has nevertheless collated much valuable matter, and has succeeded in getting a good many facts and figures from members of the profession in this country. The novelty in binding is likely to remain so, very few, we opine, will be induced to copy our author's wrapper in three colours, scarlet, green, and violet; as a rough and ready test for colour-blindness, it disarms criticism.

* * *

A VERY useful little pamphlet has just been issued by Messrs. Ingram and Royle, under the title of "Natural Mineral Waters, their Properties and Uses." Owing to the wonderful success of the Apollinaris, Vichy, Friedrichshall, and one or two other waters, quite a multitude have been introduced from time to time, each claiming to be the best, purest, most efficacious, and most necessary, until the practitioner has become almost bewildered which to prescribe. This little pamphlet gives an analysis of all the known waters (about one hundred), their history, doses, and uses, arranged in alphabetical order, so that the reader has but to turn to the water about which he has any doubt, to obtain the required information. We may add that gratuitous copies will be sent to qualified practitioners, on applying by letter to Messrs. Ingram and Royle, 119 Queen Victoria Street, London, E.C.

* * *

ONE of the most popularly known medical authors has just passed away in the person of Mr. Pye Chavasse, F.R.C.S., of Birmingham, from cerebro-spinal sclerosis. We say *popularly known*, because his works were written for the general public, and were probably more widely read by them than any other medical works in the English language. And although the profession is apt to look upon popular medicine books with a considerable amount of suspicion; this much could be said of Chavasse's efforts, that they were such as popular works should be, aids to the profession, in teaching young mothers how best to take care of themselves and their offspring; not "how best to do without a doctor." Some of these books have gone through several editions: "Advice to a Mother" is in its thirteenth, "Advice to a Wife," twelfth, "Counsel to a Mother," third," and "Aphorisms," the second edition.

* * *

MESSRS. COLE & SONS, the well-known manufacturers of pathological specimens for the microscope, have prepared a new series of organic aromatic bodies derived from the coal tar, crystallised for the micro-polariscope and paroboloid. They may be taken as a good exercise for philologists and phonologists. The following is the list:—Metanitraniline, paranitraniline, sulphanilic acid, calcic sulphanilate, diphenylamine, diphenylnitrosamine, mononitrodiphenylnitrosamine, orthodinitrodiphenylamine, paradinitrodiphenylamine, dibromodinitrodiphenylamine, dimethylamidoazobenzene, diphenylthiourea, tropæoline, picramic acid, dinitrobenzene, diacetylphenylenediamine, paranitrotoluol, phtalic acid, phtalimide, naphtalenetetrachloride, diimidonaphtol, tropæoline, anthracene, anthraquinone.

* * *

THE new English Dictionary of the Philological Society, projected twenty years ago, is now at length, under the auspices of the Oxford University Press, about to be completed; and an appeal has been put forth by the Dictionary Committee of the Society for volunteer assistance in reading and extracting the numerous books not yet examined for the purpose. Between 300 and 400 volunteers are at present "reading" for the dictionary; up to the end of August they had completed 221 books representing some 300 volumes, which had yielded 81,600 quotation slips; while 485 books were in process, representing twice as many more quotations. Much interest in the matter has been awakened in the United States, where the articles on the subject in the English literary and other journals have been quoted and commended to attention by the newspapers in all parts of the country.

Obituary.

JAMES CHARLESWORTH COPLAND.

THE profession has suffered a severe loss in the death of this able man. He was educated at Middlesex Hospital, and after taking his diploma he served in the Osmanli Irregular Cavalry during the Crimean War. He soon afterwards entered into general practice, but he was never calculated to succeed as such; and it was not to be wondered at that he withdrew almost altogether from practice, and devoted his time to literary work. He was almost solely the author of the abridged edition of "Copland's Medical Dictionary," and of very many able leaders which have appeared in the *Medical Press and Circular*. For many years he has been a member of the Court of Examiners of the Apothecaries' Hall. Mr. Copland was a great classical scholar, and throughout life has been a great reader. His companionship was eagerly sought, for his large general knowledge made his conversation instructive. His writings were those of a deep thinker—elegant, clear, and powerful. His knowledge of medicine was extensive, and he had great discrimination in the diagnosis of disease; and there is no doubt that had he in early life been able to wait his time for consulting practice, he would have taken a very high position in the profession. His courteous manners had endeared him to a large circle of friends, and his early death will be universally regretted, and by none more than ourselves for the loss of a most able colleague and amiable friend. Five days before he died he was taken with the most painful cramps in the bowels, accompanied by obstruction, tympanitis, and stercoraceous coffee ground vomiting, and other signs of valvulus, the probable cause of death.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

DR. C. R.—Paragraph to hand: see our Current Topics.

DR. FOOTE, Dublin.—We believe that Youatt wrote a special treatise on canine madness.

ARMY MEDICAL SERVICE.—Our attention has been directed to the letter. You know the old saying that "As the pipers play so the people dance," and in this case subordinates dance to the tune set by the War Office.

DR. L.—The best guides you can have are the following: Wood and Bache—"United States Dispensatory;" Egleston—"Table of Weights and Measures;" Eggleswaith—"The Metric System explained in a Nut-shell;" Browne—"The Metric System for Physicians;" Mann—"Manual of Prescription Writing;" Seguin—"Prescription and Clinic Record," xxiii. xxiv. ed. We have no doubt they can be obtained of the foreign publishing houses in London.

MARTIN'S BANDAGES.—The original bandages were, and are still, made by Krohne and Sesemann. Other firms now manufacture them.

ZULULAND—The Cape was a good field for the emigrant doctor. The Zulus will require doctors when they are civilised. You might aid in the work. They have not the character of liking "cold missionaries."

MR. C. L. HENDERSON, Kokomo, Indiana.—Our last number will give you every information with respect to the various universities and medical schools in the United Kingdom; the present issue, that for other European universities. It is contrary to our custom to recommend any particular school.

DR. GRIFFITH.—Your paper is not forgotten; it will appear in rotation with others received before it.

THE IRISH COLLEGE OF PHYSICIANS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Kindly inform a reader if the Privy Council have approved of the new bye-laws of the King and Queen's College of Physicians, and if a licentiate can now be admitted to the membership, and oblige

Yours, &c.,

Sept. 18, 1879. 1879.

[On inquiry we are informed that no confirmation of the new bye-laws has reached the College officially, and, therefore, the provisions are not yet in force.—Ed.]

OBSTETRICAL SOCIETY OF LONDON.—This evening (Wednesday), at 8 o'clock, Cases: "Cholera in the New-born," by Dr. Lucas. Papers: "Deficient Development of the Uterus, Atresion of the Os Externum, Atrophy of the Ovaries," by Mr. Alban Doran; "Case of Congenital Inguino-Ovarian Hernia (double); Operation," by Dr. Chambers; Report of Sub-committee on the specimens removed.

DR. SEGUIN, New York.—Letter and papers received, and shall have our best attention.

SURGEON-MAJOR W. CURRAN.—We shall be happy to accept your papers for publication if you can summarise the results now contained in tabular form (too large for our pages) in paragraphs. As it at present stands it would be impossible to give the necessary space.

DR. THOROWGOOD.—Letter will appear in our next.

O. J. CARAHER.—Letter received when we were at press.

VACANCIES.

Brompton Consumption Hospital.—Resident Medical Officer. Salary, £200, with board. Applications to the Secretary before Oct. 8.

Fareham Union, Hants.—Medical Officer for the Titchfield District. Salary, £100, with usual extra fees. Immediate applications to the Clerk of the Board.

Leicester Infirmary.—Physician on the Staff. Honorary. Applications to the Secretary before Oct. 6.

North Shields Dispensary.—House Surgeon. Salary, £120. Immediate application to the Hon. Sec.

Oakham Union.—Medical Officer for Workhouse and District. Salary, £80, with usual extra fees. Applications to the Clerk before Oct. 14.

West End Hospital for Paralysis.—Assistant Physician. Honorary. Applications to the Hon. Sec., 93 Welbeck Street, London, W.

APPOINTMENTS.

ADAMS, J. E., F.R.C.S.E., a Surgeon to the London Hospital.

BENTHALL, W., M.R.C.S.E., a Resident Clinical Assistant to the East London Hospital for Children.

CARLISLE, J., L.F.P.S.G. & L.M., Certifying Factory Surgeon for the District of Crossgar, co Down.

CHAPLIN, S., F.R.C.S.I., Medical Officer (*pro tem*) to the Kildare Dispensary, Naas Union.

COATES, E., L.F.P.S. Glasg., Medical Officer to the Portumna Dispensary, Portumna Union.

COYNE, F. K., L.R.C.S.I., Medical Officer (*pro tem*) to the Ballyroan Dispensary, Abbeyleix Union.

DENNING, F., L.R.C.S.I., Apothecary to the Sligo Dispensary.

FULLER, L. H., M.R.C.S.E., House Surgeon and Secretary to the Royal Hants County Hospital, Winchester.

HUGHES, W. L., M.R.C.S.E., Medical Officer for the No. 1 District and the Workhouse of the Carmarthen Union.

LENTAIGNE, J. V., L.R.C.S.I., Resident Surgeon to the Richmond Hospital, Dublin.

MILLER, Surgeon-Major O. B., Deputy Lieutenant for co. Mayo.

ROGERS, T. W., L.R.C.S.I., Medical Officer for the Hacketstown and Coolkenna Dispensary District, Shillelagh Union.

TREVES, F., F.R.C.S.E., an Assistant Surgeon to the London Hospital.

Births.

BARRY.—On September 22, at 3 Glentworth Street, Limerick, the wife of Robert Barry, L.R.C.S.I., of a daughter.

DAVIS.—On September 21, at Newbridge, co. Kildare, the wife of Surgeon-Major J. Norman Davis, Army Medical Department, of a daughter.

NELIGAN.—On September 22, at Tralee, co. Kerry, the wife of J. W. Neligan, M.B., of a son.

Marriages.

ATKINSON—BERRIDGE.—On September 25, at Sibbertoft Parish Church, Joseph Atkinson, L.R.C.S.I., L.K.Q.C.P., of Eggleston, to Elizabeth, youngest daughter of William Berridge, of Sibbertoft.

BRUNTON—STOPFORD.—On September 29, at St. Peter's Church, Dublin, Thomas Lauder Brunton, M.D., F.R.S., of London, to Louisa Jane, youngest daughter of the late Venerable Edward Alderley Stopford, LL.D., Archdeacon of Meath.

Deaths.

BENNETT.—On September 3, at Leatherhead, William Bennett, M.R.C.S.E., aged 69.

CHAVASSE.—On September 20, at Hagley Mont, Hagley Road, Pye Henry Chavasse, F.R.C.S., in his 70th year.

COPLAND.—On September 18, at Coniston Lodge, Ealing (suddenly), J. Charlesworth Copland, M.R.C.S., some years sub-editor (English Department) *Medical Press and Circular*. Editor of "Copland's Dictionary of Medicine." Aged 48. Sincerely regretted by his colleagues and friends.

GAYE.—On September 8, at Newton Abbott, Charles Gaye, M.R.S.E., aged 84.

HENDERSON.—On September 9, at Ferryhill, Alexander Henderson, Surgeon.

KELLY.—On September 3, in the massacre at Cabul, Ambrose Hamilton Kelly, L.K.Q.C.P.I., Medical Officer to the British Embassy.

LAUGHLIN.—On September 17, at Gortin, Alexander Laughlin, M.R.C.S.Eng., late Surgeon R.N., aged 88 years.

MONTGOMERIE.—On September 26, at Edinburgh, Mary Campbell, widow of James Montgomerie, M.D.

OGILVIE.—On September 21, at Walmer, John Forbes Ogilvie, M.D., of Norwood.

RITTERBRANDT.—On September 26, at Kensington, Louis Antoinette Ritterbrandt, M.D., aged 71.

SIDNEY.—On September 23, at 19 Herbert Street, Dublin, Frederick John Sidney, LL.D., Secretary to the Royal College of Science for Ireland.

WICKHAM.—On September 20, at Holloway Road, London, N., Edward Wickham, M.R.C.S.E., aged 84.

IRISH POOR-LAW INTELLIGENCE.

REMUNERATION OF MEDICAL OFFICERS OF HEALTH.

THE following letter has been sent by the Irish Medical Association to the Local Government Board :—

Irish Medical Association,
Royal College of Surgeons, Dublin,
Sept. 17th, 1879.

TO THE SECRETARY, LOCAL GOVERNMENT BOARD.

SIR,—The Council of the Irish Medical Association having learned that the Local Government Board have issued a circular calling attention upon the Local Sanitary Authorities to furnish a return showing the amount of salary paid to each dispensary medical officer for his services as medical sanitary officer under the repealed "Public Health (Ireland) Act, 1874," and also the amount of salary proposed to be given to each medical officer of health under the new Public Health Act, I am directed by the Council to express their decided opinion that unless the medical officers of health are awarded salaries commensurate with the duties imposed, it cannot be expected that those duties will be fully and efficiently discharged.

The Council are aware that for some little time after the passing of the Public Health Act of 1874 considerable zeal was manifested by many of the medical sanitary officers (as proved by the Parliamentary return made to the House of Commons upon the motion of Dr. O'Leary, M.P.), and there can be no doubt that that energy was exercised in expectation that their services would soon be appreciated, and that the salaries appointed—which, as a rule, were utterly disproportionate to the nature and extent of the duties—would thereupon be increased.

However, the medical officers soon found that the scale fixed, as directed by that Act, precluded the possibility of equitable remuneration being allowed for efficient services, and that their interests as medical practitioners were very seriously and prejudicially affected by the faithful discharge of their duties, and in consequence of the evident discouragement shown by the Sanitary Authorities to anything like efficient service, the result was a marked falling off in the efforts of the medical officers which, eventually greatly diminished.

Ever since the new Public Health Act was passed the newly-appointed medical officers of health have been waiting to see how their services would be valued before entering upon the duties with that ardour which is so essential to the well-being of the public; but in consequence of the small amount of work recently performed by the medical officers, the Council fear that the Local Sanitary Authorities may avail themselves of this as a pretext for either not proposing an increase in the amount of the former salary, or even possibly of suggesting that it should be diminished, though it is inconceivable that they could fall into the error of supposing that the amount of work which due regard for the public health requires to be done is insignificant.

The Council confidently expect that the Local Government Board will not confirm the allotment of any salary to a medical officer of health which is not equitable remuneration for efficient service; and if this expectation be realised, there will be no excuse for omission to discharge the duties imposed.

The Council observe that by the new Act, and also by the recently-issued sanitary orders, additional duties have been assigned to the medical officers, which it is expected will not be overlooked as entitling them to still further remuneration.

I am directed to remark that unless, and until, reasonable and equitable remuneration is allowed to the medical officers of health, it is futile to imagine that the provisions of the Public Health Act can come into effectual operation; and further that the past work done by those officers cannot be considered to indicate the amount of remuneration that should now be allowed, but that, on the contrary, the amount of the salary will to a great extent regulate not only the manner in which the duties will be performed, but also the extent of them which will be voluntarily undertaken; and in the absence of any provision for supervision, this appears to be a very important consideration.

As the delay in fixing the salaries to be paid under the new Act did not result from any fault or omission on the part of the medical officers of health, or of the Irish Medical Association, as the representative body of the profession in Ireland, the Council expect that the new salaries will be paid from the date of the commencement of the new Act.

The Council, also, as a body ever mindful of the public interests, trust that an assurance will be given to the medical officers of health that the amount of their salaries will be subject to reconsideration from time to time; zealous and efficient services, as well as the extent of them, being duly recognised, as the justice of such an arrangement is beyond question.

The repealed Act was authoritatively alleged to be "merely a *tentative* measure;" but as the new Act is an *amending* one, it cannot be so considered. It is therefore to be assumed that its provisions are meant to be carried out thoroughly, and that none of them are intended to be inoperative; but it cannot be supposed that Parliament, in compelling the dispensary medical officers, without option of refusal, to be the medical officers of health, meant or intended that their services should not be fully and adequately remunerated; indeed, the justice of the claims of the medical officers to more liberal remuneration than hitherto allowed, was admitted not only by the Government, but also by Parliament, as evidenced by the withdrawal of the fixed scale.

To the Local Government Board, therefore, the Council earnestly commend the consideration of this very import-

Digitized by Google

ant subject in all its bearings, it being but reasonable to expect that the work done will only be proportionate to the salaries paid; and as the success of the measure depends chiefly upon the exertions of the medical officers of health, the responsibility of another failure in this direction will therefore, to a great extent, rest upon the action in this matter which the Local Government Board may decide upon adopting—the question of the amount of success to be obtained resolving itself into one of proportion between work and payment.

The Council, though most anxious to facilitate and insure the completely successful operation of the provisions of the new Act, nevertheless cannot approve of supporting any arrangement which, whilst compelling the medical officers of health to hold office and discharge onerous and important public duties, would not afford them adequate remuneration; and in this view they feel confident they will meet with the hearty support of Parliament, the public, and the medical profession.

I am, Sir, your obedient servant,

JOHN WILLIAM MOORE, M.D.,
Hon. Sec. to the Council.

40 Fitzwilliam Square West,
Dublin.

REDUCTION OF SANITARY SALARIES.

THE following letter has been addressed to the Local Government Board by the Medical Officers of the Carrickmacross Union:—

TO THE LOCAL GOVERNMENT BOARD FOR IRELAND.

GENTLEMEN,—We, the dispensary medical officers of the Carrickmacross Union, are again reluctantly compelled to draw your attention to the action of the Carrickmacross Board of Guardians on the 23rd inst. in adhering to their resolution of the 9th inst., reducing our salaries under the Public Health Act from £15 to £10 a year, notwithstanding the fact that the Local Government Board, in refusing to sanction the reduction, pointed out that our duties were increased by the Act of 1878.

In the resolution passed at the board on the 23rd inst., we have failed to discover a single well-founded argument in favour of the proposed reduction, but it contains statements which are not strictly in accordance with facts. It states that our salaries were increased £20 a year each on the plea that the expense of living had increased.

Our salaries were not increased on any such plea, and in two of the districts, namely, Carrickmacross and Donamogue, the salaries were not (properly speaking), increased at all. It is true that Dr. Clarke's salary was increased several years ago from £80 to £100 a year. The late Dr. Duffy, as medical officer of Donamogue, had £100 a year, and after his death the salary was reduced to £80, at which Dr. Garland was appointed; but soon after his appointment the salary was restored to the sum paid to Dr. Duffy, namely, £100. Dr. Tagert, as medical officer of Carrickmacross district, had £120 a year, and when he resigned, the salary was reduced to £100, at which Dr. McKenna was appointed. Dr. McKenna's salary was soon afterwards restored to £120, the amount paid to Dr. Tagert. It will be seen from these facts that our salaries were not increased on the plea of increased expense of living as stated in the resolution of the guardians.

As to the cost of living being less now than formerly, as insinuated in the resolution of the board, we assert without fear of contradiction, that every necessary of life is quite as dear now as ever.

The reasons given in the resolution for reducing the salaries are, the depressed state of the times, and the fact that by the new Vaccination Act our fees are doubled. We consider that such reasons require no comment from us. There is one paragraph in the resolution of which we confess we cannot see the meaning. It commences, "Some medical officers seem to ignore, &c."

We are not aware that we have ignored the board of guardians, unless our protest to the Local Government Board against the unjust reduction proposed be considered as ignoring them.

As to the tone of our letter, we do not think the remarks made in the resolution are at all called for, as there was nothing whatever disrespectful to the guardians, or to any one else.

The guardians state they are of opinion that £10 a year is sufficient remuneration for our duties under the Public Health Act. If the medical officers of health carry out the provisions of the Act (and we are, and always have been, willing and anxious to do so), £10 as salary is simply ridiculous.

Under all the circumstances we trust the Local Government Board will now see the necessity of complying with our letter of the 10th inst., and that they will themselves fix our salaries at a reasonable amount.

We are, gentlemen,
Your obedient servants,

ARNOLD BLAKE, M.D.,
CHARLES GARLAND, L.K.Q.C.P.I., &c.,
WM. KENNA, L.R.C.S.I., &c.

Carrickmacross, Sept. 24, 1879.

The resolution referred to was proposed by Thomas Phelan, and seconded by Thomas McCabe, and is as follows:—

"The Guardians wish to state that considering the duties performed by the sanitary officers under the Public Health Act, coupled with the depressed state of the times, they were, and are still, of opinion that the sums proposed are sufficient remuneration for the duties they have to perform. Many of the guardians have been of opinion that a revision of the salaries of many of the officials should be made with a view of reducing them, but owing to the disinclination of the Local Government Board to consent to a reduction under almost any circumstances, they hesitated to move in the matter, but now that new salaries have come to be fixed they think this a proper opportunity to deal with it. Having regard to the fact that the salaries of the medical officers were increased £20 each on the plea that the expense of living had considerably increased; now as this plea can be no longer maintained, and as the remuneration of those officers under the Vaccination Act has been doubled, we think they have very little reason to complain. Then again, that the performance of their duties under the Public Health Act is calculated to injure their private practice. In this we cannot agree with them, as we find from our experience that the class of persons reported to us as not complying with the sanitary laws are of the class that are not likely to consult a doctor except under the Medical Charities Act. Some medical officers seem inclined to ignore the existence of the guardians, and relying on the sympathy of the Local Government Board, seem determined to have things pretty much as they like, as is evidenced by the tone of the three medical officers in this case. We do not think that encouragement of a line of conduct which is calculated to lower in public estimation the status of representative bodies is likely to tend to the public good. It was not expected that a word would be said in favour of maintaining the office of consulting sanitary officer as it had become a perfect sinecure. There were only three or four consultations during the whole time the office existed, and the information required could have been obtained from the sanitary officer of the district; yet those officers would try to perpetrate what is not only an anomaly, but a glaring waste of public money. However, should the duties of the officers of health be found to be considerable, the guardians will not hesitate to take the matter again into consideration with the view of increasing the remuneration as they did on former occasions when they increased the salaries for dispensary duties."

CORRESPONDENCE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In these hard times there are none who feel more the general depression than the dispensary medical officers. My number of visiting increased within the last six months to an alarming extent. A man, the proprietor of two farms of sixty acres each, presented me with a scarlet runner some days ago to visit his son, in fever. Feeling a bit nettled at this treatment, I asked him how long since he qualified for a "pauper's ticket." I have been called to order by my committee, and informed that if the like occurred again, I would be reported to the Local Government Board.

Now, Sir, I ask you what would be the consequence if I were reported to the Local Government Board? What written or unwritten laws have I transgressed?

Faithfully yours,
A DISPENSARY HACK.

19th September, 1879.

[Our correspondent's inquiry of the farmer was quite reasonable under the circumstances, but there is not much to be gained by showing one's teeth without the power to bite. The Local Government Board would probably disapprove of any expression of annoyance, but could not do more than reprimand. Our correspondent ought to have remonstrated on paper, and applied to the Committee to cancel the ticket, appealing to the Local Government Board for redress if they refused to do so. This would have annoyed the farmer much more, and protected our correspondent more effectually.—ED. M. P. & C.]

MEDICAL ATTENDANCE ON ROYAL IRISH CONSTABULARY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I think that it is unfair to the "medical attendants" on the Royal Irish Constabulary, that the allowance for attendance on the married men is not paid for whatsoever portion or entire of a month, by which they are absent from their barrack on duty, or otherwise, although their wives and children still remain under the charge of the "medical attendant," and it is unnecessary for me to state that the families require much more attendance than the men. For instance, a married man is ordered on duty from Delvin Barrack to the north of Ireland, he leaves his wife and children behind him at Delvin; during his absence the "medical attendant" at Delvin does not receive any payment for whatever attendance, &c., which may be required and given to his family. It is a question for consideration whether medical attendance ought to be given in such cases, when the allowance is stopped. Hoping that I shall not be trespassing on the space of your valuable journal by asking you to insert this, in the hope that the grievance may be remedied.

I am, &c.,
WILLIAM CARLETON, M.D. T.C.D., &c.

Delvin, 22nd September, 1879.

LIMERICK SANITARY BOARD.

SALE OF FOOD AND DRUGS AMENDMENT ACT.

Read, the following letter:—

"16th September.

"SIR,—The Local Government Board for Ireland forward to you herewith for the information of the sanitary authority a copy of the Act last sessions for the amendment of the Sale of Food and Drugs Act, 1875. The provisions of the Act, 1875, which prescribe the mode of providing to obtain analysis and a certificate of the result of such analysis, upon which, if an offence had been committed against any of the provisions of the Act, proceedings might be taken when communicated to the sanitary authority in the Board's circular letter of the 3rd November, 1875.

"By order of the Board,
"B. BANKS, Sec."

Marked "read."

A letter was read from the Sec. of the Local Government Board stating that he had been directed to acknowledge receipt of minutes of proceedings of the Limerick Urban Sanitary Authority at their meeting of the 9th inst., and with reference to the minute postponing the erection of a disinfecting chamber, I am to state that there can be no doubt of the advantage which would be derived from the use of such a structure, and without it the Sanitary Authority can hardly discharge their duty under sec. 137 and 139 of the Public Health Act. The use of such a chamber is one of the means within the power of the sanitary authority for ameliorating the unhealthy condition of the city, and it should no longer be neglected. The expense is moderate, and full particulars can be had at the union workhouse, where one has been erected. The board requested that the sanitary authority would have the goodness to take the matter again into consideration.

Ald. Myles suggested to have the letter marked read, which was accordingly done, and the matter dropped.

SALARIES OF MEDICAL AUTHORITIES.

Mr. Corbett read a letter from the Local Government Board regarding the increase of the salaries of the medical officers. He said that it was proposed by Mr. Hosford on the 11th March last that the salaries of the medical officers be increased from £15 to £25 under the conditions that the doctors would supply all the required statistics, and any extra duties that the board would put upon them under the Sanitary Act.

Ald. Myles asked to have a copy of the resolution sent to the Local Government Board, and see what they had to say to the matter.

Mr. Corbett said the Treasury approved of the increase that the medical officers under the Sanitary Board asked.

Ald. Myles—But was a copy of the resolution forwarded to the Local Government Board?

Mr. Corbett said that he was not ordered.

After some further discussion it was decided that the resolution passed by Mr. Hosford, which was approved of by the Board, be rescinded. The Board now decline to grant any further increase of the salaries of the medical officers.

ABSTRACT OF REPORT ON THE DISTRICT, CRIMINAL, AND PRIVATE LUNATIC ASYLUMS IN IRELAND

(Continued.)

Under existing circumstances it is clear, as suggested by the resident physician, that additional provision against growing pressure may soon be urgently needed at the Dundrum asylum, as nothing could be more detrimental to such an institution than a deficiency of means for classification and a due supervision. There appear to us only two alternatives to meet exigencies, and at the same time obviate an enlargement of the buildings, one having regard to the ages of the inmates, there being in it patients old, decrepit, harmless, and inoffensive, some of whom, if not guilty of homicide or crimes of a grave character, might be pardoned, discharged, and disposed of locally—government paying for their maintenance elsewhere, and thereby saving fully £16 a year per head during their lives; the other, by adopting a suggestion at one time mooted by us, which has found favour in various American States, particularly in Pennsylvania, where, as Dr. Kirkbride says, "Settle the matter as we may, part of a prison must be converted into an hospital for insane, or part of an hospital into a prison; it needs no argument to show that the first is more desirable, injuring no one, and scarcely depriving any one of a single important advan-

Digitized by Google

tage." If then at any existing or future depôt, in a wholesome locality, with ample ground around it, a small portion of the premises could be allocated to convict prisoners attacked, while under confinement, with actual or pretended mania, the expense of structural additions at Durham, where the amount of land is restricted, would be avoided.

We ourselves have long felt that "the stimulation of madness exercises a baneful influence on prisoners, inducing them to attempt a similar course in the hope of removal to an asylum, where restraint being less, the chances of escape become greater.

Of the present inmates in the Central asylum—numbering 140 males and 37 females—69 are entered as homicides—57 males and 12 females; while of persons charged with assaults endangering life, and with others of an aggravated character, there are no less than 41; 4 only being of the female sex. There are 11 individuals convicted of burglary in the house—all males; the difference, making up a total of 177, is composed of minor offenders under confinement, in equal proportion as to sex. There were seven discharges in the year just expired—the period of imprisonment having terminated in each case; they were relegated to their native district asylums; 6 died from natural causes. No accident nor attempt to escape occurred.

As regards education, 54 per cent. of the inmates are utterly uninstructed, while 70 per cent of those in ordinary asylums can read or write. The unmarried stand fully as 3 to 1 in proportion to the married and widowed. Somewhat more than half of the males belong to the farming and labouring classes; 11 were soldiers or members of the police force. The remainder had been engaged in various trades, or were employed in domestic occupations.

Classified as to their mental condition, 10 are only recognised as being of sound mind; 18 are probably cureable, who, in the event of recovery, will be duly brought by us under the notice of the executive; 149 labour under various types of insanity. As a rule, we are happy to report that the inmates of the Dundrum asylum are well disposed and orderly—very many of them industriously employed; for example, 72 men on an average are daily occupied on the farm, within doors, in ordinary domestic, or artisan works; and 24 women in the laundry or in assisting the attendants.

Religious observauces are not neglected—there being two very neat and separate chapels (Protestant and Catholic) where clergymen regularly perform divine service.

The fullest liberty compatible with the safety of the patients, and that freedom from an undue restraint observable in well-regulated asylums, continue to characterise the management of this institution.

The capitation rate, a few shillings less than in the preceding year, amounted to £35 in 1878, as calculated on expenditure and the daily average under treatment

Subjoined is the report of Dr. Ashe, Resident Physician:—

"Central Asylum, Dundrum,
13*th May*, 1879.

"Gentlemen,—I have the honour herewith to submit to you my report on the asylum for the ysar ended 31st December, 1878, to accompany the statistical tables for the same period.

"I am happy to be able to give a favourable report regarding the health of the inmates during the year. The deaths have been only four males and two females, making a total percentage of less than 3·5 on the daily average number of patients—viz., 172. One of the male patients died from typhoid fever, with severe pulmonary complications: the other deaths were due to the usual chronic and senile diseases commonly to be found among asylum patients. No death occurred through violence or suicide, and no serious accident took place within the period referred to, neither did any escape occur. The admissions were 23, and the discharges 7, leaving the number of inmates increased by 10, as the result of the change of population during the year. The pressure on our space, already too limited, has thus become much more inconvenient, alike in dormitories, dayrooms, and dining-hall.

"The expenditure for the calendar year 1878, under the Treasury sub-heads, amounted to £,300 2s. 2d., and that on the farm and garden to £423 9s. 4d., making a total outlay of £6,723 11s. 6d. Against this must be set off on the credit side the proceeds of the farm and garden being valued at £699 8i. 2d., which, with Exchequer extra receipts, £2 16s. 6d., and the small sum of 17s. 6d. fines, makes a credit tota of £703 2s. 2d., leaving an annual cost of æ6,20 9s. 4d., or exactly £35 per head on the average number of patients resident. The farm produce, it must be again observed, is, according to Treasury instructiocs, estimated at the lowest possible figure, so as in each financial year only just to cover the actual expenditure under this sub-head. If valued according to market prices it would considerably exceed the sum named. The moral condittion of the inmates has been satisfactory during past twelvemonth'; seclusion has rarely been necessary, and mechanical restraint has only been used in two cases. One of these was a demented male patient, who was in the habit of suddenly and without any provocation knocking down on the flags any aged or feeble patient who might happen to be near him. His intelligence not being capable of apprehending either remonstrance or confinement, I determined to try and break this dangerous habit; and accordingly I confined his hands merely by a belt and straps. This treatment, persevered in for three months, was, as I had hoped, completely successful in curing him of his dangerous propensity. The other case was a female, liable to sudden and violent outbursts of homicidal mania. Deeming it essential to adopt some means of protecting patients and attendants alike against her violence, and finding prolonged seclusion injurious to her health, I allow her to go about with a loose but strong canvas camosile over her dress, her hands being free inside; she thus enjoys a good deal of liberty without danger to others.

"The contract provisions and clothing supplied during the year have been in most cases satisfactory. I have, however, been occasionally dissatisfied with the bread supplied, as being inferior to the sample furnished. Samples of such provisions unfortunately cannot be kept for comparison.

"I have to advert to the difficulties arising in the management of the house, and indeed the danger incurred by patients and attendants alike, as also the chances of escape of the patients in consequence of the fact that at present no authority empowers me to engage temporary attendants on the staff while a vacancy is being permanently filled. It has more than once happened in consequence that, the staff being, from various causes, reduced in numbers, there has been, at particular times of the day, but one attendant who could be placed on duty to watch an entire division. I trust this matter may receive your earnest consideration; and that I may receive authority to engage at any moment a temporary *employé* to fill for the time being a casual vacancy on the staff.

"I am, gentlemen,
"Your obedient servant,
"Isaac Ashe, M.D. T.C.D.

"The Inspectors, Asylums Office."

(*To be continued.*)

TO READERS.

The Editor will feel especially obliged by receiving copies of newspapers which contain any Poor-law or other intelligence of medical interest, in order that he may, if fit, republish it for the benefit of the readers of the *Medica Press*. Although twenty-one of the leading Irish newspapers are received at the Irish office, many things may escape notice which are deserving of attention. Newspapers should be marked, and addressed to Dr. Jacob, at the Dublin offices of this paper.

THE ADVANTAGES OF CALOMEL IN THE DISEASES OF CHILDHOOD, WITH ESPECIAL REFERENCE TO TYPHOID FEVER.

By E. MARLETT BODDY, F.R.C.S., F.S.S., etc.

(*Continued from page* 285.)

It would be useless to call the reader's attention to the numerous names which are given to the supposed different forms of diarrhœa, whether in infancy, or amongst adults, because they are, no doubt, too well-known to require enumerating; and neither will I mention the various drugs which are in vogue, for their name is legion, besides they are all given with one intent, viz., to obviate the attack, whether it springs from one cause or another. Such a proceeding as this, to my mind, is not conducive to the advance of medical science; because, if there are so many different forms of diarrhœa, each particular phase of it must, of necessity, require a different mode of treatment; but if we reduce all to one main spring or origin, then one method of treatment is all that we may pursue, and which we shall find, to a certainty, will meet all our requirements, especially if we view the matter totally apart from mystifying technicalities and intricate theories.

The multiplicity of names, when one would suffice for all rational purposes, naturally perplexes and leads many at once to presume that diarrhœa, instead of being a simple effort of nature, is an occurrence highly dangerous and indicative of mischief of some kind or other; and which must therefore be met, not as a friend to health, but as an enemy full of sinister designs and dark intentions.

I cannot but help thinking that we are more apt to do harm than good by having so many divisions and subdivisions of one condition. Abnormal states of the human system cannot possibly be rectified if we resort to, and depend upon terms which are not only questionable as regards the correctness of their definitions, but are very likely to cause the unthinking to diverge altogether from the object which it is desirable to attain.

The proceeding sufficiently demonstrates, I think, the various reasons why diarrhœa is regarded as such a dangerous condition, and also fully accounts for the erroneous treatment which is decidedly inimical to a thorough restoration of the functions of the intestinal tract, and which is so strongly advocated by the great majority of the medical profession.

The remarks I have made regarding the administration of calomel in convulsions, teething and diarrhœa, are equally applicable in other diseases which are incidental to infancy, whether they be cerebral, thoracic, abdominal, or zymotic; because in all these abnormal conditions the bowels are to a certainty either confined or relaxed, or as some would term it diarrhœic, and the colour and odour of the alvine excreta are totally different to what they present in health, to the peculiarities of which I have already adverted.

However, there is one great fact which shows the vast importance of attending to, and regulating the action of, the intestines, for they are always in an abnormal condition, whether the child is suffering from hydrocephalus, bronchitis, tabes mesenterica, or scarlet fever, and as a consequence, the administration of purgatives must not be omitted if we wish the child to recover thoroughly and speedily, for though the viscititudes of the attack may be frequent, so as to render it necessary to vary the treatment, yet as concerns the alvine excreta, there will be no variation nor change during the disease; therefore it is really important and imperative that more than ordinary attention should be paid to the intestinal canal.

I have asserted at the commencement of my paper that 90 per cent. of infants and children suffer from some derangement of the bowels arising either from dentition, convulsions, cerebral lesion, or zymotic disease; that 5 per cent. suffer from diseases of an hereditary nature, and the other five from some lesion of the respiratory organs. If this view of mine is correct (and my own observations certainly lead me to this conclusion), it shows

Digitized by Google

us how highly important it is to give the closest attention towards getting the bowels into working order compatible with health.

I have mentioned the various popular objections against calomel; the superior advantages we derive from it in comparison to the hydrargyrum cum creta; the inestimable utility of it in infantile disease; the groundless fallacy greater as regards mercurialisation resulting from it; and the likelihood of the latter occurring from the administration of its presumed superior substitute, viz., hydrargyrum cum creta. I have also drawn the reader's attention to the advantages accruing from its combination with santonin in intestinal parasitical irritation, and I have mentioned the discovery of the formation of corrosive sublimate resulting from its being combined with sugar, and the presumed danger; and I shall now make a few remarks on the advisability of administering calomel in diseases which are specially *peculiar* to infany, such as scarlet fever, measles, and others of a zymotic type.

In all the zymotic or examthematous fevers, there is the accompanying eruption or rash, as it is usually called, which, when it has thoroughly exhausted itself, or in other words, when it has finally disappeared, and the desquamation of the cuticle has commenced, then is the time to direct our attention to the alimentary canal, for we shall invariably find after, as well as during the attack, that the alvine excreta are in a most filthy and unhealthy condition, in fact, almost approaching a poisonous character, and, as some believe, contain an element highly infectious to the last degree, and especially when the patient is suffering from typhoid fever. Regarding these infectious, or non-infectious characteristics, I have nothing to do, but, parenthetically I may say, they develop gases, exceedingly offensive and injurious if inadvertently inhaled: they must therefore be extremely detrimental to the recovery of the sufferer, for if they are poisonous when ejected or exposed to atmospheric influences, what must they be when allowed to remain in the intestines, pent up in a confined space with the mucous membrane absorbing the impurities resulting from the effects of the fever, besides the impure liquid portion of the fæces; what must be the result, I say—a protracted recovery, or a certain death?

Therefore it behoves us immediately on the disappearance of the rash to administer purgatives till we have eliminated the fever poison which has been germinating and stagnating in the fæcal contents of the intestinal canal, and the only purgative which is at all capable of thoroughly cleansing out the intestines is calomel; for, owing to its dual properties, it not only purges the patient, but by virtue of its chologogic action, it cleanses out the human cesspool, viz., the liver, which, in all fevers, is a reservoir for everything impure and unhealthy.

If we do not pursue this course, the inevitable result is diarrhœa, which, instead of being regarded as a good omen, as indicating that Nature requires assistance, and that she is trying to accommodate herself to the force of circumstances, we go diametrically opposite to her, and regard the efforts of Nature as significant of approaching evil; and so we resort *instanter* to astringents, and if that is not sufficient (and it very seldom is), we inject up the rectum certain astringent compounds which is as unscientific as the insertion of a cork would be; we know, or can guess the result—the child dies, presumably from the fever, though I cannot but help thinking that the child succumbs to the deleterious action of the astringents.

Is not this method of practice almost akin to folly? Can we imagine anything more opposed to common sense? We confess that the alvine excreta are poisonous and infectious; and yet we strive might and main to enclose them in the intestines, and prevent them being jected; instead of endeavouring to eliminate the poison as quickly as possible, we take measures to prevent such a beneficial result; purgative, in my opinion, is a safety valve when the human system is struggling with disease, and especially when it presents certain characteristics indicative of intestinal deragements.

I have already adverted to this practice at some length in another part of my paper, and I shall not recapitulate it, as my remarks hold good in all the supposed different forms of diarrhœa, whether it be symptomatic or idiopathic, or resulting from dentition, convulsions, or from one of the zymotic fevers. It is all the same, in the long run, for there is the diarrhœa, or the efforts of Nature to relieve herself, whether we call it by one name or by another, whether the alvine excreta are crowded by microscopic organisms of disease, or whether they are absent. The only treatment which is at all beneficial in these abnormal conditions is the administration of such purgatives as calomel or castor oil, for by so doing we are befriending Mature by eliminating those organisms from the system, and by promoting the ejection of offensive and poisonous fæces from the intestinal tract.

It is all very well to expatiate upon the etiology of zymotic or exanthematous disease; to affirm that scarlet fever or typhoid fever can *only* arise from one particular *contagium virum*, and that the fever spreads from contagious particles which have originated from higher organisms, whether it occurs through spontaneous generation, or whether the contagia spring from ancestors after the fashion of ordinary animals; to argue upon the infectious or non-infectious nature of the excreta, and to discover certain organisms called *bacteriæ* in the blood, which appear or disappear as the disease advances or recedes in severity: we are face-to-face with one broad fact totally independent of these minutiæ, and which is generally, nay, almost invariably, present in the exanthemata, and that is diarrhœa, the turning point or crisis, which if we tamper with or treat incorrectly, all our knowledge and investigation regarding the why and the wherefore of the disease is as useless as can well be imagined: to cure the patient is our sole aim; investigating the cause of the attack should be subsidiary. But I am afraid we have unfortunately reversed this in our eager and fruitless efforts to eradicate disease, which will always be indissolubly associated with human nature.

As these minute investigations are made with the sole intent of endeavouring to stamp out disease, we can but concur in the praiseworthy efforts of those who are so engaged; but still we should exercise our powers therein with a certain amount of discretion, and not allow our knowledge to degenerate into scientific credulity, thereby mystifying our understanding, and causing us unwittingly to lose sight of the main and important object, viz., the cure of our patient. There is no doubt but that disease will last as long as the world endures, and the most scientific, sanitary, and hygienic precautions to stamp it out will be as futile as the vain endeavours of the alchemists of old to discover the philosopher's stone. We never shall, notwithstanding all our efforts, arrive at such a pitch of perfection as some hygienic dreamers long for, and prognosticate with such certainty. We must (if we wish to afford our suffering fellow creatures some palpable and certain relief, which they, in the end, will duly realise and appreciate) give greater attention towards arresting and overcoming the effects of disease, rather than devote all our energies towards discovering certain dark and incomprehensible phenomena which will never be satisfactorily elucidated; for they only give origin to specious unpractical theories, which, after occupying the minds of the ingenious for a short period, give place to others, even, perhaps, more complex and mystifying. Vain theoretical speculations do for the subtle casuist; but, matter-of-fact, truisms must be the goal of all those who wish to arrive at the perfection of medical science, and the only roads leading to it are simplicity of treatment, accuracy of observation, and by discarding certain far-fetched hygienic and pathological hypotheses, which confuse and mislead those who are too credulous to doubt, or too indolent to investigate.

Digitized by Google

We have thus seen that in all fevers the most important part of the treatment is the administration of purgatives, though I am aware that this is not the received opinion of the present day. However, there is one fever belonging to the zymotic class, about the treatment of which there is not such a great diversity of opinion as there is regarding its origin and contagious character, and that is, typhoid, or as it is sometimes called, enteric fever.

I do not intend discussing the much vexed question of its origin, whether it arises from milk or excreta, whether it is contagious or non-contagious; my object is to see if we cannot arrive at some definite and practical mode of treatment, and especially regarding the administration of calomel.

In the premonitory stage of typhoid fever, we have the usual symptoms indicative of a febrile condition, which we very often see in patients who are suffering from the pernicious effects of prolonged constipation through overeating, inactive habits, and inattention to the bowels. I have noticed this marked similarity of symptoms frequently, and I am sure that some of my patients (when the diarrhœa had commenced owing to the inability of the intestines to contain their contents) would infallably have dropped into that condition called typhoid fever, had the administration of calomel not been resorted to.

We find that the premonitory symptoms are chilliness, offensive breath, a dry furred tongue, loss of appetite and nausea, bowels constipated and irregular, and the urine loaded with phosphates; and there is also a pain in the back. These are the principal symptoms which are quite sufficient for our purpose, pointing decidedly to bowel disorder, and would be speedlly rectified by the administration of such a purgative as calomel. This simple treatment, however, is overlooked, and consequently, the patient gets worse, and by reason of this abnormal condition of the bowels being unattended to, the patient sooner or later, according to the degree of strength he possesses, succumbs, and typhoid fever results, which very likely is ascribed to invisible germs, to milk, or to some infectious excreta, or to something else equally difficult to disprove. However, it is easy to see, as I have said before, that the symptoms point to bowel complication, and we shall find further on that they increase in intensity, owing to the fact that the administration of purgatives is entirely neglected. In the first week (for this fever is divided into different stages) there is great nervous depression, the pulse increases in frequency, there is extreme thirst and heat, the patient complains of pain in the head, accompanied with giddiness, and now the diarrhœa commences, and we get the famous typhoid stools; the abdomen feels full, and in some cases tense and painful, and we become aware, on pressing the right iliac region, of a gurgling sensation which is communicated to the finger.

Now we have got at the root of matter, and, in my opinion, to the origin of the fever: first, we have constipation, turbid urine, foul tongue, offensive breath, and very frequently, the pain in the back, indicative of an overloaded transverse colon; secondly, we get thirst, nervous depression, great heat, pain in the head and giddiness; and finally, diarrhœa, or the efforts of Nature to relieve herself: also there is a gurgling near the ileo-cæcal valve which is detected on pressure.

(To be continued.)

THE rates of mortality per 1,000 last week in the principal large towns of the United Kingdom, were—Oldham 13, Edinburgh 14, Norwich 15, Sheffield 16, Leicester 16, Glasgow 16, Bristol 17, Portsmouth 17, London 17, Newcastle-on-Tyne 17, Bradford 17, Plymouth 18, Birmingham 18, Hull 19, Wolverhampton 19, Sunderland 20, Leeds 20, Salford 22, Dublin 24, and the highest rate 26 in Nottingham, Brighton, Manchester and Liverpool.

Clinical Records.

MERCER'S HOSPITAL.

Some cases under the care of Mr. F. ALCOCK NIXON,

Fellow of the Royal College of Surgeons; Lecturer on Surgical Anatomy in the Ledwich School, Peter Street; Surgeon to the Hospital.

Primary Amputation of Leg immediately below the Knee by a Long Posterior Flap.

J. K———, æt. 20, conductor of a tram-car, while on duty for the first time, slipped off the front step of the car, both wheels of which passed over his leg, cutting off the entire skin on its antero-lateral aspect from the tubercle of the tibia to the ankle, lacerating the muscles and vessels, and severely comminuting the bones. When seen a short time after his admission he was in a state of collapse, his features pinched, his eyes sunken, the surface of the body covered with a cold clammy sweat (indicating the effect of the injury on the sympathetic system), shallow respiration, moaning, and restlessness, with relaxation of the sphincters pointing to the sympathy of the cerebro-spinal axis. From this condition he was rallied by the internal administration of ammonia, hot jars in the axillæ, mustard sinapisms over the heart, and on consultation with my colleague, Mr. O'Grady, who kindly saw the case for me before I reached the hospital, amputation was determined upon in the ward, the patient being too weak to be moved into the theatre.

When under the influence of chloroform, a straight incision was made across the limb below the tubercle of the tibia. The skin below that point, as already mentioned, having been removed by the wheels, and a long posterior flap was made by transfixion, the fibula and tibia were divided, the edge of the latter bone was carefully rounded, the periosteum having been previously pushed up, considerable difficulty was experienced in securing the posterior tibial and peroneal vessels, owing to their retraction into the soft tissues, and partially to the fact of the operation having been performed by candle-light. A strip of lint steeped in carbolic lotion having been placed in the wound for drainage, the parts were secured by carbolised cat-gut suture, and an opiate administered. The patient passed a restless night. In the morning he was greatly flushed. The secretions were vitiated, and partially arrested. Temp., 104·5 F.; pulse, 120, very full and bounding, pointing clearly to the danger of intermediate or reactionary hæmorrhage, to guard him against which he was ordered 5 minims of tinct. aconitæ, and minim doses every ten minutes for two hours, at the end of which time the pulse was less full and frequent, and the temperature lower. Occasional doses were administered during the day by the Resident Medical Officer, Surgeon Canton, as he thought necessary. The pyrexial condition gradually passed off, and his convalescence, though slow, was fairly steady, it was delayed by a sharp feverish attack, due, I believe, to erysipelatous poison germs floating through the ward; also by slight necrosis of the anterior part of the tibia and protrusion of the fibula through the posterior flap (the protruding part was subsequently removed), as well as by the fact that there was a large surface in front to heal by granulations. The motion of the knee-joint is in no way impaired by its long inaction, and the patient has been discharged from hospital after a residence of more than four months. A lengthy period, no doubt, but all things considered, not excessively so.

The case was an unpromising one, statistics of amputations performed under similar circumstances showing a high mortality. It was impossible to operate by the circular incision, so the method adopted was on the principle of "cutting a coat according to the cloth," the object being to preserve, if possible, the knee-joint, no matter how tedious the convalescence might prove.

A Large Number of Polypi (Fibro-Myxomas) obstructing both Nostrils.

J. D———, æt. 22, came to hospital with well-marked symptoms of nasal polypi. She noticed some time before that she was very liable to catch cold. She suffered considerably from catarrhal symptoms, sneezing, &c.; later on the nasal respiration became considerably obstructed, her eyes, as

Digitized by Google

she expressed it, "watered." On examination. a puffiness was noticed at either inner canthus, especially the right, and the tears flowed—symptoms due to pressure of one of the polypi on the nasal duct, and which disappeared upon its removal. The respiration was almost altogether oral; tumours of a white starch-like appearance presented themselves at either nostril, and occasionally, the girl said, came down in damp weather; her voice had acquired a peculiar nasal tone, and there was considerable lateral displacement of the nasal bones producing the well-known frog-like appearance of the face. The tumours grew principally from the inferior and middle spongy bones; some small ones were attached to the roof, but the septum as usual was free. The application of powdered tannin having produced no result, some of those which were pedunculated were snared and slowly twisted off; others sessile, were removed with a long curved flat-bladed forceps; in one instance, a larger one covered with thickened mucous membrane, with several small ones, transparent, of a yellowish colour, clustered round it, was removed with the portion of the bone from which it grew. There were from time to time sixteen large polypi removed; they were myxomas with a fine fibrous stroma, the epithelium on their surface was of the ciliated variety; the fibrous stroma was found in some instances directly continuous with periosteum of the bone, a fact which shows that the removal of a portion of bone with the polypus is rather advantageous than otherwise, and tends to prevent its recurrence.

The patient was discharged with each nostril free. She was to have returned if she felt any further inconvenience, but has not since been heard of.

Excision of Elbow-joint.

J. B———, æt. 14, a weakly lad with cicatrices of strumous abscesses in the neck, and other evidences of delicacy, was admitted to hospital with a small cold abscess over the external condyle of the humerus and slight stiffness of the joint. There was no definite history of injury. The abscess, in spite of treatment, "pointed," and was opened, discharging a straw-coloured fluid, with curd-like flakes floating in it. The wound did not heal kindly, the skin sloughed, leaving an unhealthy ulcer. A prominent exuberant granulation shortly presenting on its surface, a probe passed down the sinus which it marked struck dead bone, all efforts to procure exfoliation, of which, by natural processes, proved useless. The joint became puffy, of a dull white colour, doughy, or semi-elastic to the touch, and stiff on active or passive motion, owing principally to rigidity of the neighbouring muscles. The disease commencing in the bone had evidently spread to the synovial membrane; so the total disorganisation of the joint was merely a matter of time, and as it was manifest that any attempt to remove the sequestrum, even if successful, would result in ankylosis, excision was determined on. The boy having been brought under the influence of chloroform, a straight incision, about 5 inches long, was made over the inner side of the olecranon process; the soft tissues, with the ulnar nerve, which did not come into view, were worked over the internal condyle; the ligaments were divided, and the joint, which contained a slight excess of synovial fluid, laid open; the synovial membrane was found thickened and injected. The olecranon process and head of the radius, with their cartilages of incrustation, though healthy, were removed; the end of the humerus was cut above the infra-condyloid line; the limb was put up in the straight position with an anterior splint, and as repair went on it was gradually flexed, passive motion being set up at an early period. He got up with his arm bent in a sling six days after the operation. The wounds are healing rapidly, and the patient promises to have every motion of the joint complete—a result due in a great measure to the care bestowed upon the case by Mr. O'Grady, who was good enough to take charge of it during my absence from Dublin.

An examination of the lower end of the humerus showed the part of the epiphysis, which goes to form the external, to be the seat of cario-necrosis, the disease had passed downwards and implicated the cartilage covering it, inducing granular degeneration of it. It is therefore evident that no other treatment but excision would have been of any avail.

Extensive Syphilitic Disease of the Nasal Cavity.

M. S———, æt. 35, contracted syphilis from her husband nine years ago. Within a year she gave birth to twins (still-born). From her account of her illness, she appears to have suffered from syphilitic fever about seven weeks after noticing the primary sore, and on examination on admission was found to be the subject of visceral syphilis. She had copper-coloured stains on the skin and some patches of psoriasis, cicatrices of phagedænic ulceration on the tonsils and soft palate, periosteal thickening of shafts of some of the long bones. Some of the superficial vessels were atheromatous; there was slight hepatic enlargement, and she had lost flesh, and suffered from other symptoms of syphilitic cachexia. She had well-marked ozæna, the lining membrane of the nose was extensively ulcerated, the hard palate was fissured, the spongy bones were attacked by periostitis, and gradually came away, the nasal bones and the superior maxillary (its nasal process) were similarly affected, and became flattened. The syphilitic inflammation travelled up the nasal duct, implicated the lachrymal sac, and caused an overflow of tears which produced excoriation of the cheek; the alæ nasi were inflamed, of a glazed-red colour, and ulcerated. She was treated with nasal douches of weak solutions of carbolic acid and Condy's fluid as there was great fœtor, and the local application of calomel dusted into the nose off a camel's-hair brush; this, one morning, caused sneezing, and the discharge of the vomer. She was ordered internally—

Hydrarg. perchloridi, gr. i.;
Pot. iodidi, ʒij.;
Tr. calumbæ et syrupi aurantii aa ʒj.;
Inf. calumbæ, ad ʒviij. M. h. v.

A tablespoonful three times a day.

But when commencing the second bottle of the mixture she was profusely salivated. She was then ordered pot. chloral and bark, beef-tea, and port wine, under which treatment the effects of the mercury passed off, and her health improved considerably, and she was advised to go to the country for change of air.

The case appeared worth noticing from the fact of salivation being produced so rapidly by so small a quantity of mercury, showing how thoroughly her system must have been previously saturated (though she stated she had not been under treatment for months), and also how readily a broken mucous surface will absorb a substance which may, with impunity, be applied to it in its healthy condition,

Special.

PAUPERISM AND COMPULSORY PROVIDENCE.

I.

THERE is a well-known story of a Frenchman who, on being asked by some one in authority, why he had written a certain infamous lampoon, replied: "*Monseigneur, il faut vivre!*" to which the great man retorted: "*Je n'en vois pas la necessité!*" Monseigneur could not understand why the Parisian should not starve, or even die; there would be no loss to the country by the death of a wretched lampooner. But the hack evidently did not see matters in the same light as the great Minister of State; and so he wrote, in order that he might live.

At the present time there are a great number who believe there is no necessity for pauperism, and we heartily wish that they were right, and that our poorhouses, and out-door relief, our charity organisation societies, and our hospitals, our clothing clubs, and the rest of such pauperising media, could be all done away with, and pauperism could be swept from the land. Can we extract sunbeams from cucumbers? A philosopher thought such a thing was possible. It has not yet been accomplished. Can we sweep indigence from off the earth? An economist of the present day thinks such a scheme feasible. But looking at the world as we find it, we fear that we shall have to wait for the first cucumber-sunbeam before we shall see the realisation of the dream of the modern economist. We, however, wish him God speed; and for that purpose we shall introduce his scheme to our readers, as they are largely interested in pauperism and its effects.

Our existing Poor-laws were condemned by Malthus, who declared (v. ii., p. 149) that they had not only failed in their object, but that they have been productive of much

Digitized by Google

more wretchedness than would have existed without them; though they may have alleviated a little the intensity of individual misfortune, they have spread the evil over a larger surface. Our experience of the Poor-law system would go far to confirm Malthus' position. Pauperism is more widely spread than ever, and our poor rates are swelled to meet the excessive demands of the indigent, but unfortunately, both the deserving and the undeserving reap the benefits of the Poor-law provisions, for in our so-called workhouses they are herded together indiscriminately. The agricultural labourer who, from his scanty wages, cannot save a pittance for his old age, when he is past the age for work, is shut up with the vagrant and the ne'er-do-well; and similarly with the mill operative. A pauper's grave marks without distinction the remains of Giles Chawbacon, who for over forty years helped to advance the agricultural interests of England; of Simon Yarn, who also for thirty or forty years, as a spinner, helped to swell the manufacturer's profits; and of Reuben Spendall, who never worked as long as he could beg. All are condemned to the same ward in life, and the same narrow six feet of earth in death, thus enforcing the lesson of the preacher —*vanitas vanitatum*. It is difficult to alter this. Most economists say that the man who has saved up nothing when young is not entitled to an annuity when old. Can the ordinary labourer save, for destitution in sickness, and for old age? If a man has paid poor rates for thirty or forty years to support other people, is he not entitled to throw himself on other people's poor rates when he is old, and no longer able to pay rates or to keep himself? Do the labourer's wages really represent the value of his labour to society?

These few questions will at once show how difficult the question is, and from how many sides it may be considered. At present we need not linger on them, but shall at once proceed to Mr. Blackley's suggested remedy.

In 1878 Mr. Blackley published an essay under the title of "National Insurance," in which he indicated a possible means of vastly diminishing our poor rates and the pauperism, which they promote as well as relieve, by making every unit of the population, at a reasonable cost and by a reasonable method, personally independent of parish relief in the time of sickness and old age. This he proposed to accomplish by means of a National Benefit Club. In other words, his plan amounts to this, that every unit of the nation shall make his own provision, *with his own money*, against destitution, and shall make it in such a way that every man for the same sum secures the same provision for himself as every other man; the whole function of the State in the matter being to act, by consent of the nation, as collector of each man's own insurance fund, and as banker of that fund when once collected.

In the July number of the *Contemporary Review*, 1879, he has defended his scheme against a number of objections which have been raised against it. One class of objectors say Government should not incur so much additional responsibility; this would be a poll tax or a poor rate under another name. To which Mr. Blackley replies, Government will have no money responsibility; but he denies the analogy between his system and the Poor-rate, defining the Poor-rate as a compulsory provision by the provident or by the provided party for the improvident and unprovided party; whilst the National Club would be a compulsory provision by every unit of the community, *for his own needs*, not for other people's destitution.

Other opponents of his system urge that the National Fund would be created mainly by compulsory contributions from persons having no right to share in it; to which Mr. Blackley is ready with the answer that this is an entire mistake, for the person entitled to receive it need not be destitute at all. He might own a house, or half-a-dozen, have money in the bank, and money in his pocket; and still, as a wage earner, be able to claim his own full pay. He differs thus from a pauper, as he is self-provided and independent—thanks to his own, or rather to compulsory, providence.

Another objection is conveyed in the old-world formula, so familiar to those who are interested in Sir Wilfrid Lawson's measure. It is thus conveyed: People cannot be made good by Act of Parliament. Compulsory thrift! How can it exist? There is no virtue in a man saving against his will. Thrift and providence will be made disgusting to those disposed towards them; and as for those averse to them, greater harm will be done. These worthless arguments are disposed of by Mr. Blackley, who well replies: Whether people can be made good by Act of Parliament has nothing to do with the question; he never said they could. Whether compulsory thrift can exist is equally irrelevant. He speaks of compulsory providence, which is a different thing, and which can exist. Whether there be virtue in a man saving against his will he need not answer, as he never said there was; and as regards the latter assumption, that thrift would become disgusting to the already thriftily disposed, he challenges the assumption as absurd. He quotes a favourable statement from the proprietor of a provincial paper, to show how his proposal was received by working men. The writer says: "You will be pleased to that learn our article on your plan sold nearly 1,000 extra copies of the ——— last week, and that the principal purchasers were Oddfellows and Foresters. My friends here are all delighted with the project." Another charge against his system is thus formularised. The scheme would lead people to look to the State to do for them what they should do for themselves. Mr. Blackley exclaims: Heaven forbid! that is exactly what they are doing now. It is the iniquity against which I protest, claiming that the law should make people do for themselves what they now expect the State to do for them. Another objection is couched in these terms. The very simplicity of the scheme arouses suspicion. Mr. Blackley has little difficulty in disposing of this objection. He says: "The thing is so simple to me that I never thought of making it complex to other people. As a wise school-boy when being caned rushes into his master's arms to get the minimum of hurt, I come to close quarters with this unexpected objection, which I certainly cannot refute, and simply say the suspiciousness is a reason for examination, not for rejection; and that the simplicity, so far as it goes, makes altogether in favour of the scheme."

Space prevents us at present entering on further objections, to which we shall devote another article. We shall conclude with a citation from another critic, who thus expresses himself, so that Mr. Blackley may congratulate himself on having at least one favourable and hopeful critic:—

"If the scheme has its difficulties and drawbacks, on the other hand, it has its advantages. These consist in its simplicity, economy, and the directness with which it effects the object. As a remedy against adult pauperism it is well-nigh perfect, as it is obvious that you have only to provide for a man in the helpless times of sickness and old age; and you have done all that could be done for him, by even the most indulgent of poor-laws."

Department of Lunacy.

COMMISSIONERS IN LUNACY ON PRIVATE ASYLUMS.

THERE are few subjects which have caused so much discussion during the year as private asylums. Various Bills have been brought before Parliament relating to insanity, having as their basis the abolition of these institutions either by purchase by the Government or by total annihilation. It may be fairly asked on what grounds the clamour for this has been made. This question is easily answered. It is in consequence of a certain class of society who are biassed by false reports and rumours and garbled statements relating to private asylums, but which are quite unsupportable and unauthenticated, and made by some *would-be* reformers in lunacy. The public mind has been severely prejudiced by these reports, and it is a great satisfaction for us to read the remarks of the Commissioners in Lunacy on the subject, and we accept them as coming from the only persons who are entitled to speak with any authority on the question. We read as follows: 'A system which places the insane

Digitized by Google

in charge of persons who derive profit from their detention, is no doubt objectionable in theory; and in practice (like many other things) may be open to abuse. But so far as regards the licensed houses in England and Wales, which alone come under our observation, we are convinced that, under the strict supervision and the safeguards which the Lunacy Acts provide, no such abuses are possible as have been in some quarters seriously alleged, such as the 'incarceration' of sane persons, or the prolonged detention for corrupt motives of insane persons who have entirely recovered their reason. Nor are the proprietors of licensed houses open to the sweeping charges of dishonesty and self-seeking which have been brought against them as a body. It should not be forgotten that these persons to some extent are competing with each other and with the hospitals in a business which, to be remunerative, must be conducted on principles of ordinary prudence and common honesty." This is a contrast to what a contemporary styled proprietors of asylums, such as "adventurers," men without any feelings for honesty or humanity, individuals whose sole desire is to get what they can out of those mentally afflicted without endeavouring to "minister to a mind diseased," and persons practising in a dishonourable calling.

We have so frequently given the statement as to the "alleged detention after recovery" a denial, that it is satisfactory to find our testimony is substantiated by the Commissioners. We also read that "the licensed houses supply a social want," and that their abolition "would assuredly multiply cases of illegal charge and consequent neglect and ill-treatment of lunatics." The Commissioners cannot endorse the suggestion of erection of private asylums at the public cost, and quote the conclusions arrived at by the Lunacy Committee as bearing on the point: the number of metropolitan asylums is thirty-nine, and provincial sixty, all licensed for the reception of private patients. The Commissioners appear to have taken considerable pains to ascertain the amount paid for the inmates confined in private licensed houses. We find that in thirty-two of these houses receiving about 1,300 patients, the average payments are at the rate of £100 per annum; in twenty-two private asylums, which receive about 750 patients, the average cost is from £100 to £150 per annum; in the remaining thirty-five houses the charges are higher, ranging from £150 to £470, including carriage exercise and other luxuries. We know as a positive fact, that in many instances the actual payment made does not cover the expenditure of the patient. The Commissioners also draw attention to the circumstance that in many asylums relatives of the patients reside, and this is considered by them a very desirable move, and one to be encouraged.

In a subsequent article we shall allude to the remarks made in the Commissioner's Report on the "Lunacy Laws."

A BUST of the President of the Queen's College, Belfast, has been placed in the consulting-room of the Samaritan Hospital for Diseases of Women, Belfast, being the gift of a former student of the College.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 8, 1879.

THE OPENING ADDRESSES.

THE Medical Session, 1879-80, was opened on the 1st inst. by addresses at several schools; Guy's and the London following the example of St. Bartholomews by refraining therefrom. What may be their reasons for this we do not profess to know; nor is it a matter of much interest. The bulk of the metropolitan schools have adhered to what has now become customary. Certainly it may be urged that the formal opening of a school brings old students and their teachers together; and admits of the freshman seeing who are going to be their instructors, and of what manner of men their *collaborateurs* are. The opportunity is a favourable one for addressing words of counsel and advice to those who are commencing their studies; often with very slender acquaintance with what they will have to learn, and how to systematically start about their studies. Mr. Keightley's pamphlet will be more or less familiar to many of them; but probably others have not seen it, and the introductory address is the first formal announcement to them of what they must do, and how they may best set about doing it. However little novelty any lecturer may be able to throw about his address, a certain amount of solid and valuable advice can thus be given to the newcomers. Nor need their seniors necessarily feel bored by listening thereto. Probably many feel that if they, in the early years of their studies, had followed more eagerly the advice tendered to them, they would have been all the better, and none the worse, of it. Perhaps if they had

Digitized by Google

accepted the advice some troubles might have been avoided.

The addresses, after this stock matter has been disposed of, moved in various directions. At King's College, Dr. Duffin went into the question of the pathology of pyæmia, and then with natural pride in his school, referred to what Professor Lister had done in the way of its prevention and treatment. The reception which greeted Professor Lister at the recent International Medical Congress at Amsterdam, quite justified Dr. Duffin's eulogy of his colleague. Some old practitioners will, however, read the statement made about pyæmia—that we are "now in the position of victors over this dreaded foe, the fearful ravages of which long since became a matter of national importance, and had proved the curse of many surgical hospitals"—with a sense of satisfaction, blended, perhaps, with some scepticism. Whatever Professor Lister has done for our hospitals, he has done infinitely more for those on the Continent, where his plan of treatment has completely revolutionised surgical practice with the most beneficial results. After that, Dr. Duffin discussed the subject of the opposition offered in England to experimentation on animals, and the recent Vivisection Act. We think he met the oft-asserted charge of deliberate cruelty in the insensate and useless infliction of pain by medical men, which figures so conspicuously in the mendacious and rabid clamour of the anti-vivisectionists, very satisfactorily, by pointing out how the medical profession had worked at anæsthetics; and how they had succeeded in performing the gravest and most difficult operations without the slightest pain or suffering to the patient, whether human or brute.

At St. Thomas's, Dr. Cory also discussed the Vivisection Act, which he said was "unjust, and should be repealed, as it was passed in the face of the evidence collected by the Royal Commission." The whole history of this irrational persecution of physiologists is a subject which will form a curious chapter for some future historian. Dr. Cory said, "Almost all those who had advanced the knowledge of their profession had practised vivisection, and it was by means of this practice that they to a great extent had succeeded." This statement is calculated to create a false impression in the public mind, or rather to foster the false impression already existing, viz., that vivisection is or was largely practised among the members of the profession. Yet very few members of the profession ever saw an experiment performed on a living animal; and if those who have advanced the knowledge of the profession are confined to those who have performed experiments on animals, their numbers are remarkably few; how few, the public have no idea, and probably could not credit it if they were told.

At University College Hospital, Prof. Thane reviewed the history of his hospital, of which he is justly proud. There was the first chair of Pathological Anatomy instituted in this kingdom. The first regular courses of clinical lectures were delivered there by the great Robert Liston. What was still more meritorious, there was set the example of throwing open the offices of dresser, clinical clerk, and house-surgeon to competition; in preference to the plan of requiring large sums of money for them, which had hitherto obtained. He then referred to the very large amount which had been given to this charity by its medical officers.

At Charing Cross Hospital, Mr. Hird referred to two old students of the hospital, Mr. Jolly and Mr. Conolly, who had served in the recent war in; Zululand and whose behaviour in operating under fire, had gained for them honourable mention in the military dispatches. He then pointed out the unsectarian character of our profession; its broad sympathies; and its impartiality to political and theological differences: how, when properly carried out, the daily vocation of the medical man evoked the best emotions of our nature in striving with pain and suffering.

Then several lecturers addressed themselves to the subject of the form medical study should take; and the diversities of the views expressed are instructive and suggestive. At Westminster, Dr. Dupré discussed the claims of the two opposing schools—the technical and the classical. On the ground that education should not be limited to certain periods, but be progressive during life; he favoured the classical school. "In England," he said, the "advocates of technical education were gaining ground: while in Germany the battle had been fought out, and the victory was more or less, with the classical school. He hoped such would be the end of the struggle in England. In separating more completely than was done at present, the scientific from the practical, the student, would on the one hand, gain time for the more minute study of the natural sciences, to the great advantage of his intellectual training; and on the other hand, when once he began his real professional work, his time would be no longer taken up with the study of what were after all, auxiliary subjects." Certainly, it is to be devoutly wished that all medical students should have had a thorough intellectual training before commencing their medical studies; but as we pointed out last week, this is hardly feasible, or practically attainable. Mr. Dalby, at St. George's, also said, "Mental training must be a valuable addition to any course of education," and its value is unquestionable; but how medical students are to acquire this before commencing their studies it is not easy to see. That those men who, more mature in years, and with minds already trained to think, learn more and profit more by their course of medical study, than do younger men with less trained minds, is well known to all.

At St. Mary's, Mr. Mivart spoke at length about metaphysics, "the importance of arriving at a decision when sufficient data were attainable to prove a correct idea as to the probable result. That really was but methodical common sense, and no greater service could be done a young man than to show him a way out of speculative and dangerous theories." That such power to see his way through specious fallacies and unsound inductions would be of immense service to a medical student, cannot be denied. Further, it would be a priceless boon to many students if they were systematically taught how to reason on the cases presented to them; how to rationally approach the investigation of the different phenomena of a case, however simple. Logic may be part of the preliminary examination for entrance upon professional study; but how to reason accurately on a case is one of the rarest possessions of young doctors in our experience. If they were taught the different steps and stages of a common cold, and the treatment appropriate to each stage in a rational manner; this would be of the greatest value to them in after life. That a metaphysical training, something analogous to the Scotch

Digitized by Google

Arts' course preceding medical study, would be of service to our English students, may not be questioned: but when it will be achieved is a matter for doubt.

At the Middlesex, Dr. Coupland gave some very good and timely advice to the new men. He insisted upon steady industry, and told them that if they were not ready to work earnestly they had better abandon medicine for some more congenial and less exacting vocation. Probably in saying this, he bore in mind that the present depression in trade and agriculture has made many young men turn to medicine, who otherwise would have entered the ranks of commerce, or become agriculturists. Young men who are on the outlook for a comparatively easy life, with a fairly good social position: and whose female relatives are heard bewailing the severity of examinations, and the smallness of the mesh of the net which is instituted to protect society at large against dangerous ignorance: who do not realise the fact that the examinations which are essential to the attainment of a diploma, after all are only minimum tests, requiring such information as a man must possess; and that they do not necessarily indicate any very advanced knowledge. At this time, then, the remarks of these various teachers about a proper education, and a fair mental training before a course of medical study is commenced, are well-timed and seasonable, and ought to be of much value to the youths to whom they were addressed. Dr. Coupland pointed out how hospitals devoted to medical teaching were of value, not merely as affording succour and relief to the sick poor, but as the means by which medical education could be carried out for the benefit of society at large. There is something more in the study of medicine than merely a genteel way of making a living; a medical man has a sacred trust placed in him, which should put him on his honour. When a patient places his life in a doctor's hands, this very act of confidence should, in return, call out from that doctor a corresponding sense of right to that confidence—the feeling that he should not be unworthy of it. If from an ignorance, which is removable by industry and painstaking, the life of a patient is sacrificed, then it is a breach of trust an the doctor's part of a most discreditable character. When a medical man is called in to see a patient it is not merely an evidence of the patient's belief in him; but it is an act of confidence which the doctor, as a man of honour, should not abuse. The reputation of a profession is the aggregate of the reputation of every single unit of it. Every man entering the profession should honestly commune with himself as to how far he intends the medical profession to float him in the world; and as to how far in return he means to do honour to his profession, and to give something in return for what he gets. He may never attain distinction, nor make very valuable additions to our knowledge; but he may set the example of a blameless life, of conscientious painstaking to the best of his ability; be a man first, and then if possible further a gentleman, in the true sense of the word, respected and trusted by those who know him best. By such self respect he raises himself in his own eyes, as well as in those of others; and further he does credit to the profession to which he belongs. It is on the attitude of every unit in it that the reputation of the profession rests; and every man must be watchful, and see that he make the best use of the knowledge he possesseth; and that he is a good and faithful servant, who has made a good use of his talent; that he is an honourable unit in that profession—one who returns what he can for what he has got; and that he be not in the end an unprofitable servant, who has lowered his profession in seeking his individual advantage. And at the present time such self-communing is especially desirable; and the remarks of the various lecturers are peculiarly appropriate.

THE DUBLIN SANITARY COMMISSION.

The inquiry into the causes of the excessive mortality of Dublin has been pursued during the past week by the Commissioners, Colonel Rawlinson and Dr. MacCabe, and has inspired the citizens of Dublin with a hopeful confidence in the tribunal, and in the result of its labours. The very grave apprehension which we expressed last week, that the investigation, being limited to the effect of the Liffey, would be quite useless as an elucidation of the real causes of the high death-rate, has, we are happy to say, been to a certain extent dissipated, for we recognise an obvious anxiety on the part of the Commissioners to probe to the bottom the sanitary sores of the city, and to avail themselves with freedom of the evidence of those who know most of the subject. In his initiatory remarks the Chairman said they were instructed to inquire into the main drainage and the purification of the Liffey, but, inferentially, he held that they were not debarred from taking into consideration other causes which might affect the public health of the city of Dublin; and that there were other causes of a very grave and serious character he was sure every person who had paid the slightest attention to the condition of Dublin must be perfectly aware. There were many theories as to the causes of disease in excess. Some attributed the excess to geological causes; some to meteorological causes, and so on. He had been obliged to come to the conclusion that the prime causes were not to be attributed to those conditions, but to some form of neglect in the construction and management of the houses in which the people dwelt. If they had people living under conditions where purity of the atmosphere was impossible, they must naturally look for excessive disease; and where those conditions existed it was the duty of the sanitarian to make such recommendations as would lead to their removal, and he hoped that the report of the Commissioners would contain practical recommendations which, if followed, might tend to the future benefit of the city of Dublin.

We are unable to devote to the subject space sufficient even for an epitome of the evidence, but we cannot pass by the testimony offered to the Commission without pointing out that each consecutive witness confirmed with more emphasis the opinion which we have frequently expressed, that the state of the Liffey, though undoubtedly a factor in the excessive mortality, was not a very important one, and that the real *fons et origo mali* lies in the utter abomination of the tenement houses in which the working classes of Dublin dwell; the palpable inefficiency of the public scavenging under the Corporation, and the total neglect of the domestic scavenging by that body; and the universal imperfection of the house drainage system. The

Digitized by Google

revelations respecting the tenement houses of Dublin must be difficult of credence to our English readers.

The City Engineer said he was sure the house drains constructed under the direction of the Corporation were all right, but that did not amount to one half or one third. For instance, in Mountjoy Square, out of 59 or 60 houses there were only 17 houses had proper drains. Any sickness that occurred in the district was not owing to the main sewer, which was as sweet as that room, but from the defective house drains. A very considerable proportion of the best class of houses in Dublin are as defectively sewered as the poorer ones.

The Chairman said the tenements of Dublin were just as bad as it was for places to be in which human beings were supposed to reside. At the same time he must say he had not seen anything worse in Dublin than he had seen in what was called rich England. It was impossible for language to describe anything worse than certain portions of the tenement districts of Dublin. The houses were not fit for animals, let alone human beings. They were not worth one year's purchase.

Mr. James Boyle, Secretary to the Public Health Committee of the Corporation, in answer to Dr. MacCabe, stated that he had made a classification of the houses in the city. Of those rated under £10 there were 4,000; over £10 and under £20, 6,000; over £20 and under £45, 9,000; of those over £45 and under £75, 4,000; and of those rated at over £75 there were 962. The total number of inhabited houses in Dublin was 23,830, and the average number of inhabitants to each house was thus 10. The tenement houses extended to the three first classes, but the number of tenement houses rated above £30 and under £45 was very small—only about 400. The total number of tenement houses in Dublin was 9,760. Rather more than one-third of the tenement houses in Dublin were in the class of houses rated under £10. The average density of population over the area of the city of Dublin was 65 per acre, but there were portions of the city where the density was much greater. For instance, he had discovered areas where the density reached so high a figure as 242 per acre. These were chiefly tenement houses. The number of inhabitants in each tenement house was generally about 13 or 14, but in the year 1866 he had discovered a house in Church Street—No. 136—which was occupied by 78 persons. It had been calculated that the cost of carrying out a proper system of domestic and public scavenging would be £30,000 or £40,000 a year. The public scavenging of the city at present cost £12,000 a year, and it was imperfectly done. He had been called in to inquire into the state of some of these houses and had discovered a state of thinge for which he was quite unprepared. It was intended to make a house-to-house inspection of eacn house in the city, with a view to find out the real state of their sanitary arrangements, and with a view of pointing out to the owners the necessary remedies that required to be effected. The causes of the high death-rate in Dublin were the class of dwellings, the saturation of the soil upon which the houses stood with organic matter for a period of 150 or 200 years, and the defective amount of air spaces in many parts of the city.

The Registrar-General, Dr. Grimshaw, said he was inclined to say that a very small proportion of the excessive death-rate of Dublin was attributable to the state of the Liffey between the quay walls. He believed himself that the effect of the effluvium arising from the river foreshores upon the health of the city was inappreciable. He believed the house drainage of Dublin to be excessively bad, and was sure that in a large proportion of cases it had a very injurious effect on the public health. He was afraid that applied to all classes of houses. There was nothing that could be called a system of filth removál in Dublin, like such as existed in England. He had no doubt that an organised system for the removal of house refuse at short intervals would be of the greatest advantage, and would tend more to improve the health of the city than anything else that he was aware of, while he doubted that it would cost more than what was at present paid for the removal of house refuse. He roughly calculated that the cost to the city of a systematic cleansing of ashpits would be about £30,000 a year. When the Act of 1874 was passed the Sanitary Association called on the Corporation to make proper provision for the cleansing of ashpits and the removal of house refuse, but the Corporation refused to alter their existing arrangements. The ordinary sanitary arrangements, such as the removal of house refuse and so on, are a very serious matter in considering the health of a city. The streets of Dublin are not sufficiently scavenged, and another element is the system of allowing filth that has been removed to accumulate within the city. Many ashpit cleaners have what they call manure yards, where they mix the various materials that they collect. I am sorry to say that the Corporation themselves have got two or three of the biggest manure yards in Dublin. Refuse is collected in the streets, and brought to depots within the city, where it is sold to farmers. Again, the arrangements for removing patients to hospital are very imperfect. I believe all these deficiencies are chiefly to be attributed to the difficulty of getting funds to pay for the remedying of the evils. Slaughter houses also are scattered through the city, and the cowsheds and dairy yards are very great nuisances.

Mr. Rawlinson said with regard to the street scavenging, although they had fine weather since they arrived in Dublin, he saw the street sweepings were allowed to accumulate along the footpaths, and he presumed from that that the scavenging power was not sufficient.

The City Engineer said it was a fact—the scavenging power was totally insufficient, and had been so for years.

Mr. Rawlinson said it was a blundering and costly way of doing the business twice over, for the mud, when allowed to remain along the footpaths, was splashed over the passengers, or ground down and scattered before it could be taken away.

We cannot pursue the evidence further, although the same testimony was given by the medical officer of health, Dr. Cameron. There would seem to be a consensus of opinion that the city is in all respects disgracefully kept, not cleansed or inspected, and that whoever has been chargeable with the duty of remedying such a condition of affairs have grossly neglected their business. We don't entertain a doubt that the means of doing so, both legal and financial, either existed already, or might easily have been procured by an energetic and earnest executive, and we trust that the light which the Commission has thrown, and will yet throw upon the subject, will, for the future, make impossible such indefensible negligence.

THE RELATION OF THE STATE TO MEDICAL EDUCATION.—I.

In all civilised countries the State has recognised and accepted the duty of restricting the practice of medicine to competent persons, and has, therefore, found it necessary to interfere in the regulation of the education of medical men to a much greater extent than with reference to other professions. The primary reasons for this interference are fourfold:—

Firstly, that the life and health of the subject is of essential value to the community in which he lives, and upon the maintenance of his perfect efficiency both the military and monetary wealth of the community depend.

Secondly, that a paternal government must be always in a higher degree responsible for the lives of its subjects

Digitized by Google

than for the integrity of their goods, and therefore is bound to regard their health rather than their property.

Thirdly, because the employment of a medical adviser is a matter upon which the individual has no such option as is allowed him in the employment of other professional assistance, for—when sick—he is absolutely compelled to seek for medical aid which the State must, therefore, provide to the extent needful.

Lastly, because the selection of a medical adviser is a matter which cannot be safely left to the unguided discretion of his employer, and it therefore becomes necessary for the State to help in the exercise of a choice by guaranteeing the competency of the medical man.

As a very large employer of medical labour, the Government of our country is bound to ensure that it pays for none but the most highly qualified services, and, in the course which it has adopted with this object, it has recognised a marked distinction between the standard of competency which it considers necessary for its own uses, and that which it regards as sufficient for its subjects at large. In respect to the community at large the State accepts, as sufficient evidence of medical competency, the possession of a registrable diploma, but for admission to its own services it requires not only the guarantee of a strict competitive examination, but the probation of a further course of special education, subsequent to the study requisite for obtaining a diploma. The distinction thus drawn between the degree of skill necessary for the medical treatment of a soldier and that sufficient for a civilian might appear inconsistent with the relation of a paternal government towards its subjects, but, upon examination of the facts, that distinction will be found to be reasonable. In the first place, the skilled soldier or sailor is a very expensive article, not only in his maintenance but in his making, and for his medical protection, the Government is prepared to pay a higher price than the average subject could afford to give. Skill of a high order, obtained by a course of study of great extent and great expense, is necessary for the preservation of the health of the skilled soldier or sailor, and a special education of medical officers which is not needful to the civilian practitioner, is essential to the efficiency of our forces in time of war, and for these peculiar qualifications our Government is obliged to pay a higher price than the civilian need give.

While, however, it is the duty of a paternal government to put the choice of a medical adviser of guaranteed competency within the reach of its subjects, it is, in no sense, its function to relieve the community of the responsibility of selecting for themselves, according to their wants or their means, and, therefore, the State, in recognising licences to practice, contents itself with a *minimum* standard of medical education, confining itself to insisting that no one shall represent himself as competent to cure disease unless he be conversant with the principles and practice of medicine and surgery, and still leaving it to the individual who employs the practitioner to provide himself with an adviser of greater experience and higher attainments, if the gravity of the sickness or his own means of payment justify him in doing so.

The attitude of our own legislature in this matter is liable to be misunderstood, and those who look at the subject from a purely medical aspect are liable to demand the interference of the State for the purpose of maintaining an unduly high standard of medical education.

In our own country the freedom of the subject in respect to his selection of a medical adviser is recognised to the extent of tolerating the practice of medicine and surgery for gain by all sorts of persons—medical schismatics—prescribing druggists—incapable pretenders and even manifest swindlers; and it is an implied axiom of the law that no person shall be debarred from the real or pretended treatment of disease, or from taking fees for his services in this capacity so long as he does not deceive his customer by the pretence that he is a legally-qualified practitioner. It is strictly within the law (and moreover, within the limits of public toleration) that a person shall publicly set himself forth as competent and skilled to treat disease; that he shall recommend himself for employment by any statements true or false as he pleases, and that he shall obtain the money of his dupes by these means. If any one is ignorant enough or credulous enough to pay such a person for his services—so much the worse for the dupe. The law will not help him, except by a civil suit at his own risk in case he suffers damage by gross neglect or incompetency, and it will not undertake the punishment of the quack, unless he has falsely represented himself as being legally qualified, or has actually killed the patient by gross malpraxis.

With every regard for the liberty of the subject, and keeping out of view the interests of the medical profession, it seems to us very doubtful, whether the principle of freedom of practice is not pursued too far in our country. The same principle is not applied to other professions or even collateral to medicine. It is not permitted for an unqualified or unlicensed person to undertake the functions of a lawyer; nor is a litigant permitted to appear by such a deputy no matter how anxious he may be for such an advocate. In France there is a definite law on the subject, still in existence, of 19 Ventose year XI. of the Republic (March 10th, 1879), which is well known, and which relates to the practice of medicine, and regulates the prerogatives of physicians, licentiates, and of midwives.

The following are those portions of articles 35 and 36 of the law, to which we refer :—

Art. 35. Six months after the publication of the present law, any person who shall continue to practise medicine or surgery, or to act as accoucheur, without being on the list of those qualified to do so, will be liable to a fine, to be handed over to an almshouse.

Art. 36. Notice of such offence should be given to the tribunal of Correctional Police, and to the notice of the government commissioner (solicitor of the Republic to these tribunals). A fine of 1,000 fr. may be imposed on any person who shall take the title of doctor or practise as such.

A fine of 500 fr. may be imposed on any person who shall take the title of licentiate and visit the sick as such.

In case of relapse, the fine shall be doubled, and the delinquent shall be liable to an imprisoment, not exceeding six months.

The principal difficulty was, to know if the illegal practice of medicine could be punished by the penalties imposed by article 36 of the law, when there had been no usurpation of the titles of doctor or licentiate. This question has been decided. (Cour de Cassation, Novem-

Digitized by Google

ber 5th, 1831, and July 18th, 1840.) And it results from this decision of the Cour de Cassation, and from article 36 of the law, that the usurpation of the titles of doctor and licentiate are offences within the jurisdiction of the Correctional Police, and that the delinquents are liable to a fine of 1,000 fr. in the first case, and of 500 fr. in the second.

Even in Great Britain it is not allowed for any person unless duly licensed, as a pharmaceutist, to compound a medicine, although it is perfectly permissible for an unqualified person to prescribe the same medicine. In these instances the State forbids its subject to risk his life by employing a person incompetent for the service which is required of him, and it considers that perfect freedom of action in such matters is not tolerable with advantage to the community. It is not easy of comprehension why a different rule should be applied to the medical adviser, but the proofs are ready that the temper of the public and the legislature is against any prohibition of quackery. In the year 1878, a Medical Bill was introduced by Dr. Lush at the instance of the Medical Alliance Association, which directly prohibited medical practice by any but qualified practitioners, but such a storm was raised by the prescribing druggists that it had to be precipitately withdrawn. As lately as the 12th of March last, on the re-introduction of this Bill, without the prohibitory clause, Mr. Sergeant Simon and Mr. Burt, a working man's representative, delivered themselves of the following remarkable pronouncements :—

A few years ago a dead set was made by the profession against the homœopathists, and it was in consequence of that policy that a provision was introduced into the Medical Act of 1858 to protect them. If medical men did not now pursue the drugging system as before, it was because homœopathists had proved it to be injurious. If he chose to consult a herbalist or bonesetter, he did not see why Parliament should prevent him. (Hear.) A large number of friendly societies did not believe in medical men, but employed herbalists, who cured them, and they knew very well when they were cured. He had known friends of his own to go to herbalists, and persons of high position had made use of the services of bonesetters, and done so with advantage. His hon. friend's Bill said that none but a qualified practitioner should have the right to give a certificate of death. That was equivalent to saying that a man should not employ a herbalist, because if he died the herbalist could not give a certificate of death, and the man could not be buried. He begged to move that the Bill be read a second time that day six months.

Mr. Burt said he was acquainted with many herbalists who had done much service to the community. Within a few miles of Newcastle was one who had practised for 25 years, and to whom numbers of people came because they found themselves benefited. That man was typical of thousands, some of whom had never seen the inside of a college, and yet from some special aptitude they succeeded in curing diseases. When diseases were cured people did not care whether it was done by properly-qualified medical men or not.

It must be obvious, that the feeling of Parliament is hostile to any prohibition of unlicensed practice, and, therefore, it would be vain and foolish to offer any objection to the contemplated legislation on this point.

Notes on Current Topics.

Sickness of the Peshawur Valley Contingent.

The grave amount of responsibility devolving upon the War Office with regard to the selection of men, the absolute necessity for greater attention than has hitherto prevailed to the physical constitution of the soldiers sent on foreign service, and of the general inefficiency of young recruits under trying services of climate and long marches has been painfully exemplified on the return march of the Peshawur Valley Field Force. It is quite heart-rending to think of the sufferings that must have been endured by these men, exposed as they were to a temperature ranging from 110° to 115° in the shade. The troops were for the most part in a very indifferent state of health when they started. This arose from exposure, inactivity, and other causes. Nevertheless, a self-denying and excellent spirit is said to have animated them. But the excessive heat, dust-storms, indifferent food, intolerable thirst, scarcity of water, and that which was available being so bad as to cause diarrhœa or cholera, proved far too much for them.

On reaching Jam-rud and Hurri-Sing-ka-Boorj, and especially as they made their final marches, their distress was very apparent ; their clothes were stiff and dirty from the profuse perspiration and dust ; their countenances betokened great nervous exhaustion, combined with a wild expression difficult to describe ; the eyes sunken ; a burning skin, black with the effects of sun and dirt ; a dry tongue, a weak voice, and a thirst which no quantity of fluids seemed to relieve. Many of these men staggered rather than marched into their tents, and threw themselves down utterly incapable of further exertion until refreshed by sleep and food. Nor did the officers appear to be in any better plight.

But if there was one class worse than another it was certainly the medical officers and medical subordinates. Surgeon-Major Porter states that, on their arrival at Hurri-Sing-ka-Boorj, most of them were in a painfully helpless and prostrate condition, both mentally and bodily, This was attributable to the strain to which they had been subjected—almost incessant work, night and day, coupled with that anxiety and depression which even the most indifferent or callous must share in the presence of so much disease, fatigue, and responsibility. Some had almost literally no relief from toil, as, from so many of their number becoming ill, the duties were doubled and trebled for those who remained at their posts. The medical officer in charge of the section field hospital broke down early ; next the surgeon of the 4th Battalion Rifle Brigade ; and the third arrived at Hurri-Sing simply capable of handing over his sick before being himself placed on the sick list. The medical officers had been thrown entirely on their own resources in regard to the pitching and striking of tents, receiving no European assistance for this purpose.

Dr. Hanbury describes the condition of the medical officers, subordinates, and servants of the 1st battalion 17th Regiment, and section Field Hospital with it, on their arrival at Lundi-Kotal, as "a sad spectacle ; all were totally unfit for any duty. The medical officers complained sorely of the hard physical labour and great exposure to which they and the medical subordinates were subjected, in addition to their arduous professional duties, in awakening, arranging, starting, and driving the Kakars during their daily marches." "That all those," he continues, "in charge of the cholera hospitals did their work well may be inferred from the fact that the commanding and other officers repeatedly assured him the arrangements for their men were most satisfactory."

Digitized by Google

The deaths among the European corps in the 1st Division during the march comprised three combatant and three medical officers, all from cholera; 105 men from cholera, seven men from sunstroke, and nine from other diseases—a total of six officers and 121 men. There were also 11 deaths from cholera among the camp followers. The native corps lost one European and three native officers, 44 men, and 19 camp followers from cholera, one camp follower from sunstroke, 10 men and three camp followers from other diseases, or a total of 219 deaths in the division. This return is incomplete, as the figures have not been furnished by the I Battery, C Brigade, Royal Horse Artillery, E Battery, 3rd Brigade, Royal Artillery, and the Bengal Sappers and Miners; while those in respect of camp followers are from various causes inaccurate. From the second division we have only the daily cholera register, from the 6th of May to the 8th of June, which shows 48 cases and 35 deaths among European soldiers, 26 cases and 16 deaths among native soldiers, and 151 cases and 95 deaths among camp followers. There were therefore 236 deaths of fighting men, the great majority of them from either cholera or sunstroke.

On the Working of the Sale of Food and Drugs Act in England.

THE *Pharmaceutical Jour.* learns from the returns in the Report of the English Local Government Board just issued that the proportion of the samples analysed under the provisions of the Sale of Food and Drugs Act in the year 1878 reported to have been adulterated is lower by 2 per cent. than in the preceding year. The total number of samples reported upon was 16,191, and of these 2,782, or 19·2 per cent., were returned as adulterated. Too much importance, however, must not be attached to these figures, for irrespective of the fact that these percentages are based on the results of analyses as given in the quarterly reports of public analysts, and not upon the number of cases that have been tested in a law court, it needs only a glance at the abstract of returns to see that the figures may be affected seriously by local conditions and the number of samples examined, as well as the idiosyncrasy of the analyst. Thus in the column showing the percentage proportion of samples reported to be adulterated in the different counties we find Bucks returned as 0; Rutland, 0; Anglesey, 7·4; Bedford, 7·7; and Gloucester, 7·8; whilst Essex stands at 71·4 and Cumberland at 62·5 per cent It can hardly be contended that these figures represent correctly the relative proportions in which trading in adulterated articles exists in these counties.

The number of samples of "drugs" reported to have been examined is 491, of which 125, or 25·4 per cent., have been returned as adulterated. Here, again, there is a great diversity, Lancaster returning 22 adulterated out of 45, or nearly 50 per cent., whilst Lincoln reports none adulterated out of 25. The Board expresses regret that more samples of drugs are not submitted to analysis, "for it is obvious that prescriptions may have very different effects, according as they are made up with genuine or with adulterated medicines."

The Coroners Bill.

THE minutes of evidence as taken before the Committee of the House of Commons, with the *ad interim* report of said Committee thereon, are before us. The preliminary form of inquiry as adopted by the Procurator-Fiscal would, *prima facie*, appear to recommend itself, but in the case of an inquiry being fully carried out, it certainly was surrounded with a prolixity and abundance of red-tapeism that could not commend it to be adopted in any other country. The examination of the dead body by a special medical assessor to the coroner, the report of the former being forwarded with the police report to the coroner, would in many instances doubtlessly dispense with the summoning persons to hold a formal inquest. In Ireland, where the coroner happens to be a medical man, he might be permitted to hold a preliminary inquiry, and not a formal inquest, unless he found the circumstances of the case to be such as would require a jury to be empanelled. We collect from the fact of the Committee approving in part of the Scotch preliminary inquiry system, that they would also concur with this mode of dispensing with jurors. We are not surprised that the committee do not approve of the twofold form of inquiry, one before the magistrate, and the other before the coroner. Such has been already very forcibly condemned by the judges of the Irish bench as being very unfair to the accused, who, latterly, is not brought before the coroner as formerly, but behind whose back the investigation is held. As may or may not happen, he is either censured or found guilty of manslaughter or murder. To obviate such a proceeding as this the Committee consider it might be desirable that if a system of efficient salaried legal coroners were established throughout the country, there might be conferred on them the powers of a stipendary magistrate, and thus obviate the evils referred to. For the discharge of such duties we still assert that the medical coroner would be found as efficient and as competent as any stipendary magistrate, and we hope the Committee did not mean by such recommendation to exclude doctors as those eligible and specially fitted to hold the office of coroner. Both in England and in Ireland several doctors held, and still hold, the office, and in no instance has it ever been proven or insinuated that they lacked in any way the knowledge, legal or otherwise, to discharge the duties of coroner with satisfaction to themselves, and advantage to the public. We shall look forward with much interest to see a Bill passed into law next year that will redress the many grievances of which coroners have justly to complain.

The Metric System.

THE dream of an international language is not capable of realisation, though it is possible to introduce an international system of weights and measures, which will form a common language in the scientific world.

This is known as the metric system. It is easy of comprehension, and might usefully take the place in medicine of our present method of notation.

America has led the way in introducing the system into that great country, and Great Britain should not be behind hand, in giving a formal adhesion to the movement. The American Medical Association, somewhat analogous to the British Medical Association, has adopted it, and at the Cork meeting of the British Medical Association, Dr. Seguin advocated, and appealed to English practitioners on behalf of, this important alteration.

Dr. Seguin has sent us a long letter, from which we extract the following:—

Digitized by Google

If time was not raising an absolute impossibility I would like to read, and you would like to hear the opinions in favour of your adopting the metric system, sent to me by the Venerable Littré, representing Philosophical Medicine; Prof. Mehu, the celebrated Pharmacist; Drs. Auzoux and Lemercier, authors of the classic models of anatomy; Dr. Bertillion, the medical statistician; Marey, the inventor of many medical instruments of graphic observation; Broca, the organiser and secretary, I ought to say the soul of, the Society of Anthropology; L. Ranvier, the Professor of Histology at the College de France; Paul Bert, the Professor of Physiology at the Sorbonne. Professor Charcot, of world fame, the Professor of La Saltpêtrière, can tell you his disappointment at finding between his inquiring mind and the invaluable English medical literature, a mathematical barrier instead of a common pass-way.

But why should I longer try to convince you by foreign opinions, when the young teachers I have met with, as Sydney Ringer and Burdon-Sanderson, favour the introduction of the metric system in the school, the practice, the literature, the statistics of our profession?

Would you find these authorities too young? Then, permit me to quote the judicial—and I hope—final sentence of the most revered surgeon, Mr. Timothy Holmes.

"August 4th, 1879.

"18 Cumberland Place, Hyde Park, W.

"DEAR SIR,—I cannot help thinking that it is high time some uniform system of scientific notation were adopted; and as the metric system seems firmly established in the scientific world of the Continent, I believe that it would tend to the progress of medical science if we also adopt it."

But without this array of authorities, I cannot forget I address men of progress, ready to accept this, provided it could be accomplished by evolution, not by revolution.

That is why all that a foreign guest can do is to call your attention to the want of foreign physicians to read English authors in the common mathematical language of the sciences.

Anti-Vivisection Again.

THE institution of the "George Henry Lewes Studentship," has called forth from the "Society for the Total Abolition and Utter Suppression of Vivisection" one of the most curious advertisements that the world has lately seen. Bearing the name of the honorary secretary and treasurer, "George R. Jesse, Esq.," it sets forth in several paragraphs certain of the late George Henry Lewes' utterances before the Royal Commission. But the valuelessness of the opposition raised by the Anti-Vivisectionists was never more apparent than in this last attempt to influence the progress of physiological research. By simple quotation of scattered sentences, whose whole force can only be appreciated when their relation to their context is viewed, the excitation of a false sentiment in the ignorant and hyper-emotional, and the employment of highly-imaginative phrases and pictures—these are the fit and proper agents of a society such as that presided over by Mr. Jesse. Were it not as disheartening, it might be intensely amusing to see the ignorance displayed by these champions of sentiment. But since they do unquestionably exert a certian influence on the unreflecting women, it becomes a serious consideration how far this influence should be permitted to act unchecked. "In spite of all the baffled barbarity," Mr. Jesse's advertisement concludes, "a studentship for *both sexes* is founded for 'very powerful imaginations' to attempt to prove on complex organisms what cannot be proved." In thus presuming to dictate authoritatively on the possibilities of research, we venture to think the Anti-Vivisectionists assume a position calculated to do eminent mischief; and since their appeal is made to the ignorant and the prejudiced, who will think only in one direction, we conceive a vigorous protest should be entered against a practice which, though contemptible, can yet do much serious damage.

Suicide in Germany.

SUICIDE seems to be on the increase in Germany. From the statistics for the year 1878 we gather that the figure of 1,126 was reached, out of which 215 were women; in 749 cases death was produced by hanging, in 217 by drowning, and in 88 by injury to the brain.

The causes are thus assigned:—In 284 instances melancholia, in 105 disgust of life, in 94 intemperance, in 90 intellectual disturbance, in 89 privations, in 65 physical suffering, and in 39 love. The ages varied from 90 to 14 years.

According to the *Progrès Medical* of Sept. 20 we learn that in England during the last few weeks the number of suicides has been treble the number in the preceding period, and the writer makes the following sage observations, which English readers will take to heart:—"We suppose that the persistence of bad trade—the absence of the sun—the rain, storms, and inundations, have had some effect in exercising an unhappy influence on their temperaments."

We were under the impression that November was the usual or favourite month for Englishmen who were tired of life to throw themselves from the top of St. Paul's or the Monument—at least, we have heard that story when on the Continent. It seems that our suicides are forestalling their time, and September must in future be marked as a black letter month in the calender. We might ask whether some of our suicides may not be attributed to the very heavy literature of our scientific journals, and that the discussion of such questions as "Is life worth living for?" may have its answer in the negative.

The Thin End of the Wedge.

THERE is one parrot-like formula indulged in by some well-meaning teetotal advocates on which we shall say a few words, as, having the interests of temperance at heart, we believe that progress is impeded by this old formula—by this cackling over one egg, which is not a sound one. We have so often read it, in reports of boards of guardians, that the familiar words return to us almost without a reference. The earnest teetotaler, whenever a gallon of brandy is ordered, gets up, and moves—"That this poison should not be ordered, as drink is the cause of all the misery and all the suffering in the world, and all the pauperism, all the insanity, all the crimes that cause our gaols to be filled, spring from it—why, then, give this poison to paupers?" *ad libitum*. Generally there is a discussion, ending always in the ordering of the medicine. The teetotaler believes he has done his duty—that he has gained, perhaps, half a convert, and that by these discussions he is getting the "thin end of the wedge in." Fallacious hope! for, as a rule (such is human nature), the medical officer takes no notice of his teetotal opponent, and continues prescribing the potent medicine, named by Richardson *ex id genus*

Digitized by Google

omne—"poison." The medical officer does not notice this rhodomontade because he knows that pauperism is not due solely to drink—that at least 60 per cent. arises from other causes; because he further feels that his conscientious convictions compel him to regard alcohol as a medicine of indisputable efficacy, and that he cannot be guided by the advice of committeemen, who in the first place, know nothing of what they are talking about, and, in the second place, are prejudiced and beyond the reach of argument.

The thin end of the wedge cannot be introduced in this manner; medical officers of workhouses are open to conviction, but they must be convinced by statistics and facts, beyond dispute, and we have no doubt, when these are forthcoming, there will be a radical revolution in the use of alcohol in poorhouse dispensaries. It is annoying to workhouse medical officers to have this subject brought forward in this manner at board meetings, and as no good is done by the persistent opposition of earnest teetotalers, we would advise a change of flank and some other mode of action to secure the result so ardently desired by those who believe alcohol in any form to be a poison.

Centenary of the Birmingham General Hospital.

THIS large and popular Institution has just completed the hundredth year of its existence. In the course of this period the population of the town has increased from 70,000 to nearly 500,000, and the hospital, which was opened with only forty beds, now contains 250. From an address which has been issued, we learn that since the foundation of the charity over a million patients have received medical or surgical treatment by its honorary and resident staff. In 1779 the annual subscriptions were about £900, and the total income was under £1,000. In 1878 the annual subscriptions amounted to £5,400, and the total income from all sources—subscriptions, donations, endowments, legacies, and periodical collections, was £15,000; of which, excluding special contributions, the ordinary income may be reckoned at £9,000.

As a fitting commemoration of the centenary of such a useful and prosperous charity, it is proposed to found a suburban hospital for the treatment of chronic cases. "An extension of the hospital in this direction has long been desired by the medical staff and the administrative body, who are unanimous in their opinion that it should no longer be delayed; but they deem it to be clearly inadvisable to make further extensions upon the present site. The existing building is no more than sufficient for the reception of urgent and accident cases, and even these occasionally strain the resources of the charity to the utmost; yet beds which might otherwise be allotted to urgent cases are not infrequently occupied by patients whose ailments, being of a chronic nature, require long periods of detention in order to their effectual treatment. Year by year a considerable number of patients have been necessarily detained for periods extending over many months, and the beds thus occupied would have been available for four times the number of urgent and acute cases."

To give effect to this proposal, a *special appeal* to the governors and the public will be necessary in order to raise the funds required for the building. But, in the state of commercial depression which now exists, the committee do not intend to make an immediate appeal for donations. "Their purpose will be served by recording in a formal manner the centenary of the noble charity, the administration of which, on behalf of the governors it is their happiness to conduct; and by proposing to commemorate that event in a manner which they believe to be most in accordance with the necessities of the poor, and with the design and traditions of the hospital."

The New Histological Laboratory of the University of Dublin,

Now in course of erection, is situated at the east end of the College Park, adjacent to the medical school, and to the new anatomical museum. It will be a long building, facing north and south. It will consist, beside the basement, of two stories. On the first will be the laboratory, with rooms for the professor and for the attendant. The laboratory will be a long room, lit from the north by several large windows. There will be three rows of tables along the room, giving accommodation to seventy students, and allowing to each three feet of space. The students, when working, will face the light, an arrangement which is far preferable to that by which they have the light at the side. On the second story there will be the lecture theatre, which will seat upwards of a hundred students, and in which the lectures on physiology will be delivered. Adjacent to the theatre there will be a large room in which apparatus will be kept, and in which preparations can be made for lectures. In addition to the rooms described the building will contain lavatories and water-closets. This laboratory will supply a want greatly felt since the introduction of practical histology into the curriculum for the degree in medicine. Hitherto the demonstrations have been given in a small ill-lighted room, capable of accommodating at most twenty persons, and which was accessible to the students only during the short term that the demonstrations lasted. It is hoped that the new laboratory, which will be always open, except during the vacation, will be largely used, not merely by the students in attendance on the collegiate course, but by others for research and study in both normal and pathological histology.

The Practice of Dentistry under the Tomes-Lubbock Act.

WE extract the following passage from the letter of a "Manager," published in the last issue of the *Pharmaceutical Journal*:—

It is a well-known and indubitable fact that there are hundreds of chemists, their managers and assistants, who practise dentistry—that is, who extract, scale, stop, &c., —as ably as any professional dentist can do, who under the late state of the law could not be hindered or prevented from so practising; and I take it that the new Act has been passed to give such practitioners a legal status, and to prevent from so practising unqualified men —mere empirics and charlatans.

Another fact equally well known with the above, is that in country places throughout the length and breadth of the land, there are uneducated and vulgar men who take first to "cow-doctoring" and farriery, but who are equally

Digitized by Google

ready at any time to bleed a horse or cow, or to cut a whitlow or extract a tooth for a human patient; and these are the men, I apprehend, who were intended to be, and who will be, prevented by the new Registration Act from practising dentistry.

It would be interesting to hear from this exponent of dental law by what authority he erects a moral or professional distinction between "chemists, their managers and assistants" (who, he truly says, have been invested by Sir John Lubbock with a legal status), and the cow-doctors, whom he designates as "unqualified men—mere empirics and charlatans." What education in medicine, surgery, or dentistry does a chemist's manager or assistant possess superior to that which a farmer or cow-doctor may acquire by experience? To our mind the balance of surgical competency seems likely to incline to the side of the "mere empiric and charlatan,' who, at least, has got his experience by the practice of cow surgery. It certainly appears to us a somewhat audacious assumption that the chemist's assistant—and we know what the status of that gentleman is—is qualified to practise dentistry "as ably as any professional dentist can do."

Ovariotomy and Cold Affusions.

During the past ten months Dr. Thomas has performed ovariotomy 22 times, in the Woman's Hospital, New York. Out of the 22 cases, cold affusion by Nebbris' method, has been employed in nine, with the result of 21 recoveries, and one death.

The death occurred in a patient sent to the hospital in a most forlorn condition, three weeks after delivery. The operation was resorted to as her only chance, as she was rapidly sinking, and she died from exhaustion. In this case cold affusion was not used.

Virchow on Medical Education.

At the International Medical Congress held at Amsterdam, during September, 1879, the Berlin professor held a conference on medical education. Virchow suggests that the different branches of medical science shall be classed methodically, so that the student will pass successively from the accessory sciences to anatomy, physiology, psychology, up to pathology and clinical medicine. As regards books, he considers the student should have concise treatises, or exact *resumés* of each part of medical knowledge, so as to save precious time, so often lost in perusing long-winded monographs. Virchow's views are not very new on this subject.

St. Mary's Hospital Medical School.

The Introductory Lecture by St. George Mivart, F.R.S., lecturer on comparative anatomy, was attended by a very large number of past and present students and others. The address was a brilliant epitome of the speaker's views on the philosophy enunciated by Stuart Mill, Bain, Herbert Spencer, and other eminent thinkers. A vote of thanks proposed by Dr. Handfield Jones, F.R.S., and seconded by Haynes Walton, F.R.C.S., was heartily responded to. A larger number than usual of entries, both for the entrance scholarship and otherwise, has been recorded.

In the evening the annual dinner of past and present students, was held at the Inns of Court Hotel. There was a large gathering, Mr. Haynes Walton was in the chair. The toasts of the evening were interspersed with solos and part songs by Messrs. Mivart, Havell, Lane, and Vivian.

Surgeon-Major Reynolds.

Surgeon-Major Reynolds, one of the heroes of Rorke's Drift, arrived on Friday last from Zululand on board the troopship *Egypt*, in medical charge of 1,019 officers and men, amongst whom were 117 invalids. These speak in the most grateful terms of his kindness and attention during the voyage. A suggestion has been made that he shall be entertained by the profession in this country. The distinction earned by Dr. Reynolds for his art and for himself renders the recognition a suitable and a desirable one, and we hope to see it fully carried out.

A New School.

A new school in connection with medicine will be opened in London some time during next month. The necessity for this has been shown in the results of the examination conducted by the Sanitary Institute of Great Britain, and it has now been decided to create a "School of Hygiene," in which technical instruction shall be given in the subjects of sanitation and public health. Classes are to be formed for preventive medicine, in which lectures will be delivered by Dr. B. W. Richardson, F.R.S.; practical sanitary science, in two sections—(1) medical and chemical, to be conducted by Prof. Corfield; (2) engineering and construction, by Captain Douglas Galton; and jurisprudence and sanitary law, under the care of Mr. W. H. Michael, Q.C., F.C.S. Each session of the school will consist of twelve lectures, and these will be of a character to prepare the students for undergoing the examinations of the Sanitary Institute of Great Britain and other bodies. The lectures will be open to persons of either sex, and by adopting a low scale of fees all classes will be enabled to benefit by them. It is difficult to estimate the good that may follow from this step on the part of the Sanitary Institute, and we wish all success to the scheme.

Supposed Accommodative Value of Eserine.

Dr. W. Cheatham, according to the Louisville *Medical News*, states that in sulphate of eserine we have a safe remedy by which the wearing of glasses can be put off for several years. In presbyopia, he says, there is loss of distinct near vision, caused partly by weakness of the ciliary muscle. Eserine contracts this, and time assists in restoring accommodation. A solution of the strength of one grain to the ounce of water is made, and a drop of this put it each eye at bed time. But suppose—as is the fact—that the ciliary muscle has little or nothing to say to presbyopia. What then?

The Mortality of Dublin.

The deaths registered in the Dublin Registration District during the week ending 27th ult. represent an annual mortality of 23·5 in every 1,000 of the population.

In twenty large English towns the annual death-rate

Digitized by Google

last week averaged 18·8 per 1,000 persons living, inclusive of London, in which the rate was 17·2; in Glasgow the rate was 15.9; and in Edinburgh, 13·6.

The deaths amounted to 142.

The number of deaths from zymotic diseases is 32, being 10 under the average for the corresponding week of the last ten years, a result due to the low mortality from diarrhœa, to which disease only 5 deaths were ascribed against an average of 15. The deaths from other zymotic diseases include 9 from small-pox, 7 from fever (2 typhus, 4 typhoid, and 1 simple continued fever), 4 from scarlatina, 2 from whooping-cough, 1 each from measles, croup, &c.

The deaths from small-pox are 4 in excess of the number in the preceding week; all of them occurred on the south side of the city, 5 being chargeable to No. 4 District, which comprises nearly all that portion of the south city east of Carlisle Bridge; in this district also, 3 of the 4 deaths from scarlatina occurred. The latter disease has been rather prevalent in No. 4 District of late, 16 deaths having been registered during the last ten years, but until very recently this district has been comparatively free from small-pox.

Although the deaths from small-pox exceed those in the previous week, the number of new cases of the disease admitted into the Dublin hospitals has fallen from 42 to 28. Twelve patients were discharged during the week, 9 died, and 80 remained under treatment on Saturday last, being 7 over the number in hospital on Saturday, 20th ult.

Compared with the preceding week, there was a decline in the number of scarlatina cases admitted into the principal hospitals, and an increase in cases of typhoid fever and pneumonia, but the returns regarding these diseases do not call for special remark.

The deaths of 14 infants under twelve months old, and of 3 children, aged between 1 and 5 years, were referred to convulsions.

The average number of deaths from diseases of the respiratory organs registered in the 39th week of the last ten years was 15; the only disease in this group to which any deaths were ascribed last week is bronchitis, from which 18 deaths resulted.

Vacancies in the Professoriate of the Queen's Colleges, Ireland.

The Professorship of Chemistry in the Queen's College, Belfast, being about to become vacant by the resignation of Dr. Andrews, who is also Vice-President of the College, candidates for that office are directed to forward testimonials before the 18th October, 1879. The Professorship of Practical Medicine in the Queen's College, Galway, has also become vacant by the resignation of Dr. Colohan, who retires in consequence of increasing age and loss of sight, having occupied the chair for many years. Amongst the candidates for the vacant professorship is Dr. Rice, of Galway, an *alumnus* of the Galway College.

The Pathology of Rabies.

The latest contribution to our knowledge of this disorder is made in the *Veterinary Journal* for October. M. Galtier, having carried out a series of most elaborate experiments, draws this most important conclusion:—That the saliva of a mad dog, obtained from the living animal and kept in water, continues virulent for five, fourteen, and even twenty-four hours afterwards. This fact has consequences of which everybody should be aware. Thus it seems that the water of a vessel in which a dog may have dropped some of its saliva in attempting to drink should be considered virulent during at least twenty-four hours; and next, that, as the saliva of a mad dog which has succumbed to the malady, or has been killed, does not lose its properties through mere cooling of the body, it is important, in examining the cavities of the mouth and throat after death, to guard against the possible danger of inoculation. M. Galtier tested rabbits with regard to rabies, and found it transmissible to them from the dog; also the rabbits' rabies from them to animals of the same species. The chief symptoms are paralysis and convulsions. The animal may live from a few hours to four days after the disease has declared itself. It is notable that the period of incubation is much shorter in the rabbit than in other animals, and this makes the rabbit a more useful reagent for determining the virulence of a particular liquid. M. Galtier found salicylic acid, injected daily under the skin, powerless to prevent the development of the development of the disorder in rabbits.

Fever Statistics in London.

At the fortnightly meeting of managers of the Metropolitan Asylums District, held on Saturday last, it was stated that at Stockwell during the previous fortnight there were 54 fever patients admitted; 8 died, 33 discharged, and 156 remained. At Homerton, 53 were admitted, 9 died, 67 discharged, and 163 remained. At Homerton Small-pox Hospital, 44 fever patients had been transferred, where they still remained, making a total of 363 now under treatment, an increase of 39 as compared with the preceding fortnight. Of small-pox patients at Stockwell 8 were admitted, none died, 24 discharged, and 16 remained. At Fulham 8 were admitted, 1 died, 12 discharged, and 15 remained. At Deptford 16 were admitted (11 being convalescents from Homerton), none died, 8 discharged, and 9 remained. The total number remaining under treatment was, therefore, 40, as against 75 in the preceding fortnight, or a decrease of 35.

Preliminary Education of French Midwives.

A recent ministerial decree requires that aspirants for the title of pupil midwives of the first-class in Paris shall undergo a preliminary examination in—first, reading; second, orthography and dictation; third, elementary arithmetic, including the first four fundamental operations of arithmetic and arithmetical operations founded on them; fourth, the elements of the metric system of calculation. This decree came into operation on the 1st October.

The entry at the different schools has been very large this session. It is thought this is largely due to the depression existing in commerce and agriculture. A number of young men who, under ordinary circumstances, would have entered a trade, or gone to farming, seeing little prospect in these directions, have turned their attention to medicine.

There were thirteen cases of scarlatina in the fever

Digitized by Google

hospital of the Enniskillen workhouse, two of which have died.

THE Corporation of the City of London have voted £52 10s. in aid of the funds of the Royal Infirmary for Children and Women, Waterloo Bridge Road.

WE hear that it is intended to promote Deputy Surgeon-General Gilborne to the full rank of surgeon-general, on his vacating the office of principal medical officer to the Dublin district.

ON board the troop-ship *Egypt* from Zululand, which arrived at Portsmouth last week, in addition to Surgeon-Major Reynolds, were the following Army medical officers —Surgeon-Major A. C. R. Robertson, Surgeon-Major D. C. G. Bowins, and Civil-surgeons Beresford, Wardrop, and Reynolds.

LAST week the profession in Scotland was deprived of one of its most prominent and respected members by the death, from typhoid, of Dr. Fleming, the representative on the General Medical Council, of the Glasgow Faculty of Physicians and Surgeons. A short obituary will be found in our department for Scotland.

LAST week a new cottage hospital was opened at Bourton-on-the-water, by the rector of the parish. The building is from a design of Mr. Cutts, architect, of London, and the cost £1,100, towards which about £900 has been already subscribed. The day was observed as a holiday at Bourton, and amongst the speakers at the luncheon was Mr. Burdett, of the Greenwich Seamen's Hospital, who has done so much to further the extension of cottage hospitals throughout the Kingdom.

THE death-rate last week from the seven principal zymotic diseases averaged 3·8 per 1,000 in the large towns, and ranged from 1·2 and 2·5 in Norwich and Bristol, to 6·4 and 6·5 in Brighton and Salford. The deaths referred to diarrhœa showed a further decline. Scarlet fever was somewhat fatally prevalent in Sunderland, Nottingham, and Newcastle-on-Tyne; and measles in Liverpool. Diphtheria caused 2 deaths in Nottingham. Two fatal cases of small-pox occurred in London, 9 in Dublin, but not one in any of the other large towns.

COMPARED with the death-rates in the United Kingdom the following are the most recent weekly returns from the principal foreign cities :—Calcutta 27, Bombay 40, Madras 35; Paris 24; Geneva 19; Brussels 27; Amsterdam 22, Rotterdam 23; The Hague 22; Copenhagen 27; Stockholm 17; Christiania 11; St. Petersburgh 33; Berlin 28, Hamburg 29, Dresden 25, Breslau 31, Munich 35, Vienna 26, Buda-Pesth 32; Rome 29; Turin 24; Alexandria 45; New York 23; Brooklyn 21, Philadelphia 20, and Baltimore 20 per 1,000 of the population.

A notorious London quack, Martin Osterfield Ray, *alias* "Dr. Du Voy," of 36 Homer Street, Marylebone, was summoned last week by the Medical Defence Association, on the information of Mr. Reginald Wilson, student of St. Mary's Hospital, for falsely pretending to be, and prescribing as, a medical practitioner. Evidence was given to the effect that Mr. Wilson had one of the customary quack pamphlets placed in his hand in the streets. He communicated with the person named in it (Dr. Du Voy), explaining certain symptoms as to pains in the back, &c., from which he suffered, though, in fact, he had nothing the matter with him. He received a letter signed Dr. Voy, but did not take any notice of it. It contained a card bearing on it the name "Dr. Du Voy." He received two other letters, and then went to the defendant's house. The defendant said he had written to him, and then proceeded to speak about medicines that he ought to take. Mr. Wilson said he had not enough money with him and left.—In cross-examination, Mr. Wilson said as a medical student he was interested in putting down illegal practitioners.—For the defence, Mr. Berkeley said Du Voy was no myth. He was a medical practitioner in France, and the defendant was an assistant in London.—One of the defendant's men was called, and in answer to Mr. De Rutzen, said many people who came there, asked to see "the doctor."—The magistrate observed that this was exactly the case which the Act of Parliament was enacted to deal with, and imposed the full penalty of £20 and costs.

We congratulate the Medical Defence Association, and Mr. Wilson, upon the result of their joint action. The quacks have been getting rather the worst of it lately, and we think that were other gentlemen to come forward at a little personal inconvenience, as Mr. Wilson has done, these pests of Society would migrate to other "fields and pastures new."

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

HEALTH OF EDINBURGH.—For the week ending Saturday, the 27th ult., the deaths in Edinburgh amounted to 57, and the rate of mortality remains thus the same as in the previous week, viz., 14 per 1,000. The birth-rate continues unusually high.

GLASGOW MORTALITY RETURNS.—Dr. Russell, the city medical officer, has issued his report regarding the mortality for the quarter ending June last. The three months referred to had a lower temperature than any corresponding period for the past ten years, while the death-rate was also smaller. The average death-rate of Glasgow in the second quarter of the year for the past decade was 29·6, for the last quarter it was 23, and the birth-rate 39 per 1,000 living. During the quarter under review, Glasgow enjoyed an almost singular immunity from infectious diseases of children.

BANFF.—Dr. Manson and Dr. Hirschfield have been appointed physicians to the Banff Lunatic Asylum, the Lunacy Board resolving to make this arrangement, instead of electing a visiting-surgeon in succession to the late Dr. Clayton.

FORFAR.—THE INFIRMARY.—The annual meeting of the directors and the subscribers to the Forfar Infirmary, was held in the Town Hall on the 29th ult., ex-Bailie Reid in the chair. The eleventh annual report by the directors bore that the institution continued to be useful and make progress, but it was pointed out that only one of the public works in town had contributed during the year, although the workers in many instances were greatly benefited by the institution. The medical officers report that of the 90 patients treated 77 had been dismissed cured or relieved, 8 remained under treatment, and 5 died. There had been no epidemic in the town, which had been unusually healthy. The income for the year

Digitized by Google

amounted to £651 15s. 1½d., including £271 13s. 2d., as the balance from last year, and upwards of £160 of subscriptions. The expenses amounted to £508 8s. 11½d., leaving a balance of £115 6s. 6½d. in favour of the infirmary.

THE POISONED FAMILY AT AYR.—It is now the opinion of the medical men who have been inquiring into the cause of death of the children Macharg, who suddenly died at Ayr, as noticed in our last issue, that it is not to be traced to their having partaken of rotten herrings, but that it was due to suppressed scarlatina. The post-mortem examination did not reveal poisonous ingredients in the stomach, and while it is possible that their having partaken of the fish may have accelerated their disease, it must be referred directly to natural causes. The fifth child has also died.

THE HIGH DEATH-RATE OF PAISLEY.—Dr. Richmond, the medical officer to the local authority of Paisley, has just issued a report as to the high death-rate of the burgh, in relation to drainage, water supply, and nuisances. Dr. Richmond premises that some abatements should be made from the alleged high death-rate on account of the population having been under-estimated by the Registrar-General to the extent of probably six or seven thousand, while at the same time the increase in other towns has been overrated. A defective supply of water is not a cause of the high death-rate, as Paisley is abundantly supplied with the finest gravitation water. There is one specialty in regard to the employment of the inhabitants, that there is a great demand for female labour in the town. The excess of death-rate does not arise from infantile mortality, but is found in the grown-up population, and in the wage-receiving population (90 per cent. of the deaths during the past six months belonging to this class.) It consists in a large preponderance of zymotic, pulmonary, and tubercular diseases, and the deaths are spread very generally over the whole town, especially wherever there are an inferior class of tenants and tenements. These considerations, it is maintained, show conclusively that the exceptionally high death-rate is due to defective drainage and other insanitary conditions. The remedy suggested are the sanitary improvements of back courts, the adoption of the pan and dry closet systems, and a systematic house-to-house visitation.

CRYPTOGAMIC SOCIETY OF SCOTLAND.—Dr. Dickie, ex-professor of botany in the University of Aberdeen has been appointed Vice-president of the Cryptogamic Society of Scotland, while Professor Trail (Dr. Dickie's successor), and the Rev. Mr. Keith, Forres, are among the members of the Council.

DEATH OF DR. J. G. FLEMING.—Dr. J. G. Fleming died at his residence, Bath Street, Glasgow, on the 1st inst., from an attack of typhoid fever. Dr. Fleming was in the 70th year of his age. The deceased gentlemen was an ex-representative of the Faculty of Physicians in the General Medical Council, and for many years surgeon to the Royal Infirmary, of whose medical committee he was chairman. He took a great interest in the conduct of the institution, and was mainly instrumental in the institution of the regulations under which the medical and surgical appointments at the infirmary are now held. There can be no question that in this matter Dr. Fleming had the interests of the institution at heart, but these regulations, whereby the appointments are virtually life ones, are regarded by the profession with righteous disfavour. Dr. Fleming took a prominent part in the formation of the medical school and the Royal Infirmary. He was three times elected president of the Faculty of Physicians and Surgeons, occupying the office altogether for a period of eight years. Deceased was well-known in Glasgow, and enjoyed a considerable practice as a general practitioner.

OPENING OF THE NEW ROYAL INFIRMARY, EDINBURGH.—A joint meeting of managers of the Royal Infirmary, and a sub-Committee of the Lord Provost's Committee of Edinburgh Town Council was held in the City Chambers on the 1st inst., with reference to the arrangements proposed to be made for the opening of the new Infirmary buildings. It was decided that the ceremony shall take place on Wednesday, the 29th inst., and a remit was made to a small sub-committee of the two bodies to mature the arrangements, and report to another joint-meeting to be held on an early day. Disappointment was felt that the Duke of Edinburgh was unable to open the institution, and the duty of doing so has devolved on the Lord Provost.

BEQUESTS TO MEDICAL CHARITIES.—Mr. Alexander Turnbull Russell, of Easterton, Milnegaire, has bequeathed £1,000 to the Glasgow Royal Infirmary, and £500 to the Scottish National Institution for Imbecile Children.

Correspondence.

CALOMEL *v.* HYDRARGYRUM CUM CRETA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have been reading the communication of Mr. E. Marlett Boddy on the advantage of calomel as a remedy in some of the diseases of childhood. I write now a few lines to express my entire concurrence with the author in his disapproval of the well-known powder of mercury with chalk.

As a means by which the system may be gradually saturated with mercury, small doses of mercury and chalk powder are doubtless very effectual; but as a cholagogue to induce secretion from the duodenum and liver, I believe a far more certain medicine is found in calomel. One grain of calomel triturated for some time with twelve grains of sugar of milk forms a very active cholagogue powder, when administered in a dose of one or two grains.

The well-known blue pill also may be depended upon for cholagogue action, especially if the pill mass be of some age, so that a small quantity of the sub-oxide of mercury has been developed in it. Metallic mercury, "killed" by minute trituration with sugar of milk, forms a grey powder that can be easily prepared in the same way as the hydrargyrum cum creta, and, so far as my experience goes, is a preferable medicine. Hydrargyrum cum magnesiæ I have also tried in one case, but have nothing special to report of its action.

I give a decided preference to calomel and blue pill as the best forms for obtaining the cholagogue action of mercury.

The practice of frequently administering small doses of hydrargyrum cum creta, with a view to correcting secretions, is objectionable, as its tendency is gradually to impregnate the system with the mercury, and so produce irritability and anæmia.

I am, Sir, yours, &c.,
JOHN C. THOROWGOOD, M.D., F.R.C.P.

Welbeck Street, W.
Sept., 1879.

MEDICAL OFFICERS OF HEALTH.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—While the transformation of the sanitary officer of the Public Health Act, 1874, into that of the medical officer of health of the Public Health Amendment Act, 1878, is being effected, perhaps a few suggestions to the supposed transformees, and on the system in general, may not be out of place. It is not easy to discuss a question of such magnitude in its entirety within the understood limits of a letter, so I shall only refer to one or two points as concisely as possible.

The Local Government Board have decided that the duties of the Amended Act, 1878, are not to be superadded to those of the sanitary officer of 1874, but that the appointment is virtually *de novo*, the sanitary officer compulsorily succeeding to a change in title, extra duties, and responsibility, and, I presume, remuneration proportionate to the increase. The Act of 1874 had for its object the reform of existing evils; with this the Act of 1878 combines that of prevention also. From what I can see, the new medical officer of health (high sounding title) is, as far as remuneration is concerned, at the mercy of the board of guardians. Take, for instance, the proceedings of the Mountmellick and Baltinglass Board of Guardians of the 30th ult. and 9th inst. respectively, in both of which the Boards proposed to reduce, instead of increasing, the remuneration of the newly appointed officer of health, under the threadbare subterfuge of depression of trade and high rates. The remuneration attached to these offices under the old system in these unions was in some cases £15, in others £20, per annum. This precedent will, I venture to say, find a counterpart in every poor-law union in Ireland. In this union (Naas) the new officers have been appointed at the old rate of remuneration. The fact is this, we are proverbially a dirty nation; we have a time-honoured affection for our manure heaps and cesspools, consequently sanitary legislation, which would overthrow these institutions, is not popular. Witness the observations of an enlightened Poor-

Digitized by Google

law guardian of the Baltinglass Union (who I am certain is the proprietor of some cherished nuisance), under the gruesome stimulus of reform and increased taxation). "We don't want them (*i.e.*, the officers of health); they are not required; I don't see what good they have done." Chorus, "None whatever." These be thy gods, Oh Israel! To them must you look for appreciation of, and remuneration for, your efforts in saving them from themselves.

After all, it is no easy task to subvert institutions and reform abuses of some centuries' standing. The compulsory duties of a sanitary officer are not pleasant nor conducive to the popularity of a medical man. Why are such duties thrust upon him, and why is the remuneration so inadequate to the importance and extent of the work? I was sanitary officer once of a large and very filthy district in the West of Ireland. In the hovels the pig resided under the family bedstead, the hens roosted above it, and incubated in it. A calf or two shared with the occupants the body of the house, and the manure heap was kept indoors to "sayson it!" As a necessary result, the district was periodically decimated by typhus. These hovels were generally clustered together in villages for fear of the "fairies." Unity is strength. Fired with sanitary zeal, I attempted the purification of this Augean stable, with the following result: The occupants having been duly warned by the sub-sanitary officer, I proceeded to inspect, and to punish with the rigor of the law all non-conformists. But while I was yet afar off the inhabitants, who were previously apprised of the visitation, locked the doors and betook themselves helter-skelter to the mountains, leaving only in occupation old hags, who could find "no English" for the occasion, and children "with no language but a cry." They were beyond the reach of law and bad language, and I was made the subject of many jokes and much laughter, till overcome by the ludicrous, I lighted my pipe and laughed with them. My remuneration was £10 per annum.

Sanitary expenses are borne in part (half, I believe), by a Parliamentary grant from Government. This being the case, the acceptance of the post being compulsory, and the appointment subject to the approval of the Local Government Board, why do this body not interfere, and if not regulate, at least make, the remuneration fixed by the boards of guardians subject to their approval. If work is to be efficiently and conscientiously performed, it must be paid for, and the good effects of improved sanitary arrangements would be apparent in the decrease of pauper sickness, especially of an epidemic nature, and a commensurate diminution of union taxation.

I am, yours, &c.,

LESLIE MATURIN, L.R.C.S.I., L.K. & Q.C.P.I.

The Cottage, Blessington, 13th Sept., 1879.

A MODEL IRISH GUARDIAN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A friend of mine has handed me a copy of your issue of the 17th inst., in which appears an article entitled, "A Model Irish Guardian." As I am the guardian alluded to, I trust, in fairness, that you will afford me space in your columns for a short answer. I don't know whether you are a medical man, but from the *animus* of the article I suppose so, as the words used are a fair specimen of the education imparted in the profession, as many of its members indulge so when touched; but I don't see why human *leeches*, even doctors, are not to be restrained from overgorging themselves.

I suppose you have not a personal knowledge of Irish sanitary matters in general, so I attribute your calumny of the rank filthiness of the normal Irish cabin to ignorance, or perhaps the communication of some interested Irish correspondent, who fattens on misrepresenting his native land.

For a country so poor as Ireland to be burdened with enforced medical charities, and what is worse, that sham sinecure to officers, a Sanitary Act, and putting the expense of both on the poor-rate—many of our most enlightened guardians think mis-legislation—as the dispensaries in existence before the Medical Charities Act became law, were found to be quite ample, and the police at the present time could perform all sanitary duties better than they are done now.

With regard to your personal remarks about myself, I pass them all over without notice, merely stating that those who know me (and they are many) will not require my production of a certificate from the *Medical Press*, as to sanitary, or any other matter.

I am, yours, &c.,

OWEN JOSEPH CARAHER.

Cardistown, Ardee, September 29th.

[If our observations, to which this gentleman takes exception, needed any justification, this letter would afford abundance thereof. We—unfortunately—know all about the rank filthiness of the normal Irish cabin, with its hens and jackass in the bed-chamber, its manure bog on the doorstep, and its supply of drinking water from the nearest ditch. But for Mr. Caraher all this is as it should be; and an "enforced Medical Charities and Sanitary Act," are a useless invention of the "the Saxon." If it be true that the "most enlightened guardians" of the Ardee Union consider the old dispensaries of an almost pre-historic age are "quite ample," all we can say is we are glad we are not born to the lot of an Ardee pauper. In our opinion any one who could possibly hold to such an idea is ridiculously unfit to be a guardian, and knows as little of sanitation and cleanliness as—well! as Mr. Caraher does of manners.—ED. M. P. & C.]

ON DAVOS AS A HEALTH RESORT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read in a pamphlet by Dr. Ramage "that Lænnec laboured under a great mistake in supposing that the lungs, having once a tuberculous deposit, were inevitably liable to an invasion of new tubercles, and that owing to enlargement of the tonsils, asthma, disease of the heart, the habit is soon entirely altered; that scrofula in many instances ceases to exist, and also the formation of tubercles." If dogmatic opinion, egotism, and assertions called facts, could establish the curability of consumption in almost all its stages, I may safely say this has been done; and for the small price of one shilling the simple measures necessary to attain this object may be learnt. Why recommend change of air? It is absolutely unnecessary in the face of the aristocratic evidence we can adduce from this book. Our English climate, and the measures recommended by an author who has had experience of thirty thousand cases, are quite sufficient. But yet the profession were incredulous, not that they were unwilling to hear such glad tidings, not but that they would have welcomed with the most passionate ardour the discovery of the secret of consumption and its cure. But, unfortunately, the remedy proposed was not so successful in the hands of other earnest and anxious physicians, for that secret was, "You must come and consult me." When William III. was king one of the physicians who was in attendance thus impressed his royal patient: "May it please your Majesty," said Dr. Ratcliffe, "I must be plain with you, Sir. Your case is one of danger, no doubt; but if you will adhere to my prescriptions, I will engage to do you good. The rheum is dripping on your lungs, and will be of fatal consequence to you unless it be otherwise diverted." An English physician, who has fairly earned for himself a high position in medicine, has lately introduced to English readers another health resort—for phthisical patients. I earnestly hope that the *El dorado* is found, but I fear I shall be doomed to disappointment. How heartily I re-echo part of the introductory remarks on this new haven of health. I have "a desire almost passionate" to read the terrible secret of consumption—a malady which strikes the fairest and most precious lives, and but rarely strikes in vain.

Dr. Allbutt then adds: "Happily, it is as true of phthisis as it is of most other maladies, that modern medicine has thrown a flood of light upon its modes and causes, and thus contributed to a revelation of knowledge, only equalled in kind by the splendid energy of Greek civilisation, 600 B.C., and never equalled in degree and rapidity of achievement in the history of the world."

Knowing the integrity and the character of the writer, and his reputation as an observer, I looked forward not necessarily

Digitized by Google

to something new, but to a logical demonstration of what had been done, and to a practical exposition of a sound pathology and treatment; but I certainly felt doubts rising in my mind, owing to the evident personal equation of the writer in favour of Davos. When I analyse the sentenee about the flood of light thrown on phthisis by modern medicine, it resolves itself into very small practical results. Hundreds and hundreds of volumes have certainly been written upon this disease, and yet we have really made little advance since the great discovery of Lænnec. We are told that consumption "but rarely strikes in vain;" and Dr. Allbutt, in place of advancing into newer light, throws us back fifty years into the theories of Broussais.

Dr. Andrew Clark is said to have surprised many at the Manchester meeting of the British Medical Association by giving old wine in old bottles; but these crude thoughts and suggestions of Dr. Allbutt are very old indeed; for just before introducing the subject of Davos, and after an opinion that the fundamental treatment of phthisis must be anti-septic or aseptic, I find the following sentence:—

"The next hope seems to lie in some inhalation plan, or in some filtering of the respired air; but here one meets with much disappointment. It may be that inhalations do not reach the part, or that their action should be quite continuous."

This is very old wine. Forty-seven years ago, in a review on the successful inhalation of diluted chlorine in the early stages of pulmonary consumption, I find it written in the *Medico-Chirurgical Review*—"The sanguine expectations which were elicited by the theories of Lavoisier, and the ardent imaginations of Beddoes, and others respecting the efficacy of gases inhaled for the cure of breaches of structure in the lungs have long been dissipated, before the clearer lights which have been shed on pulmonary consumption by pathological anatomy. Oxygen gas was to have done as much in former times as Saint John Long's liniment and insufflations are now said to do."

We know now the fate of St. John Long, and the result to his patients. But to return. "Notwithstanding the failure of inhaling oxygen and other gases—the fumes of tar and other medicinal substances—there is still a fond hankering after the direct application of remedies to the ulcerated cavities of the lungs." So that, with all our energy, with all the resources of modern medicine, we are still hankering after the old method which was thus mentioned in 1830.

The theoretical views, and the tendency to a pure faith in anti-septicism, which is still only a matter of opinion, militate against my accepting, with the implicit confidence I might otherwise have done, the narration of Dr. Allbutt, on the advantages of Davos as a health resort. We must, of course, modify the opinion of Lænnec in the face of the well-established facts we have. Much may be done in the early stages of consumption, both by medicine and change of air; whilst the post-mortem room has afforded us ample evidence that Nature herself has cured, without our suspecting the existence of a cavity in the lung; and this certainly offers us a reasonable hope that we may be able to imitate Nature's process.

In the selection of a climate for the invalid and for the phthisical, much care must be exercised; and it is one of the most difficult tasks which can fall to the lot of a general practitioner—to decide, from the many places recommended, where his patient should go. He must consider individual idiosyncrasy and organisation; for whilst the climate of Australia will prolong the life of one, it may only hasten the termination of the disease in another; and the same is true of the other favourite health resorts, familiar to all my readers. There are waves of fashion that periodically flow over the medical world—at one time, as a wave in favour of some new remedy; at another time, in favour of a new watering place, or continental sanatorium; and these waves ebb and flow not with the mathematical precision worthy of our profession, but seemingly dependent on circumstances of caprice and individual direction. This irregularity does not reflect much credit upon medicine, and I naturally then look with suspicion upon an addition to our health resorts, especially as in this individual case I am not satisfied with the weight of evidence in its favour.

Though I am not convinced yet, I must nevertheless thank Dr. Allbutt for submitting it to the notice of the profession, and thereby to the healthy criticism it ought to receive, which, far from doing it harm, will, if it is based on truth, only confirm its status. But as I have so often before eaten of Dead Sea apples, and had my hopes deceived, I am inclined to doubt.

The "Pilgrim in Pursuit of Health," when he painted the Bay of Naples, pictured the ideal climate we are seeking for, but which, I fear, only exists in the fervid imagination of the poet—

. . . . Here, if thou lovest a clime
Where health my flourish—rankling care decrease,
And beauteous Nature smooth thy stream of time.
Here . . . . .
Repose, and feast thy soul with scene sublime,
. . . . . .
The sunbeam shall not smite thee, for the sea
Tempers its fervour; winter's kindly ray
Shall never chill thee, for the myrtle tree,
Pomegranate, palm, and citron shade the bay
With fruit and foliage; Nature's face shall be
Thy book and mirror; one long summer day
Thy life; and when at last thou tak'st thy rest,
Unfading spring shall fold thee in her breast.

I am,
Yours faithfully,
London, Sept., 1879. INQUIRER.

Literature.

FOTHERGILL ON THE HEART AND ITS DISEASES. (a)

DR. FOTHERGILL is evidently not one of those physicians who, as far as regards the instruction of the profession, and the advancement of medical science, allow their knowledge and experience to run to waste. It too often happens that a small circle of patients are the only individuals to profit by the abilities and experience of their medical attendant, consequently when he dies the results of his matured judgment, and the stores of information he collected during perhaps a long life, perish and die with him. Neither his professional brethren nor posterity are one bit the wiser for what he said, or for what he thought.

A very different character is Dr. Fothergill. Although only a young man, he has already shown himself to be an industrious labourer in the field of clinical medicine, and to be as anxious to teach as he is to learn. Already we have had from his pen a popular treatise on "The Maintenance of Health," a very useful and practical work entitled, "The Practitioner's Handbook of Treatment," an original monograph on "The Antagonism of Therapeutic Agents," and now we have a portly volume on "The Heart and its Diseases," which, although a second edition of a treatise published in 1872, is so much enlarged and improved as to be virtually a new work.

Speaking in general terms of the book, it is the best as well as the most recent work on the subject in the English language, one in which both the student and the practitioner will find a safe and valuable guide to a knowledge of cardiac pathology, diagnosis, and therapeutics. There are several features which distinguish it from other works on the same subject. The author has not devoted too much space to a lengthy description of the physical signs of heart disease, a course which is more calculated to confuse than enlighten the mind of the reader. He also describes each form of disease, not merely as an assemblage of signs and symptoms, but as possessing a natural history, in the belief that such plan will interest practitioner and student alike in the genesis and progress of diseases of the heart.

In the next place, the author has laid under contribution the most recent additions which foreign authorities, especially German writers, have made to our knowledge of cardiac pathology. Hence the writings of Dr. Th. von Dush, Rindfleisch, and others on heart disease in general; the views of Claude Bernard, Cyon, Henry von Bezold, on cardiac innervation; and those of Ludwig and Traube on the connection between Bright's disease and heart disease, all receive due consideration. The reader will also find a good description of the evolution of the heart; whilst Dr. Balthazar Foster has contributed a very instructive section on the use of the sphygmograph.

(a) "The Heart and its Diseases." By J. Milner Fothergill, M.D. 2nd Edition. London: H. K. Lewis.

Digitized by Google

Another excellent feature of the work is a long chapter on "The Gouty Heart," a subject to the consideration of which the author has devoted as many as seventy pages. Lastly, the subject of "treatment," which is in many medical works dismissed with a few curt, somewhat desponding remarks, monopolises a large share of the author's attention. In fact, therapeutics is one of his strong points, and the chapter on the "Treatment of Organic Disease of the Heart," as well as the other therapeutical part of the work, will be perused with great satisfaction.

In passing now to the consideration of the manner in which the author has handled certain portions of his subject, we shall begin by noticing his account of the innervation of the heart, a question which is particularly interesting to those who would form some conception of the pathology of certain affections of this organ, as well as of the *modus operandi* of certain drugs which have been found by experience to have a marked influence on its action, both in health and in disease. The statements of physiologists with regard to this subject must be received with some reservation, as the cardiac branches of the spinal and sympathetic nerves are so intimately connected one with another, that it is difficult for the experimenter to differentiate the respective parts which those nerves take in the regulation of the heart's action. Recent researches show that the conclusions drawn by one observer are not infrequently shown to be incorrect by another, and we are by no means sure that the prevailing opinion on the subject will not have to be modified by future investigations. We are, however, pretty certain that the action of the vagus nerve on the heart is chiefly of an inhibitory nature, that is to say, it slows its action, and calms it when over-excited. This nerve is also, as Dr. Fothergill well puts it, "a rope of many strands." It appears to contain (1) direct or efferent inhibitory fibres; (2) reflex inhibitory fibres; (3) afferent fibres to the vasomotor centre—the sensory nerve of the heart of Ludwig. The first mentioned fibres directly control the heart's action, and by their restraining action hold back the explosion generated in the ganglia until a synchronous contraction is secured. Hence, when the vagi are cut, the contractions are tumultuous. It is also owing to the action of those fibres that some people are able to exercise a decided control over their heart by an effort of the will. The reflex inhibitory centres are those by which the heart is brought to a standstill in diastole, as when death follows a severe blow on the pit of the stomach, and through which fainting from severe emotion injury, &c., is brought about; while the third strand consist of vaso-inhibitory nerves running from the heart to the medulla, and which, thrown into action when the heart is unduly distended, inhibit the vaso-motor centre, so that the *peripheral arterioles* are dilated, and the blood pressure in the arteries lowered. But here we must remark that the author does not quite succeed in making clear the practical bearings of the heart's innervation. Nor is it easy to do so, considering that the function of the cardiac nerves, especially of the accelerator fibres, is far from having been exactly made out.

Turning to more practical matters we notice that the author has given an excellent and philosophic description of hypertrophy and dilatation of the heart. In speaking, however, of the causes of this disease, he particularly refers to one which he says has been little attended to, except by Dr. Wardrop, namely, that arising from violent sustained efforts checking the bloodflow in the arteries, a cause which not only gives rise to hypertrophy of the left ventricle, but also to *aortic valvulitis*. But the influence of sustained muscular exertion in impeding the onward current of the blood, and thereby causing hypertrophy of the heart, has long been recognised. Dr. Quain called attention to the fact in his "Lumleian Lectures," where he confirmed the statements made by other writers before him, that hypertrophy of the heart might arise independently of valvular disease, as, for instance, from athletic sports carried to excess, from the wear and tear arising from the excitement of business, or from emotion of the mind. Perhaps our present habit of using such terms as "arterioles," "increased blood pressure," &c., sometimes gives an air of original novelty and precision to our present knowledge, to which it can lay no claim. With regard to the histological changes in large hearts, it is now known, as Dr. Fothergill shows, that there may be a false hypertrophy owing to increased growth of connective tissue, and causing very great enlargement of the heart. Also that true hypertrophy is considered by Rindfleisch and other recent pathologists to be owing to a true hyperplasia, or a development of nerve muscular fibres. But did not Dr. Walshe as far back as 1862 adopt a similar opinion?

This, however, is not the only instance in which our author has been, as he confesses in his preface, forgetful of the scientific claims of his own countrymen. The two important questions, "Hypertrophy ever Destructive," and the "Question of Permanency (or Prognosis)," are well analysed in this chapter. When the obstruction lies in arteriole contraction, preventing the blood running out of the arteries, then the ventricular hypertrophy keeps up the high blood-pressure, within the arteries, and this over-distension leads to atheromatous change in time. Also in aortic regurgitation the hypertrophy . . . . is reunion to the arteries. The enormous ventricle at early systole draws with immense force an abnormally large mass of blood into the arteries, which are over-distended thereby.

On the whole, the author's description of this part of his subject is highly satisfactory; the only thing we miss in it is some account of the connection of hypertrophy of the heart with apoplexy and pulmonary hæmorrhage, which, although incidentally noticed in a previous chapter under the heading "The Consequences of Obstructed Circulation," and (as regards apoplexy) in a subsequent portion of . . . . is scarcely alluded to in the very place where the reader would naturally look for an account of these important complications. There is no chapter in this work which the practical reader will peruse with more satisfaction than that on "The Gouty Heart." Saving a little too much repetition and occasional digression, it is an admirable chapter, and takes up no fewer than seventy pages of this work. It is curious to observe that the association of changes in the heart and arterial system with changes in the structure of the kidney, was recognised as far back as 1817, when James, of Exeter, drew attention to it. His view, observes Dr. Fothergill, was that subsequently announced by Bright, viz., "that the altered quality of the blood might so affect the minute and capillary circulation as to render greater action necessary to force the blood through the distant subdivisions of the vascular system."

TESTIMONIAL TO W. P. O'BRIEN, ESQ. (LATE INSPECTOR IRISH L. G. B.)

On the 29th ult. there was presented to W. P. O'Brien, Esq., by the medical officers of the districts of which he had charge, on the occasion of his promotion to a Commissionership in the Prisons Board Department, a magnificently illuminated address, as well as a very beautifully ebonised inlaid drawing-room cabinet of most exquisite design. The deputation from the medical officers who presented the above were entertained at a sumptuous *dejeuner* at Mr. O'Brien's residence, at 42 Waterloo. The address and reply appear in another portion of our columns.

Obituary.

HENRY MAUNSELL, M.D., F.R.C.S.I.

The death of Henry Maunsell, the chief editor and proprietor of the *Dublin Evening Mail*, and one of the founders of the *Dublin Medical Press*, deserves from us a prominent notice, as his high qualities both as a literary and professional man call for the expression of a profound regret that he has gone from amongst us. He is stated to have been born in Dublin in 1806. He took in 1831 his first professional degree as M.D. of the Glasgow University, and in 1832 he became a Fellow of the Irish College of Surgeons. Obstetricity was in specialty, and in his early life he identified himself with that department by his publication of "The Dublin Practice of Midwifery," which for many years held its supremacy as the manual for the Dublin student. In recognition of his attainments in this direction he was shortly afterwards made Professor of Midwifery in the School of his College—in which institution he afterwards held the first chair of Hygiene, and acted for many years as the most energetic and useful Secretary of Council which it ever

Digitized by Google

had. His other professional book-work was his share in the production of "Maunsell and Evanson's Diseases of Children," which he issued in partnership with Dr. Evanson, who died some two years ago in practice at Torquay; but he left his mark upon the pages of the *Medical Press* and other journals in the form of numerous and valuable articles on Hygiene and on various professional subjects. In 1839, Henry Maunsell, having associated intimately with the late Dr. Arthur Jacob in the agitation for reform of the construction of the Irish College of Surgeons—which agitation bore fruit in the new charter granted to that body in 1844, as well as in the abrogation of the apprenticeship system and the establishment of the Irish Medical Association—undertook in partnership with Jacob the establishment of the *Dublin Medical Press*. His services to the journal were great and lasting for—while the general direction of its policy and most of the editorial work was done by Jacob—the junior partner threw himself with such enthusiasm into its business management, and did so much to achieve its character for spirited management that his labours speedily established it in a condition of safety and permanent success. But Maunsell did not long confine himself to the literary work of his own profession. He was a constant contributor to the *Dublin University Magazine*, and, in 1846, distinguished himself by a *brochure* on a federal Parliament, thus having laid the foundation of the now powerful agitation for "Home Rule." In the year 1858 he bought from Mr. Sheehan the *Dublin Evening Mail*, for which he continued constantly to act as editor, in conjunction with a gentleman well-known and esteemed. As a public man Dr. Maunsell occupied a prominent niche. As a leader-writer he was characteristic, forcible, and scholarly, as a friend or acquaintance he was at once racy and genial. His memory will long survive.

NOTICES TO CORRESPONDENTS.

RURAL SANITARY OFFICER asks—1. How is a medical officer of health to decide whether meat is unsound or not in the incipient stage of decomposition? 2. Are there any tests besides those of smell and observation? 3. If the medical officer seizes diseased meat, and the justice before whom said diseased meat is brought refuses to condemn it, how in that case is the medical officer to act? Has the trader or seller an action against him?

[1. The peculiar cadaverous odour, the preternaturally dark colour, the damp condition of the serous membranes, the moist soft state of the fat betray unsound meat. 2. The above tests are sufficient. 3. The medical officer is liable to an action under any circumstances, for it is almost impossible to prevent persons from bringing actions, even without the slightest grounds for such proceedure. If it is shown that the medical officer acted in *bonâ fides*, and had reasonable grounds for suspecting that the meat was diseased, the judge would probably not allow the case to go to the jury; under any circumstances no damages would be awarded.—ED.]

M. CASEY.—The regulations of the Queen's University in Ireland have always been given at full length in our Student's Number, but were omitted this year because—as stated—the University has ceased to exist, and its regulations are therefore effete.

DR. K.—Guardians have not usually distinguished themselves for consideration towards poor-law medical officers. We hope they may do so in your case.

MR. J. E. R.—A quack with a legal qualification.

M.D., Scarborough.—We expressed our opinion of the learned professor when he was lecturing at Chester in a leading article some few months since. He is, as you opine, not a bad judge of human nature; hence, he fattens upon the credulity of the masses.

DR. J. W. L.—It has always been considered derogatory to the dignity of the profession to retain secret remedies when the discoverer has proved them to be of service to mankind. The usual plan is to make such discovery known in the medical journals, or in book-form. It is undoubtedly true, as you observe, that "the public are not grateful for that which costs them nothing." And as you consider the specific of pecuniary value, your only means of introducing it to the public is through the agency of one of the best drug houses.

THE ELECTRICAL TREATMENT OF PARALYSIS, EPILEPSY, &C.—We are asked to state that the Committee of Management of the West End Hospital for Diseases of the Nervous System, 73 Welbeck Street, London, W., have ordered that those medical men who prescribe electricity for their private patients, but have not time or proper appliances, may have the treatment carried out in the Electrical Room of the Hospital. This rule is applicable solely to those who produce a letter from a registered medical practitioner, addressed to the Medical Superintendent.

CLINICAL SOCIETY OF LONDON.—On Friday evening next, at 8 o'clock, Report of the Committee on Dr. Douglas Powell's case of "Leprosy with Enlarged Glands."—Dr. Dyce Duckworth, a "Case of Myxœdema."—Dr. Ord, "Notes from Cases of Myxœdema."—Dr. F. Taylor and Mr. Howse, a "Case of Empyema in which portions of Ribs were Excised."

A MEDICAL MEDLEY.

THE following parody on Bishop's well-known glee, "O who will o'er the Downs," was sung at the dinner of the Bradford Medico-Chirurgical Society last week:—

O who will o'er the roads so rough?
O who will with me drive?
O who will come, and fast enough
To keep a wife alive?
The husband he has come from far,
The mother longs for me;
But husband's love nor mother's care
Suffice to set her free.

I saw her in the morning grey;
She bade me come again,
But at the eve of yesterday
I left her free from pain.
The nurse and friends had gone to sleep,
And none were there to see
The true wife wake, and walk, and weep,
Nor bring her wails to me.

I promised her to come again
Whene'er for me she'd send;
Nor darkness, thunder, nor the rain
Should keep away her friend:
I promised her to come at night,
Nor made her wait for me;
And e'er the dawn of morning light
I set my lady free.

VACANCIES.

Dore Union, Hereford.—Medical Officer for the Workhouse and District. Salary, £80, with an additional allowance for the duties of Health Officer. Applications to the Clerk at the Union Offices before Oct. 20.

Oakham Union.—Medical Officer for Workhouse and District. Salary, £70, with usual extra fees. Applications to the Clerk before Oct. 14.

Queen's College, Belfast.—Professorship of Chemistry. Applications to the Under Secretary, Dublin Castle, before Oct. 18.

West Sussex Infirmary.—House Surgeon. Salary, £80, with board, and £20 extra for duties as Secretary. Applications to the Secretary at the Infirmary, Chichester, before Oct. 25.

APPOINTMENTS.

BANKS, S. F., Secretary to the Royal Hospital, Belfast.

COUTTS, G., M.B., C.M., House Surgeon to the Teignmouth, Dawlish, and Newton Infirmary.

DENHAM, T. R., M.D., C.M., Medical Officer of Health for the Wigton Urban Sanitary District, Cumberland.

EDMUNDS, W., M.A., M.D. Cantab., F.R.C.S.Eng., Assistant Physician to the West End Hospital for Diseases of the Nervous System, vice Dr. Heron elected Physician.

GEOGHEGAN, E. G., M.D., L.R.C.S.Ed., Assistant Medical Officer to the Gloucestershire Lunatic Asylum.

LUMSDEN, G., M.B., C.M., Medical Officer for the Northern and Central Districts and the Workhouse of the Pately Bridge Union, Yorkshire.

MACKENZIE, Dr. J., Physician to the Hospital for Diseases of the Throat and Chest, Golden Square.

O'CONNOR, L., L.K.Q.C.P.I. & L.M., L.R.C.S.I., Certifying Factory Surgeon for the District of Glenarm, co. Antrim.

WATSON, J. B., L.F.P.S.G., Medical Officer for the Bourn District and the Workhouse of the Bourn Union.

WILSON, Mr. A. S., Professor of Botany at Anderson's College, Glasgow

Births.

HAMILTON.—On Sept. 27, at Tandragee, co. Armagh, the wife of Thos. K. Hamilton, M.B., of a daughter.

O'SULLIVAN.—On Sept. 27, at 6 Camden Place, Cork, the wife of Stephen O'Sullivan, M.D., of a daughter.

ROGERS.—On Sept 27, at 4 Oxford Road, Rathmines, the wife of G. P. Rogers, L.R.C.S.I., of a son.

ROOME.—On Sept. 28, at North Esk, co. Cork, the wife of H. Roome, M.D., of a son.

Deaths.

CAMERON.—On Sept. 12, at Port Ellen, Islay, John Cameron, M.D., aged 42.

DAVIES.—On Sept. 10, at Kilmore, co. Wexford, George Davies, M.D.

EVERET.—On Sept. 27, at the Barracks, Chichester, after a few hours illness, Surgeon-Major Wilton Everet, Army Medical Department, aged 48.

FLEMING.—On Oct. 2, at his residence, Bath Street, Glasgow, J. Gibson Fleming, M.D., in his 70th year.

HARRIS.—On Sept. 22, at his residence, Lake Street, Leighton, George S. D. Harris, L.R.C.P., M.R.C.S.E.

LANG.—On Sept. 26, at Berners Street, London, Henry Lang, M.B., aged 59.

MACCARTHY.—On Sept. 9, at Cottage Grove, Southsea, Thos. MacCarthy, Staff-Surgeon R.N., retired.

MALCOLM.—On Sept. 15, at South Street, St. Andrews, Fifeshire, Thos. Malcolm, L.R.C.S.Ed.

MAUNSELL.—On Sept. 27, at Greystones, co. Wicklow, Henry Maunsell, M.D., aged 73.

MOON.—On Oct. 2, at St. Leonard's-on-Sea, Hy. Moon, M.D., F.R.C.P., of Brighton, aged 68.

IRISH POOR-LAW INTELLIGENCE.

LIABILITY OF DISPENSARY COMMITTEES FOR EXPENSES OF CANDIDATES.

THE proceedings of the Committee who have charge of the Clonegal and Coolattin Dispensary District in the co. Wicklow, raise the question as to how far committeemen can be made liable for the expense and annoyance incurred by gentlemen who attend, at their order, for the purpose of an election which turns out abortive. In consequence of the resignation of Dr. Bookey, the committee announced that they would, on a certain date, proceed to elect a medical officer, no reservation whatever being made as to an adjournment. The advertisement, which lies before us, states that the personal attendance of candidates is indispensable. In accordance with this notification, and in certain expectation that the election would take place on the day named, two candidates presented themselves—one from Dublin, the other from a distant rural district. Their qualifications were strictly regular, and one of them had held office in the Poor-law service for fourteen years. On arrival at the scene of action a rumour reached them that it had already been arranged that the dispensary should be given to a young gentleman of personal influence in the neghbourhood, but that, as he did not yet possess the requisite diplomas, the election would be held over to await his securing the requisite qualifications. Nevertheless, the two gentlemen appeared before the committee, and were examined, cross-examined, and inspected, and finally told that the committee could not make up their minds for a fortnight, though, at the same time, it was inferred that the members were fully satisfied with the candidates who presented themselves. These candidates remonstrated warmly against the injustice of bringing them so far on a vain errand, and they stated that they would certainly expect that they should be recouped for their loss of time and their outlay. The fortnight has elapsed, and the committee as we are told, have elected neither of these gentlemen, but one who was not a candidate on the first occasion, and who possesses only one professional license, and they have given him a month's leave to enable him to get his second diploma. These circumstances, if correctly reported to us, seem well worthy of notice. We are far from desiring to clip the freedom of dispensary committees, or to bind them to select any candidate who may not seem to them suitable; but, on the other hand, we say that it would be perfectly improper and illegal for a committee to advertise a sham election, they having decided already to keep the place open for a friend, and we are under the belief that, in point of law, they have no right to adjourn an election as long as there are candidates possessing the statutory qualifications, unless they have set forth in their advertisement that the election may be postponed if the committee sees fit. It is obvious that, if such a proviso were made public, candidates would not incur the expense of presenting themselves in person, We believe that the Local Government Board has been addressed on the subject by one of the candidates, and we certainly expect that they will, at least, firmly discourage the appointment of an unqualified person pending his obtaining the qualification of which he is short.

ABSTRACT OF REPORT ON THE DISTRICT, CRIMINAL, AND PRIVATE LUNATIC ASY LUMS IN IRELAND

(Continued.)

PRIVATE ASYLUMS.

No alteration has taken place in the number of these establishments, which is precisely the same as in the year 1877, neither can we say that any feature of interest presented itself during the past twelve months, while as regards the patients locaated in them, they exhibited scarcely a variation—642 being under treatment on the 31st December, 1878, as against 636 at a corresponding date in 1877. A similar proportion holds good in the two preceding years; in fact, since 1874 there has not been a difference of 8 annually under treatment—a circumstance which indicates, so far at least as the better classes of society are concerned, that lunacy cannot be on the increase which is so much apprehended by the public. The admissions were 169, of which 143 were first attacks, and 26 relapses—males amounting to 77, and females to 92, making in all a total number under treatment of 804; the patients discharged during the year as recovered were 66—improved, 35—unimproved, 17—constituting an aggregate of 118, 46 being males, and 72 females. There were 44 deaths, equally divisible between both sexes.

Digitized by Google

We are happy to say that no fatality occurred from violence, suicide, or any accidental cause.

As a rule we feel justified in stating that a due attention has been bestowed on those entrusted to their care by the proprietors of these establishments, some of which, as we have remarked in previous reports, are on an equality with the best elsewhere. Others, however, do not afford all those domestic advantages and enjoyments which we could desire; but fairly taking into consideration the limited stipends not unfrequetly paid, and, as we are informed, the occasional difficulty in obtaining these stipends, a due allowance must be made for certain deficiencies.

No justifiable causes of complaint in regard to unkindness of treatment have been made known to us during the past year; while our frequent visits to private licensed houses afford ample opportunities to the individuals detained in them of communicating directly with the inspectors. It is, however, but natural to suppose that persons deprived of their liberty, possessed too, in many instances, of a considerable amount of intelligence, though subject to strong and fixed delusions, may naturally be discontented with their condition; as well as others who, by a recklessness of conduct out of doors, and their unaccountable demeanour and language at home, bring themmselves, at least for a time, within the category of those who are insane, and even dangerous.

There is also a third class—comprising individuals of both sexes—who, from an inveterate indulgence in spirituous liquors, forgetting all the duties of social life, and utterly disregarding truth and solemn promises of amendment, compromise their own safety. These placed under restraint in due legal form, and certified to be insane by competent physicians, cause much anxiety to public officers in the capacity of inspectors as to the period of their detention. In regard to such we can only exercise a conscientious discretion.

The clauses of the statute 5 and 6 Vic., cap. 33, under which private asylums are regulated, on the whole are fairly carried out, certainly without any culpable abuse.

Irregularities from time to time occur as respects the admission of patients on single certificates, but not being from improper motives, may be justified within a reasonable period. Anxious at all times to afford every latitude to the inmates of private asylums, we find it to increase from year to year, for patients, instead of being isolated and confined as formerly, are now frequently allowed to visit their friends for a definite time on probation.

We cannot, however, but think, and have long felt it to be the casse, that the fact of a member of a family being placed in a lunatic asylum, and his maintenance paid for, affords no excuse on the part of his relatives for subsequent neglect which, in our opinion, cannot but be deemed a grave omission, and quite as unjustifiable in mental as it would be in physical afflictions.

The four unlicensed houses for the reception of private patients being of a self-supporting character, and admiting certain inmates without payment—namely, Swift's Hospital, the Friend's Asylum, Richmond, under the management of religious sisters, and Stewart's Institution—continue to be conducted in the same praiseworthy manner in which we have hitherto represented them. The inmates of the last-named institution, formerly situated at Lucan, now occupy a very spacious, massive building, surrounded by some thirty acres of land, at Palmerstown, within five miles of the city of Dublin. Its past system of management affords the best security for its future and well-merited success.

Most respectfully submitting the preceding Report to your Grace,

We have the honour to be,

Your Grace's obedient servants,

JOHN NUGENT.
GEORGE W. HATCHELL.

Lunacy Office, Dublin Castle, May 26, 1879.

MALLOW DISPENSARY.

A MEETING of the committee was held for the purpose of considering the resignation of Dr. Berry, after a long service of twenty-two years as dispensary doctor. The secretary read the following letter from Dr. Berry:—

"Gentlemen,—It becomes my duty to tender to you the resignation of the post of medical officer of this dispensary district entrusted to me now almost 22 years ago, and which I had held as *locum tenens* for a considerable time previously. I take this step with great regret and reluctance; but being now in my sixty-third year, and the arduous nature of the duties, especially the night work, having begun to tell seriously upon my health, after an almost continuous occupation of the post since my appointment, I feel that increasing years, and consequent failing of strength, demand my retirement from them. In asking that you will take the necessary steps on this application, I cannot refrain from expreessing my deep gratitude and ackowledgments for the unvarying kindness and consideration ever shown me by the committee and all connected with the district.—I remain, gentlemen, &c.,

"PARSONS BERRY."

The Rev. W. C. Wills said that he regretted exceedingly the resignation of Dr. Berry, on account of the care and attehtion that he always took of the poor patients under his charge, and he felt assured that the poor would miss very much. He had personal knowledge of the care and anxiety that Dr. Berry entertained for all those poor people professionally visited by him.

Colonel Williamson said he was perfectly aware of the admirable manner in which Dr. Berry discharged his onerous duties in this large district.

The Chairman said that he issued a great number of visiting tickets, and was for many years on the committee, and that no complaint was ever made to him or to the committee of the way in which Dr. Berry discharged his duties, and that he, too, had personal knowledge of the faithful manner in which Dr. Berry discharged his duties to the poor of this district.

Sir James L. Cotter said that no one could discharge his duties in a more efficient manner than Dr. Berry did; he was aware of it himself, and he was told so often by the patients under his charge.

Mr. Nunan said that Dr. Berry was deserving of anything at the hands of the committee on accounnt of his great attention to his patients.

Mr. O'Riordan hoped that as large a retiring allowanc as the law would permit should be recommended by this committee to the guardians.

It was then carried unanimously—"That we beg cordially to recommend Dr. Berry's case to the favourable consideration of the board of guardians of the union for the full rate of superannuation allowed by law in such cases, and which we consider he is fairly entitled to, and request the board will take the necessary steps in filling the vacaucy in due course."

Dr. Berry then came into the committee room, and was apprized that the committee accepted his resignation, and recommended him to the full allowance he was entitled to. He returned thanks, and the meeting then separated.

TO READERS.

THE Editor will feel especially obliged by receiving copies of newspapers which contain any Poor-law or other intelligence of medical interest, in order that he may, if fit, republish it for the benefit of the readers of the *Medica Press*. Although twenty-one of the leading Irish newspapers are received at the Irish office, many things may escape notice which are deserving of attention. Newspapers should be marked, and addressed to Dr. JACOB, at the Dublin offices of this paper.

INCONSISTENCIES IN THE PRESENT ARRANGEMENTS FOR MARYBORO' GAOL.

THE Medical Officer has been offered £60 a year (3s. 3½d. a day) if he will, in addition to all the duties—new and old—appointed to his own office, undertake those of the apothecary—he being already obliged to perform some of those hitherto required from the chaplains, who are relieved of inspection of diets; and most of those hitherto required from the local inspector, who has been discontinued, and his salary economised.

In this prison the chaplains' salaries have, unasked, been increased as below:—

Protestant	...	from £20 to £60.
Roman Catholic		,, £40 ,, £80.

They are only expected to attend once on Sundays, and twice through the week, and daily only in the event of there being sick *ill enough to be in hospital.*

The medical officer must visit daily, any and all who are sick, *or so representing themselves, whether in hospital or not*, and those who are in punishment. He has to make general inspections, and more limited inspections at fixed and frequent intervals. To make examinations of persons (officers and prisoners), to certify as to their sickness or health, as the case may be. Investigate for certificates of lunacy. Investigate fitness for ordinary or extraordinary punishments. Examine candidates for appointments as warders and matrons. To certify for supplies—medicinal, dietetic, &c., &c.

All these duties practically involving daily visits, frequently more than one visit daily. The medical officer is not permitted the occasional aid of his assistant. His son has been refused admission to accompany him as a means of study, though an advanced student of medicine.

He naturally wonders why he is to be expected to perform the duties of *three* officers, and part of those of a fourth, for a wholly insufficient salary, when one chaplain has had his doubled, and the other his salary trebled, unasked.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF SEPTEMBER, 1879.

SEPTEMBER 1st.—Mahony, William Aloysius; Mitchelstown, co. Cork; Lic. 1879 and Lic. Mid. 1879 K. Q. Coll. Phys. Irel.

3rd.—Young, William Mussen; Lisburn, co. Antrim; M.D. Q. Univ. Irel. 1879.

5th.—Smyth, William; Lisburn, co. Antrim; M.D. Q. Univ. Irel. 1879.

9th.—Lecky, William Stuart; Mount Salus, Dalkey, co. Dublin; M.B. 1879 and B.Ch. 1879 Univ. Dub.

10th.—Maxwell, Robert Fawcett; The Mall, Armagh; Lic. R. Coll. Phys. Edin. 1879, Lic. R. Coll. Surg. Edin. 1879.

10th.—Beamish, Samuel, FitzRichard; Hedgefield, Inchageela, Macroom, co. Cork; Lic. R. Coll. Surg. Irel. 1877, Lic. 1879 and Lic. Mid. 1879 K. Q. Coll. Phys. Irel.

17th.—Beale, Thomas William; 17 Waterloo Place, Dublin; Lic. R. Coll. Surg. Irel. 1877, Lic. R. Coll. Phys. Irel. 1878.

19th.—Allen, Richmond Robert; 17 Brighton Square, Rathgar, co. Dublin; Lic. R. Coll. Surg. Irel. 1879.

19th.—Fitzpatrick, Thomas; Clones, co. Monaghan; Lic. R. Coll. Surg. Irel. 1878, Lic. 1879 and Lic. Mid. 1879 K. Q. Coll. Phys. Irel.

20th.—Collier, John David; Collon, co. Louth; Lic. R. Coll. Surg. Irel. 1876. Lic. K. Q. Coll. Phys. Irel. 1879.

20th.—D'Alton, Peter Reynolds; Lavallyroe, Ballyhawnis, co. Mayo; Lic. R. Coll. Surg. Irel. 1878. Lic. 1879 and Lic. Mid. 1879 K. Q. Coll. Phys. Irel.

29th.—Jones, Charles; 60 Rathgar Road, co. Dublin; Lic. Fac. Phys. Surg. Glas. 1868.

SANITARY SALARIES IN IRELAND.

WE are inundated with newspaper reports of the proceedings of boards of guardians, one and all in favour of reducing the salaries of sanitary officers, and of abandoning, if possible, all pretence of enforcing sanitary law. It would be unprofitable to reprint these proceedings, which, in many instances, have been met by forcible protests from the medical officers of the district.

We are able to state—which we do with satisfaction, and with every approval of the course pursued—that the Local Government Board has firmly refused to sanction the proposed reduction, and has communicated this decision by the following circular letter:—

"Local Government Board, Dublin,
"30th September, 1879.

"SIR,—The Local Government Board for Ireland acknowledge the receipt of minutes of proceedings of the Board of Guardians of Monaghan Union on the 24th instant, containing an entry of the board's letter of the previous day's date, relating to the salaries proposed to be allowed to the medical officers of health of the Union under the provisions of the Public Health Act, 1878, and a resolution postponing consideration of the matter for six months; and in reference thereto the Local Government Board desire to state that they must request the guardians to be good enough to proceed to the consideration of this subject without delay. Having regard to the fact that the duties of the medical officers of health have been increased by the sanitary order recently issued under the provisions of the Act in question, the Local Government have arrived at the conclusion—as intimated in their letter of the 16th inst.—that they cannot approve the reduction proposed by the sanitary authority in the salaries of those officers. The Local Government Board have at the same time to state that if the guardians adhere to their resolution on the subject of the proposed reduction, they will feel it necessary to exercise the powers vested in them by the 11th section of the Public Health Act, 1878, and to issue an order fixing salaries for the medical officers commensurate with the duties which they will now be called on to discharge.

"By order of the Board,

"B. BANKS, Secretary."

It will be observed that the Local Government Board herein distinctly recognise the fact already insisted upon by ourselves—that "the duties of the medical officers of health have been increased by the sanitary order recently issued"—and we hope that, wherever they may find it necessary to fix the salaries themselves they will act upon this view, and recognise the increased duty by reasonably increased remuneration.

PROPOSED ABOLITION OF THE CONSULTIN SANITARY OFFICERS.

The following letter has been communicated by the Local Government Board to the Mountmellick and Athy Guardians.

THE NEW SANITARY ORDER.

The Clerk read the following letter:—

"Local Government Board, Dublin,
26th September, 1879.

"SIR,—The Local Government Board for Ireland have had under their consideration the resolution of the Sanitary Authority of Mountmellick Union of the 20th instant, in reply to the Board's letter of the 15th instant, that the

Digitized by Google

Sanitary Authority are still of opinion that the salary of £15 is quite sufficient for the duties to be performed by the medical officers of health under the Public Health Act of 1878, and confirming their resolution of the 15th ult.

"In reference thereto, the Local Government Board direct me again to observe that, having regard to the fact that the duties of these officers have been increased by the new sanitary order, made under the provisions of the Public Health Act, they are unable to approve of the proposed reduction in their emoluments, and the Board must therefore request that the Sanitary Authority will be so good as to take the matter again into their consideration. If the Sanitary Authority should adhere to their resolution on the subject of the proposed reduction, the Board will feel it necessary to exercise the power vested in them by the 11th section of the Public Health Act, and issue an order fixing salaries of the Medical Officers of Health commensurate with the duties which they will now be called on to discharge.

"With respect to that part of the resolution of the Sanitary Authority of the 16th ultimo, in which it is proposed to discontinue the services of Dr. Clarke, as consulting sanitary officer, and appoint him Superintendent Medical Officer of Health, I am directed to state that if the Sanitary Authority had considered it advisable to retain Dr. Clarke, he would have continued to receive the salary previously paid to him. But if the Sanitary Authority think it necessary that he should be required to discharge the additional duties imposed by the recent order on the Superintendent Medical Officer of Health, and to report monthly on the general sanitary condition of the union, and on the discharge of their duties by the Medical Officers of Health, and the sanitary sub-officers, the proposed salary of £12 a-year would be insufficient remuneration for such important and responsible work.

"The Local Government Board therefore request that the Sanitary Authority will also take this subject into their consideration, and inform the Board of their views.—By order.

"B. Banks, Secretary.

"To the Executive Sanitary Officer."

IRISH MEDICAL ASSOCIATION.

Royal College of Surgeons,
Dublin, 30th August, 1879.

Re THE NEW VACCINATION ACT.

Dear Sir,—In accordance with the instructions of the Council of the Irish Medical Association, it is my pleasing duty to inform you that the "Vaccination Amendment (Ireland) Act, 1879," received the royal assent on the 15th inst.; and that the operation of its provisions commenced on the 16th inst.

The following are the changes which have just been made in the vaccination laws of Ireland, and they are worthy of your most attentive consideration :—

Section 3.—(*Verbatim.*)

3. "The father or mother of every child born in Ireland after the passing of this Act, or in the event of the death, illness, absence, or inability of the father or mother, then the person who shall have the care, nuture, or custody of the said child shall, within three months after the birth of such child or as soon afterwards as may be practicable, take or cause to be taken the said child to the medical officer of the dispensary district in which the said child is resident for the purpose of being vaccinated, unless he shall have been previously vaccinated by some duly qualified medical practitioner, and the vaccination duly certified; and the said medical officer shall and he is hereby required thereupon, or as soon after as it may conveniently and properly be done, to vaccinate the said child: provided that in the vaccination of children who are inmates of the workhouse or other public or charitable institution, the master, matron, or chief officer of the workhouse or other such institution shall take the steps required to be taken under the provisions of this Act by the father or mother of the child, or other person having the care, nurture, or custody thereof. The father or mother or other person having the care, nurture, or custody of any child born elsewhere than in Ireland, but brought into Ireland after the passing of this Act without having been vaccinated, shall be under the same obligation to have such child vaccinated as if the child had been born in Ireland on the day on which he was brought into Ireland."

You will observe that vaccination is in future to be performed within three months after the birth of children born since 15th August last, but those born previous to the 15th August cannot be required to be vaccinated before six months old.

The child, as heretofore, is to be brought to the Dispensary, or to a Vaccination Station, situate within the district in which the child resides, on one of the days appointed, and within the hours prescribed for the attendance thereat of the medical officer.

Section 4.—(*Verbatim.*)

4. "Upon the same day of the week following the day on which any child has been vaccinated as aforesaid, the father or mother, or other person having the care, nurture, or custody of the said child, shall again take or cause to be taken the said child to the medical officer by whom the operation was performed, in order that such medical officer may ascertain by inspection the result of such operation, and, if he see fit, take from such child lymph for the performance of other vaccinations; and in the event of the vaccination being unsuccessful, such parent or other person shall, if the medical officer so direct, cause the child to be forthwith again vaccinated and inspected as on the previous occasion."

The power to take lymph is now, for the first time, provided in Ireland, under a penalty of twenty shillings, upon the person refusing to allow it.

Section 5.—(*Verbatim.*)

5. "Upon and immediately after the successful vaccination of any child the medical officer or practitioner who shall have performed the operation shall deliver to the father or mother of the said child, or to the person who shall have the care, nurture, or custody of the said child, a certificate under his hand, according to the form in the first schedule to this Act marked (A.), that the said child has been successfully vaccinated, and also shall transmit a duplicate of the said certificate to the registrar of births and deaths of the district within which the birth was registered; but if after due inquiry such district is not known to the medical officer or practitioner, or if the birth of the child has not been registered, to the registrar within whose district the operation has been performed; and such certificate shall, without further proof, be admissible as evidence of the successful vaccination of such child in any information or complaint which shall be brought against the father or mother of the said child, or against the person who shall have had the care, nurture, or custody of such child as aforesaid, for non-compliance with the provisions of this Act: Provided that if the medical officer of any dispensary district is also the registrar of births and deaths of that district, it shall be sufficient for him to sign one certificate, to be delivered to the father or mother, or other person as aforesaid, and to register the fact of such vaccination in the manner provided by the vaccination (Ireland) Acts."

THE ADVANTAGES OF CALOMEL IN THE DISEASES OF CHILDHOOD, WITH ESPECIAL REFERENCE TO TYPHOID FEVER.

By E. MARLETT BODDY, F.R.C.S., F.S.S., etc.

(*Concluded from page* 305.)

All probably would go well if we were to administer a purgative, such as calomel and its adjunct, castor oil; but no, we repudiate them, and, on the contrary, we inject into the rectum an enema of starch and opium, while at the same time we force down the hapless patient's throat as much nourishment as it is possible for him to swallow. What would be the consequence, let me ask, if the drain-pipe of a dwelling house were to be plugged up? Ten to one it would burst, and the whole apparatus connected with it would be in complete disorder. A plumber is naturally sent for, and he very speedily puts it all to rights; not by further plugging up one end and filling in the other, but he proceeds immediately to cleanse the pipe right through, so that no impurities shall be left behind; but we, with our superior science and knowledge, pursue a very different course. We proceed to block up one end and fill in the other, and the natural result is that the system breaks down, and the patient dies from typhoid fever, which has originated, some would say, from the gases of an old cesspool, or the secretion of a cow.

All these symptoms to which I have especially alluded, point conclusively to the fact that typhoid fever originates from an overloaded irritable state of the intestines; for constipation and its concomitant symptoms which occur in the premonitory stage, and the appearance of diarrhœa during the *first* week, are to a certainty indicative of such a condition, whether the fever arises from typhoid excreta or from the emanations of drains; and as there is only one efficient remedy for constipation, and as diarrhœa is almost sure to follow if it is unattended to, therefore the best plan is to administer that remedy in the premonitory stage, and to avoid what may be designated the expectant treatment. The remedy is active purgation; which will not only modify considerably the severity of the fever, and perhaps prevent it altogether, but an entirely different state of affairs will occur. If we immediately come to the conclusion that it *must* be a case of typhoid fever, because perhaps some other cases have appeared in the neighbourhood, instead of regarding the matter as simply bowel irritation, resulting from neglect, we at once suspect the milk, or we search for a cesspool; we look askance on the drains, or we very adroitly trace the cause to an isolated case, or to other media of contagion; and then, having once decided that it is a case of typhoid fever, we treat it according to the present recognised plan, and lose sight of, or ignore *in toto*, the state of the alimentary canal; and when at last the expected inevitable diarrhœa makes its appearance, we resort to the strongest astringents with the intention of stopping or moderating it. We overpower the system with nourishment which is not needed, or, as I have said before, we endeavour to plug up one end and fill in the other; we wait patiently for the rose-coloured spots; we scrupulously take the temperature night and morning; we use a chart on purpose to trace its variations; we examine the excreta to see if they present the typhoid appearance; we detect the gurgling in the right iliac region; we test the urine for albumen; we feel the pulse regularly at every visit; we auscultate the chest, we clear out the room; we place disinfectants to obviate contagion; the excreta are removed because of their supposed infectious natnre; we examine the tongue and find it foul; we see that the patient is gradually sinking; the diarrhœa continues in spite of our astringents; the urine decreases in quantity; is loaded with uratic and phosphatic deposits, and becomes strongly ammoniacal; the breath is offensive, the appetite fails daily, and the head gets worse. These symptoms increase in severity, but we still persevere with our astringents; still we force in nourishment, and

Digitized by Google

very likely add brandy, port wine, or champagne, when cold water would be more beneficial; and probably our patient dies from typhoid fever, though, had we in the premonitory state pursued a different plan, and administered a purgative, such as calomel, combined with careful and judicious treatment, typhoid fever (which had originated from milk, or from the emanation of drains, or from water, or from any other source, for on this point we have not yet arrived at any decision) would very likely have been nipped in the bud.

If, instead of *making* it a case of typhoid fever from the beginning, we had regarded it merely as the result of a neglected condition of the bowels, and had administered a few powders consisting of calomel, followed by castor oil, or combined either with rhubarb or jalap, we should have found that, notwithstanding the milk, the cesspool, the water, or the drains, the case would have assumed a very different phase, and a very different termination.

Regarding the severity and modification of the attack, a great deal naturally depends upon the constitution and surroundings, but still they are only secondary, and should not engage and detract our attention too much, for if typhoid fever shows itself either in the palace, cottage, or garret, whether in town or country, we have one predominant symptom, viz., constipation with its co-existent evils, and its successor, diarrhœa, or the efforts of Nature to overcome the difficulty.

As there is no denying these facts, and as I have in various parts of my paper pointed out the considerable advantages to be reaped from the administration of calomel in constipation and diarrhœa, and in several other conditions, it would be useless going over the ground again. However, the action of this invaluable, though much abused, drug is as beneficial in typhoid fever as in other exanthemata, whether scarlet fever, small-pox, or measles. It is even more so, in my opinion, because typhoid fever springs from intestinal causes.

In all diseases, and particularly in fevers, there are three outlets for the elimination of the poison (in fact, in health they are the media for casting off what I may call animal refuse), viz., sweating, micturition, and defæcation, and there is no doubt but that one is as important as the other, prevent one performing its functions, and we very soon find that the whole system is speedily out of gear, for mischief next to ineradicable is bound to result: if we prevent sweating, fever immediately follows; therefore we strive as much as possible to promote diaphoresis, because it is a great relief to the system, and, consequently, it is regarded as a favourable omen in fever. If we were foolishly to take steps to prevent micturition, the result would be that in a short time dropsy, in some form or other, would make its appearance, or very likely a greater evil would arise, viz., extravasation of urine owing to the rupture of the bladder; but, marvellous to say, when Nature strives to relieve herself of an irritating intestinal load, we become alarmed, and endeavour to stop her from performing her duty, forgetting that defæcation is as important to health as eating, and that diarrhœa, which always succeeds an aggravated state of constipation, is conducive to a speedy recovery, and, in fact, it is the only considerable outlet whereby Nature can eradicate the effects and remains of disease.

What man in his senses would attempt to prevent sweating, when such is beneficial? or check micturition, or take steps that his patient should not eat nor drink? I am sure he would be denounced in no very elegant terms, and yet, when Nature exerts her powers in the necessary direction, and promotes the action of the intestines, we at once resort to certain measures in order to thwart her designs, forgetting that disease is eliminated *per anum*, as well as by other media. Such a proceeding appears peculiarly unaccountable, diametrically opposed to the laws of Nature, and pre-eminently unscientific, though it is the received opinion of the present day that it is just the reverse. A certain philosopher saith that "art, therefore, whenever it offers violence to Nature, in order to conquer, subdue, and bend her to its purpose, by tortures, and force of all kinds, seldom obtains the end proposed." If sweating is regarded as a favourable sign in fever, purging must be equally so, and if we do not purge Nature will, for a certainty, do so on her own account; if micturition is necessary, and I do not think that anyone will deny it, purging must be also: we give medicine to promote diaphoresis; we give medicine to promote the action of the kidneys, we give medicine to promote appetite, and yet, with all our boasted skill, no sooner does diarrhœa show itself, than we very methodically endeavour to counteract that which is most important, and which in febrile disease is really the main outlet for its elimination.

As to assert that purgation is weakening, and that it is highly injudicious to resort to it, and more especially in typhoid fever, I certainly do not see the reason nor force of such an assertion: relieving a man of a load is rather beneficial than otherwise; we certainly do not make him weaker: when the bladder is full, relief is only to be found in emptying it, and if there are some irritating fæces in the intestines, relief is only to be found in their ejection, and, therefore, Nature does this for herself in the shape of diarrhœa.

I hope I have proved conclusively that the present treatment of typhoid fever, whatever arguments may be advanced in qualification of it, is entirely opposed to common sense; for the fever thereby, instead of being modified, is aggravated and lengthened. I have drawn the reader's attention to two principal facts, which prove that this fever solely originates from some intestinal mischief, as its old name (enteric) implies; but whether that mischief originates from contagious matter, or, otherwise, I leave willingly to be discussed more fully by others abler than myself.

I have been necessitated more than once to revert to the contagious or non-contagious nature of typhoid fever, and to some of its supposed origins. I have simply endeavoured to prove, that as it springs from intestinal causes, we should, therefore, devote all our attention towards discovering by what mode the causes (whatever they may be) can be removed with the greatest facility, rather than endeavouring to elucidate what are the sources or media by which typhoid fever is spread and communicated. I have also striven to impress upon my reader that it is by means of purgation, and not by the administration and injection of astringents, that the elimination of the disease is actively brought about, and that, consequently, the ejection of intestinal contents is fraught with results highly conducive towards the patient's recovery. I have likewise drawn the reader's attention especially to calomel, as a drug peculiarly adapted to diseases incidental to childhood, and particularly so in the exanthemata. I have besides, in my observations on the treatment of typhoid fever, alluded many times to this purgative and cholagogue, and that it can be given with great advantage both in the premonitory stage, and also during the first week of the appearance of the diarrhœa, and, indeed, that it can be given from the commencement to the termination of the disease. The reader's attention has also been directed to the fact that its purgative qualities can be further promoted by castor oil, or by combining it with jalap or rhubarb, for, as I have said before, in typhoid fever, purging is the principal eliminator of the poison, besides being the speediest and safest treatment to pursue.

I bring my remarks to a temporary conclusion, as I hope at some future date to draw the attention of the profession to the treatment of typhoid fever especially, as I find it is a subject far from being exhausted, and I do not wish to extend my treatise beyond its intended limits.

SPINAL CURVATURE TREATED BY COCKING'S PORO-PLASTIC JACKET.

By LAMBERT H. ORMSBY, F.R.C.S., M.D.,
Surgeon to the Meath Hospital, and Co. Dublin Infirmary, and Surgeon to the National Orthopædic and Children's Hospital, Dublin.

THE treatment of spinal curvature, whether lateral or angular, has received of late a great amount of attention,

Digitized by Google

and some writers on the subject still cling to the old form of treatment, viz., the stationary or reclining board method; more modern writers, however, believe that such measures are debilitating, and say it defeats the main object it is supposed to carry out by inducing sedentary habits, and completely denying the patients fresh air and out-door exercise, which they so much require in such cases. The steel mechanical spinal support has its advocates, and is still very much used, notwithstanding a method of treatment introduced into these countries by Sayre, an American surgeon, about four years since, and called by him the plaster-of-Paris method, which was supposed by many to be superior to any line of treatment then known, or ever suggested. This treatment seemed to be so simple, so easy of application, and so thoroughly efficacious, according to the well-known American surgeon who introduced it, that nearly every surgeon having cases of the kind was induced to recommend it, then to try the plaster-of-Paris jacket, and I fear from the universal and indiscriminate adoption of such a method, it soon became over-rated and all the rage, but soon its supposed efficacy began to wane. Many cases treated by this method turned out a great disappointment, in fact, they were not cases in which such a line of action was at all suitable, and I feel, from what I know of the subject, that very shortly the plaster-of-Paris treatment for spinal curvature will be a thing of the past, and I therefore wish to draw attention to a treatment which appears to me to be very practical, simple, and easily applied, and I would further add, in my opinion, far superior to the plaster-of-Paris method. I allude to the application by Mr. Cocking, of Plymouth, of the material called poro-plastic felt for the manufacture of spinal supports in all forms of spinal curvatures. Mr. Cocking, who was present at the meeting of the British Medical Association in Cork, where he attended for the purpose of giving practical public demonstration of his method in Ireland. On his return through Dublin, he visited the National Orthopædic and Children's Hospital, Adelaide Road, where he found ample material, in the persons of children suffering from all forms of spinal curvature, to demonstrate the efficiency of his treatment, which he described very briefly as follows—in the presence of a large number of the profession and others interested in the subject: The felt is a brown or light yellow material, very limber and soft when exposed to the action of steam or confined in a hot air chamber, at a temperature of 180 deg. Thus pliable, it is quickly applied to the trunk and pressed to any shape, so as to fit the contour of the body, and on cooling, which it does almost immediately, it maintains the shape previously adapted.

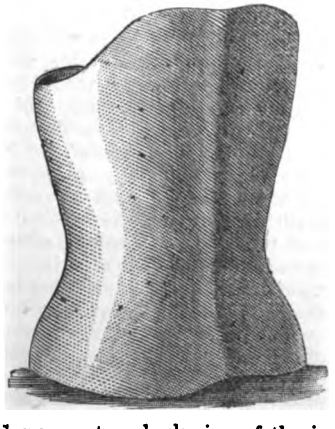

FIG. 1 represents a back view of the jacket.

The jackets are moulded, in the first instance, in the shape of an hour-glass, and made in all sizes—to suit any age. When a case comes before you, you should roughly adapt a jacket to the case, one that you think, from the size, will fairly fit when softened and moulded. The patient is suspended in a tripod or hook in the ceiling, with head and arm straps, so as to extend the spinal muscles, and take all superincumbent pressure off the weakened spine as much as expedient, and a tightly fitting

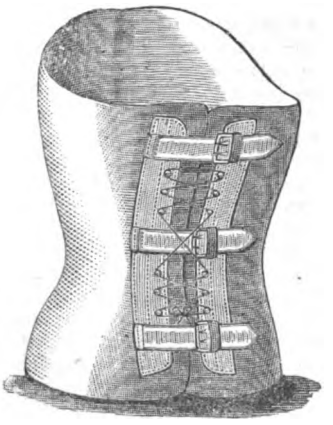

FIG. 2 represents a front view of the jacket.

woollen vest is applied: the poro-plastic jacket is then either softened in a hot-air chamber, or in an oven, or over a large vessel of boiling water, with a quantity of steam issuing therefrom; when soft and pliable, the jacket is quickly applied to the body over the vest, and rapidly moulded to the trunk whilst the patient is suspended.

FIG. 3 represents a jacket applied in a case of lateral curvature.

As the treatment of spinal curvature must, of necessity, be a very gradual one, the same jacket can be softened and remoulded over and over again, to suit the gradual return of the proper normal curve of the spine. It is fastened in front by straps and hooks, and in shape resembles a well fitting stays. For lateral curvature of the spine a jacket can be easily taken and moulded, without any special direction, more than what has already been given. All that is required is to give the circumference, and the size of thorax at the level of the axillæ, the size of the centre of the waist, and the size of the body on a level with the anterior superior spinous process of the ilium, and the length of body from axilla to anterior superior spinous process of ilum. With these measurements an instrument maker ought to be able to send a

Digitized by Google

jacket which would, in all probability, fit, when subjected to the softening process.

For angular or posterior curvature the case is different, the jackets must be made *specially*, and a plaster-of-Paris mould must be taken in the first instance; this mould or case must be filled with plaster-of-Paris so as to take exactly the true form and configuration of the curvature, so as to arrive at the point of angularity, and the situation where inordinate pressure must not be exerted, and provision for such made accordingly, so as to prevent pressure sores, &c. When the plaster cast is taken it must be forwarded, through an instrument maker, to Mr. Cocking, Plymouth, who, in the course of a week or ten days will return a jacket to the required measure, with a soft form of felt, subjected to a different process, inserted in the jacket, and placed over the point of angularity. In some cases of angular curvature I have had portions of the jacket removed, and chamois leather inserted in its place so as prevent pressure sores over the extreme point of angularity. When the angularity occurs in the cervical region a jury-mast must be attached, as in fig. 4.

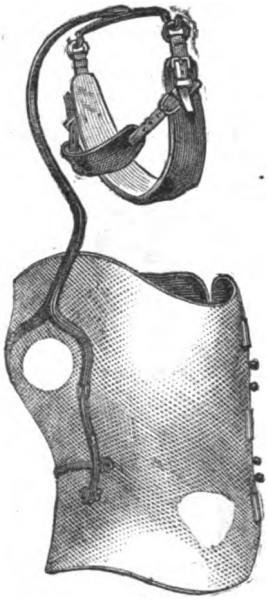

Fig. 4.—Jacket for angular curvature, with jury-mast attached. The parts indicated by the white spaces are left perfectly soft, so as to avoid all pressure on the point of spinal angularity, and the crest of the ilia.

In a letter received from Mr. Cocking, the following observations occur: "I hold that no mechanical support can equal felt properly applied. Either for efficiency, certainty, and re-adaptation, and not least, the ease with which the surgeon can use it without the aid of surgical instruments, this latter, in remote places, must be an immense advantage."

The following case, out of a number it has been applied in, is worth while recording:—

Thomas Mc—, æt. 11, suffering from posterior spinal curvature mid dorsal region, a delicate looking boy, walks with a very unsteady gait, and the body is in a very bent and stooped condition. Mr. Cocking took a plaster cast of the curvature at the time of his demonstration, he has since sent the jacket with the softened felt applied over the extreme point of angularity, and the boy has had it applied for some weeks, and expresses himself highly delighted with the support it gives his back, at the same time since it is so light and easily applied, he walks much more erect, and with a much steadier mode of progression. I might mention this boy had been previously treated with plaster-of-Paris without any improvement in his condition, although a fair trial had been given to the method.

It this method is carried out with care and discrimination, I believe it will soon supersede any other treatment yet recommended. It will be found to embrace the following advantages:—

1. Ease and cleanliness in application.
2. Lightness and porosity of jacket.
3. Inexpensive for ordinary cases—where the jacket need not be specially made, it ought to be supplied for hospital cases for about 10s. or 15s.
4. Power of the same felt jacket to re-adaptation over and over again, as the case improves.
5. Being removed easily, ablution and gymnastic exercises may be carried out when necessary.

This last point is of paramount importance, when compared with the plaster-of-Paris jacket. The latter jacket when kept on for a fortnight or three weeks at a time, contains myriads of vermin induced by the warmth and pent-up perspiration—with the poro-plastic jacket, which is removed every night, such a thing is not known.

To make the poro-plastic jacket as perfect as possible—

1st. In places where it is not necessary for the jacket to be excessively firm, I would recommend it to be perforated by little circular holes—this would lighten it, and also make it cooler in very warm weather.

2ndly. I would recommend arm straps, passing over the shoulders, so as to keep the jacket up, for I find it is inclined to slip down on the pelvis, and likely to impede the person walking, or produce pressure-sores from friction. With these two simple suggestions, as far as I have seen, I have every reason to recommend the treatment. In conclusion, I may add, that Mr. Fisher, F.R.C.S., has at the National Orthopædic Hospital, London, applied a large number of these jackets, and he considers them most efficient; an opinion in which, from my experience, I entirely concur.

Mr. F. Gustav Ernst, the eminent instrument maker, 80 Charlotte Street, Fitzroy Square, London, W., has supplied some of the neatest Cocking's jackets I have seen, and he will forward an illustrated pamphlet, containing full instructions, on application. The jacket may also be obtained from the different instrument makers in Dublin.

NOTE ON OZÆNA.

By LENNOX BROWNE, F.R.C.S. Edin.,
Senior Surgeon to the Central London Throat and Ear Hospital, &c.

The recent publication in this journal of "Late Suggestions on Ozæna" induces me to make a few remarks on that obstinate, and in every sense disagreeable, malady. It is very evident that the three authors quoted have different ideas of the significance of the word, which in reality should be applied to any form of nasal disease giving rise to unsavoury odour—the *punaisie* of the French, and *stink-nase* of the German. Many surgeons, however, limit it to those cases in which there is really ulceration of the mucous surface covering the turbinated bones, or actual disease of the bones themselves, with thickening, but without loss of tissue, of their coverings. My belief, founded on experience, is that the former is *only* found in syphilitic cases; while the latter may be frequently met with in young persons of strumous diathesis, in whom it is difficult to make out a syphilitic history, if, indeed, such at all exists, as well as from other causes, outside present consideration. Thus far I agree with Dr. Fränkel; but I join issue with him if, as I understand from the note in the *Medical Press*, of September 10th, he denies the connection of pharyngitis sicca with ozæna; for in my opinion, a large proportion of these cases arises entirely from the inspissation, retention, and consequent putrefaction of the normal secretion; the condition being the direct result of a long-neglected pharyngeal and

Digitized by Google

post-nasal catarrh. In admitting that this state of things is often associated with a strumous constitution, or an anæmic dyscrasia, is only to say that such complications render the subject of them more liable to catarrh. The ozæna is not therefore a coincidence, nor a casual connection of the pharyngitis sicca, but a direct result thereof.

In regard to Dr. Massei's parasitic origin, the same difficulty which occurs to me in considering such as the cause of diphtheria, comes to my mind in this connection. Given a putrid surface, and one will always find parasites. The more extensive the diphtheria, the more advanced the ozæna, the larger the quantity of parasites. It may well be asked—are the parasites in the van or in the rear of the disease? In my opinion they are the result, not the cause.

In the third note of Dr. Dawosky it is stated that he carefully removes all crusts. How is this done? I believe the only way is to remove them by emollient post-nasal washings, vapour or spray inhalations, or inunctions. They should never be removed by any method involving hæmorrhage, which must always lead to reformation of the crust, and by whatever process they are removed, measures should be taken to prevent their re-incrustation. Nothing is better for this purpose than an ointment of vaseline with iodoform, which I prescribe as follows :—

℞ Iodoform, gr. 5 to gr. 8 ;
Ether, fl. dr. j. to fl. dr. iss. Solve et adde
Vaseline, ℥j.;
Ottar rosæ, ♏v. to ♏viij.

In post-nasal douches I use about five to eight grains of chloride of ammonium, on account of its largely diffusing power, and an equal quantity of borax with a little glycerine, with or without carbolic acid, to about four ounces of water at 95° F., this amount serving for two douches with my post-nasal syringe.

For vapour inhalations, either pine oil, creasote, or benzole, in water, at 150° F. should be inspired by nose as well as by throat. To whichever is prescribed, aldehyde in no larger proportion than one drop to each inhalation should be added, this drug having a peculiar and quite specific effect on favouring fluid secretions in cases of inspissated mucus, and if administered in larger doses it is apt to produce headache or embarrassment of breathing.

On two or three points I must express my strong disagreement with Dr. Dawosky :—

First—I never plug the nostrils, but endeavour to do all I can to favour free nasal respiration.

Secondly—I never employ pure glycerine, because of its powerful attraction for water, which increases the dryness already complained of.

Thirdly—I never employ alum, tannin, or any other astringent for the same reasons, nor do I ever recommend nasal snuffs, believing that such are contradictory of the physiological function of the nasal organ.

Dr. Massei speaks of the local application of calomel powder to the ulcerated surfaces, and Mr. Nixon in last week's issue of the *Medical Press* relates an instructive case, in which rapid and profuse salivation, with discharge of the vomer, followed this procedure. I have just now under treatment a similar case, with both pharyngeal and palatal ulceration, fissured hard palate, and nasal disease. The plan pursued has been that recommended above, viz., internal administration of iodides, local application of solid nitrate of silver to the pharynx and palate, post-nasal douches, and application of a solution of sulphate of copper to the nasal ulceration, and constant inunction of the nostrils with the iodoform and vaseline. Now at the end of five weeks the patient is nearly well, both palatal and nasal ulcerations being all but healed. It may be interesting to add that in this case, as in many others, the iodide of potassium even in such doses as three grains could not be borne, but five grain doses of the iodide of sodium caused no disturbance, and have all the good effects of the potash salt.

Lastly—I never use nitrate of silver in any form of throat disease, except in syphilitic ulceration, to be then applied to the exact spot in the solid form. Even in these cases I have largely superseded its employment by substitution of the galvano-cautery, acid-nitrate of mercury and sulphate of copper. I have been led to this elimination of the silver applications, and would urge the same on all my professional brethren, because I have never seen any benefit pertaining to them which the other remedies did not enjoy, and because I have personal knowledge (independently of information of others) of two cases in which permanent cutaneous disfigurement has followed their use in throat affections.

For disinfectants I prefer the salicylates, thymol and sanitas, to permanganate of potash on account of discolouration of skin and linen caused by it, and to carbolic acid, on account of its—to many—objectionable flavour. As lozenges, none are superior to Wyeth's compressed chlorate of potash, or chlorate of potash and borax, unmixed with any sugar, or mawkish fruit paste.

As regards dilatation, mentioned as necessary by Dr. Massei in those cases in which the passage is obstructed, the surgeon must try to reduce mucous thickening by the local remedial measures already indicated, and remember that instrumental introduction is but too likely to lead to ulceration of the already turgid and congested coverings. In more advanced cases when the stage of atrophy has been reached, the passages, already too open, do not require further dilatation, but rather stimulation to promote healthy submucous nutrition.

Where there is actual ulceration I have had good results from application of the galvano-cautery, carefully made by means of a strong reflected light, and I have never had occasion to perform the operation of exposing the cavity and removing portions of the bone.

Finally, therapeutic attention to the particular dyscrasia is of great importance, and it is worthy of note of how great service is iodide of potassium, combined, often, with iodide of iron and cod-liver oil, in cases of a strumous nature, where, as at the commencement stated, it is difficult to make out a syphilitic history. In a large majority of the same class of cases, small doses of perchloride of mercury afterwards given, or alternated with the iodide, have the best effects, but I am by no means prepared to say that even with so specific a treatment the cases which derive benefit are of the specific nature which many surgeons would therefore ascribe to them. I am happy to be able, in conclusion, to agree with Dr. Massei in urging the importance of persistence in the treatment of these cases. In no disease does so sure a reward of patient perseverence in well-doing result.

Special.

PAUPERISM AND COMPULSORY PROVIDENCE.

II.

WHAT a simplicity marks the basis upon which our Poor-laws are constructed! "You should do unto others as you would that others should do unto you." This is the great principle upon which our Poor-law statutes are framed, and upon this theory the State undertakes to feed the hungry, to clothe the naked, to comfort the afflicted, to relieve the sick, to protect the fatherless, to help the widow, to find employment for the unemployed, and to punish the drunkard and the dissolute. Whitbread said, we believe, that the Act of Elizabeth might be considered the *bible* in this respect. We know now how the plans so ably devised by statesmen of the highest eminence have proved imperfect, for we have—as the almost universal consensus of opinion on the failure of the Poor-law—thousands of pamphlets containing propositions for ameliorating the condition of our poor, for preventing poverty from descending into indigence, for improving the moral habits and increasing the comforts of the labouring population by com-

Digitized by Google

binations of the regulations of political economy, and the application of its best principles.

Whitbread said further: "It is an assertion now pretty generally made that the system of our Poor-laws has served to degrade those whom it was intended to exalt; to destroy the spirit of independence throughout the land; to hold out hopes which cannot be realised; to encourage idleness and vice; and to produce a superfluous population, the offspring of improvidence, and the early victims of misery and want. That which in speculation ought to have been our glory has been turned to our reproach."

These words were spoken in 1807, in the House of Commons. Our Poor-laws still are open to the same reproach made fifty years ago.

Returning to Mr. Blackley's paper and suggestions on the remedying of pauperism, we take up his scheme of compulsory providence at some of the most important objections raised against it, which may thus be summarised:—(1) The smallness of the provision made; (2) compulsory provision might give the impression that it was needless to save more; (3) existing improvidence is not as great as Mr. Blackley makes out; (4) opposition will be experienced from existing societies; (5) collection will be impossible; (6) there will be a large number of recalcitrants; (7) malingering will have to be dealt with; (8) management would be expensive; (9) employers would be further taxed; (10) it would not provide for sudden loss of labour and unexpected disasters.

Mr. Blackley has met all these objections in an able and argumentative manner. He believes that his scale would enforce a *minimum of provision*, without giving an impression that all had been done in the way of saving; whilst he confirms by statistics the existence of a wide-spread improvidence, at the present time only imperfectly met by burial clubs and friendly societies. He does not think that much opposition may be expected from sound friendly societies; for the principle on which they exist is to secure the providence of the poor, and their managers are logically bound to approve of the principle of national insurance.

With great truth and force he adds: "Now let us turn to another class of society. To those, viz., which under the false name of friendly are the poor man's bitterest foes, that exist to swindle, plunder, and defraud the ignorant and helpless; that look for large profits from the simplicity of the poor; that in order to keep their funds high, cut off, as the newspapers lately recorded, the insurance of £7 due, on his wife's death, to a member of thirteen years' standing, because the poor woman's last illness, preventing her going to pay, had brought the contribution *one week into arrear*. In fact, let us look to the bad and unsound friendly society, that lives by sucking the very heart's blood of would-be independent working men, while leaving them to the pauper's *dole*, and workhouse in the end. I defy them to oppose the National Club on any ground but the plain and patent one of selfish interest."

He next considers its practicability as regards collection, recalcitrants; and observes in reference to the objection "they will enlist and so evade their payments," "With all my heart I answer, 'I wish they would,' and certainly they should have the choice if not the compulsion; but so far from thereby evading their payment they would be passing, as the proverb says, 'out of the frying-pan into the fire.'

"For up to a certain time of life individual providence by deduction from wages is compulsory on every soldier in the service. He is obliged to put aside 2d. each day from his pay, so that when his six years' term of service is over, he receives his savings to the amount of nearly £20. Let the refractory young tramp or thief fly for refuge to the army to avoid insuring, and he does the very thing he is wanted. He will be well fed, and clothed, and taught; he will have a chance of a new start in life; he will be a member—he may become an honoured one—of an honourable profession; he will have learnt cleanliness, comfort, and self-respect; and if he like, when his three years are past, his own money, which he never missed, will pay his insurance; and the once poor, slouching, hopeless, pauper, vagabond, may march forth an honest, independent man, able morally to hold his head up among his fellow men, as he has learnt to hold it up literally before his comrades on parade."

Mr. Blackley disposes of the question of coercion and its cruelty by the following suggestive extract from the Local Government return for 1877-1878:—"Mean number of paupers receiving relief, 719,849; cost of relief given, £7,400,034." A very simple division gives the annual cost per pauper to the nation as reaching £10 5s. 6d.

Let anyone balance the cruelty of aiding a law-defying lad to lay by £10, once for all, for himself, against that of burdening the community with a larger sum on his behalf, for every year that he is allowed to remain a pauper.

After discussing a few minor objections, he dwells on the risk of loss by malingering, which he does not apprehend will create any more difficulty than that now experienced from it by existing friendly societies; whilst he admits that no system can provide against unexpected disasters. He thus concludes: "I have tried to meet every important objection which has been offered against national insurance. I do not believe there is one amongst them insurmountable, though it would be overweening self-confidences to hope I had made all my readers share this faith. But it is no reason, in a matter of such importance as this is, because I fail to remove an objection, that many wiser men than me should fail as well. This, at least, I claim to have made out so far—that the change I propose is not impossible, at all events, till far stronger grounds for the contrary opinion than any yet adduced shall be brought forward.

"Let any reader of this paper compare the vastness of the good which this scheme would effect with the small importance and logical weakness of the objections to it we have considered, I think he will agree with me that we have a right to ask some better reason for having to go barefoot than that some day a boot-lace may be broken; or for having to sit always in darkness some better reason, than that clouds occasionally obscure the sun."

In conclusion, we must take a rapid survey of what has been done for the working classes in the way of encouraging thrift. In every part of England we have penny and Post-office savings banks, benefit and insurance societies, building and money clubs, trade societies, lying-in charities, provident dispensaries and sick clubs, for their special benefit. It would be unfair to say that these institutions have not been productive of good. They have encouraged providence, and at the present time there are thousands and thousands of working men who are possessed of property and money, which they have saved in consequence of the facilities they have of putting away small sums, from a penny to a pound. But they have not done the good they ought to have done, nor have we the results we might expect. Mr. Blackley's article will do good in directing attention to the necessity of reform, and in stimulating the cause of thrift. We must express our strong and firm conviction that something must be done to check the tide of pauperism. We hold it criminal, considering that we have such societies as the Oddfellows and Foresters, that any working man should not belong to a club, and when sickness and destitution come on through neglect of this cheap ordinary provision, we have no sympathy with the workman who has to appeal for aid either to our voluntary charitable agencies or the Poor-laws. We doubt the feasibility of instituting a national insurance club, as devised by Mr. Blackley, though we wish the venture success.

CLINICAL SOCIETY OF LONDON.

Inaugural Meeting.

The First Meeting of the Clinical Society for the present session was held on Friday last, the 10th inst., Dr. Headlam Greenhow, President, in the chair.

After a short congratulatory address from the President,

Dr. Douglas Powell read a Report of a

case of leprosy with enlargement of the glands,

which he had exhibited at the Society last session, and upon which a committee of observation, consisting of Drs. Cayley, Dyce-Duckworth, and Liveing, with himself, was appointed. The case had been placed under Dr. Powell's care by Surgeon-Major Porter. When shown at the Society the man's clinical

Digitized by Google

features presented were considerable, somewhat mahogany-coloured, pigmentation of the skin, and especially of the legs, marked thickening of the lips and lobes of the ears, and a corrugated thickening of the skin over the brows and occiput, which gave the patient, aged 24, the appearance of a man much older; and the "leonine" aspect, characteristic of leprosy. The hair had almost entirely disappeared from the head, face, and surface of the body, and a papulo-squamous eruption covered the entire surface of the trunk. There was still marked enlargement of the glands, especially of the axilla and groins, although in this respect the patient had greatly altered for the better since his portrait was shown at the Pathological Society six months previously by Mr. Porter. The disease had first made its appearance when serving with his regiment in India in December, 1876, when he had "rupia," followed by a scaly skin affection, with loss of hair, for which he was treated with anti-syphilitic remedies. The glands of the neck first, but soon also of the axilla and groins became enormously enlarged, whilst the patient steadily emaciated and lost strength. This downward course continued, notwithstanding good diet with fruit and vegetables, iron, and cod-liver oil. For four months after he was admitted into Netley Hospital, until in May, 1878, Mr. Porter placed him on cod-liver oil containing 1-10th gr. of phosphorus. His condition then began rapidly to amend. He gained weight and strength, whilst the glands steadily diminished in size. He was admitted into Middlesex Hospital under Dr. Powell's care, in January, 1879. Careful observations were made by the committee as to surface sensibility, but no anæsthesia made out. The nerves at the bend of the elbows were slightly thickened, and small characteristic ulcers were present at the right wrist and left great toe. The urine was natural; the temperature normal. He was placed on gurgin oil, and for six months appeared to be doing well. The blood examined was found to be rich in red corpuscles, and to contain no filaria nor excess of white discs. At the end of the first week in March, however, the patient had severe rigors; the temperature went up, and an erythematous patch appeared at the left elbow, which rapidly extended day by day, so as to attack in turn the whole surface of the body and extremities. This spreading erythemata was complicated by broncho-pneumonia, and attended with typhoid symptoms; and finally albuminuria set in, and the patient died on March the 30th. At the post-mortem examination fibroid induration of glands, broncho-pneumonia, with some cicatrices and indurated patches in the lungs, marked fatty degeneration of the liver, and recent nephritis, were found. No disease was apparent in the ulna nerve or its ramifications, as examined by the unaided eye, and the internal glands were not notably affected. On minute examination, however, some early changes were observed in the nerve; also fibroid thickening of the skin, with small-celled growths or deposits, and fibroid degeneration of the glands. The committee in their remarks observed that the case in its clinical features was one of elephantiasis græcorum, remarkable chiefly in two respects, viz., the great enlargement of superficial gland—a certain degree of such enlargement being not uncommon—and in the amendment of the condition apparently under the influence of phosphorus. Secondly, in the termination of the case by such an extensive erythematous inflammation of the skin, patches of this disease being again not uncommon as a complication of this disease. The microscopical evidences were such as were compatible with leprosy in a comparatively early stage, viz., some two years duration.

Dr. T. C. Fox remarked that "it is a well-known fact that in two-thirds of the cases of tubercular leprosy examined the glands become enlarged," and he would be glad to learn if the committee had found any cell deposits in the glands about the viscera, such as were described by Hanson as being characteristic of this form of disease.

Dr. Powell, in reply, said the committee had not noticed any such aggregations of cells. The pathological morbid appearances were those of leprosy in an early stage of advance, but so far as they went they were definitely marked. He would, however, direct attention afresh to the discovery of the cells mentioned by Dr. Fox.

Dr. Dyce Duckworth on a case of

MYXŒDEMA, OR UNIVERSAL DEGENERATION OF THE CONNECTIVE TISSUE OF THE BODY.

S—— M——, æt. 34, married for ten years, mother of three children, came to St. Bartholomew's Hospital in Nov., 1878, complaining of weakness and of failing health for two years previously. She first observed that her eyelids and face swelled; subsequently swelling was noticed generally about the body. Her voice had become altered and thick. A sister who accompanied the patient stated that her manner had become altered and her temper more sullen and irritable since her ailment began. Indeed, some of her friends believed, in consequence, that she had become intemperate in her habits. She was a well-grown woman, of large build, but had lost two stones in weight during the previous eighteen months. Her face was of peculiar aspect, and she wore a listless expression. The complexion was waxy, with some clear redness over the malar bones, and there were several moles about the chin and cheeks. The eyelids were puffy and œdematous, having the aspect so common in chronic forms of tubal nephritis. The hands were clumsy-looking and seemingly swollen about the backs, but no dints could be made in them. It was alleged that they felt numb and sleepy at times. There was no appreciable change in common sensibility, and pins could be readily picked up. On examination some general condition of xeroderma was found on the limbs more especially, but no ordinary œdema. The first impression in this case was that there was some form of chronic nephritis present which would explain both the physiognomical aspect and the obvious swellings. The urine was found to be quite void of albumen, of sp. gr. 1010, acid in reaction. The heart was natural. The tongue was clean, and protruded naturally. The uvula was observed to be swollen and œdematous-looking. Appetite good; bowels usually constipated. The case was now regarded as one of that peculiar form of disorder described so well, and termed by Dr. Ord as "myxœdema," and other like instances of the disease were recalled to memory which had not been satisfactorily diagnosticated. The family history afforded no clue to the nature of the case. The children were healthy with the exception of the youngest, which was very ricketty, (The patient was present at the meeting, and a water-colour drawing of the face was shown.) The treatment consisted mainly of steel and cod-liver oil. On subsequent examinations the disorder was found to be making progress. The thyroid gland could not be felt, and a fatty cushion was found in the left supra-clavicular fossa. The face became more waxy and puffy, and the voice more slow and snuffling. The urine never was albuminous. The patient's manner was more sullen and reserved, and she was shy and resentful of clinical examination. Dr. Ord saw this case six months ago, and confirmed the opinion formed respecting it. It added one more to a series which have been, and still are, receiving careful study, and about which no doubt as to their true nature can now be entertained. Occurring only, so far as known at present, in the persons of women about middle life, the varying symptoms appear to be due to a gradually-spreading mucoid degeneration of the inter-cellular tissue throughout the body, which thus shuts off full and prompt appreciation of peripheral and other nervous impressions. Dr. Duckworth promised to report further observations upon this case at a future time.

Immediately following the reading of Dr. Duckworth's notes,

Dr. Ord read some further observations on

MYXŒDEMA,

Of which the following is an abstract:—

The paper gave the history and morbid anatomy of a second fatal case of the disease first described by Sir William Gull as "a cretinoid condition supervening in women in adult life," and subsequently named by Dr. Ord "Myxœdema." The patient was a woman, æt. 52, married, the mother of five children. Her illness dated from her last confinement twelve years before. She had begun then to swell in the face and all over the body. As she gradually increased in size she had become lethargic, had difficulty in collecting her thoughts, had difficulty in walking, and in holding up her head. When she came under observation, fourteen days before death, she presented in a very marked degree the appearances described by Sir William Gull and Dr. Ord in previous papers. The whole body was swollen, giving her the aspect of a person suffering from renal disease. The skin was translucent, dry, and very rough, on all parts except the face. The eyelids were bulged, the lips, upper and lower, greatly swollen, the alæ nasi much thickened. Each cheek presented a sharply-limited pink flush; the hands were spade-like, expressionless, and, with other extremities, were blue, by reason of feebleness of circulation. She spoke slowly and painfully, with leathery nasal intonation. Her movements were slow, and she halted quiveringly in her gait, but had no true paralysis, ataxy, or

Digitized by Google

tremblings. The droop forward of the head, noticed in a previous extreme case, was remarkable, the pressure of the chin upon the neck actually interfering with deglutition. Her senses were essentially unimpaired, but her response was long in coming, her memory defective, and her thoughts slow. The urine was of average quantity, of rather less than average specific gravity, and contained a trace of albumen. The arteries were firm, and the heart enlarged, but weak. The thyroid body was small. Having received bad news immediately after her admission to St. Thomas's Hospital, she fell into a lethargy which deepened daily, with intervals of feeble delirium, till she died, on the fourteenth day. While under observation her temperature was very low; for twelve days the average was between 90 deg. and 92 deg., on the 13th 88 deg., on the last day 77 deg. At the post-mortem exsmination all tegumentary and surface parts of the body were found swollen; the thyroid body was reduced in size and form; the kidneys were very firm, not reduced in size, smooth on the surface, and not adherent to their capsules; the cortical portion was somewhat narrower in section than normal; the liver and spleen were too firm; the heart dilated and hypertrophied, weight 12½ ounces The microscope showed in all parts a great increase of connective tissue. The fibrillar element was more abundant and more defined than normal; the interstitial mucus yielding element was greatly increased in proportion and quantity; nuclei were larger and more numerous. This was best seen in the skin, the glandular organs, and in the coats of arteries. The connective tissue presented a strong resemblance to that of the umbilical cord, and suggested the idea of a retrograde degeneration. The encroachment of it on tissues and organs was apparently the cause of death. Five other cases, all in women between 30 and 50, all married, were compared. All had low temperature; all had nervous weakness and lessened sensations; two, very advanced, had delusions. Those two, had traces of albuminuria; the rest, less advanced, gave no indications of renal affection. The symptoms and appearances being altogether of the same character as those observed in previous cases, Dr. Ord maintained that they showed the disease under consideration to be a substantive disease, and that they justified the use of the term "myxœdema," as marking the cause of the symptoms, and of the fatal termination.

The discussion on the two papers was commenced by Dr. SAUNDERS, Professor of Pathology at Edinburgh. North of the Tweed, he said, cases of myxœdema were not altogether unknown. Within his own experience, extending over a great number of years, he had met three instances of the disease, the last occasion on which he had seen it having been three years ago. This ended fatally. The disease, he continued, is a well-characterised one, and can be readily differentiated. He did not, unfortunately, possess a complete record of the cases he had some time treated, since they had left his care before the termination, and hence also he had never had the fortune (if it might be termed so) to witness a post-mortem in any instance. To him they presented a mere clinical picture, but he felt certain that the symptomatology of the disease was in complete harmony with the appearances presented by those suffering from it. All the cases he had personal knowledge of had ended in death, but in one at least considerable improvement had taken place. He could wish that the prognosis were not so invariably unfavourable to the patient.

Dr. GOODHART, remarking that Dr. Ord had thrown out the suggestion that the lethargic condition of the patients might be due to the effect of mucoid connective tissue surrounding and padding the nerve endings, declared his inability to see how interference with the peripheral sense organs could materially affect the brain of an adult subject. That some such effect might follow the action of such a cause during development, he could at once see; and he considered the dulled perceptions of the patients might be dependant on a primary cerebral affection. The brain, he suggested, might become subject to a sclerotic disease at once sufficient to induce all the mental disturbance noticed in these cases.

Dr. DUCKWORTH thought nothing had been said in direct reference to his own paper. He could not but admit many points in his case were incompletely treated, but this arose from the difficulty he found in persuading his patient to become the subject of continuous observation. As opportunity occurred, however, he would report on the progress of the case.

Dr. ORD: The tendency to mental aberration in these cases had been indicated in Dr. Duckworth's paper, and was a point worthy of receiving the attention of psychological inquirers. Referring to Prof. Sanders' regret that there were no recorded histories of the children of myxœdematous parents, he said he could produce such a history. One of his patients, a lady who was under his care ten years ago, left a considerable family. Of that family, one boy, a painter, had so far succeeded in life as to hang three pictures in the last Academy exhibition; and recently, he had, during his summer holiday, seen two other sons, swimming about in vigorous health. None of these showed signs of inherited defects, physical or mental; neither did any one of the female children of the same parents. The eldest child of the family is now, he said, twenty-seven years old. Dr. Ord thanked Prof. Sanders for the corroboration he afforded him, and agreed that the prognosis of the disease is bad. The duration of the cases he had seen to the end averaged 10 to 12 years; concerning treatment but little could be added. No efficient resistants to the disease are known. We give iron, &c., &c., but still the disease lives on. To Dr. Goodhart he might reply that he believed increase of connective tissue did occur in the brain of his patients; but opinions would vary as to the actual nature of the changes and their seat. He had found the senses perfect, though slow, throughout the progress of his cases. *Per*ception seemed less to be interfered with than *re*ception, the latter faculty being admittedly slow, but this certainly did not indicate any injury of the central apparatus. This, however, might at length be reacted on by continued peripheral disease.

Dr. F. TAYLOR and Mr. H. G. HOWSE on

A CASE OF EMPYÆMA IN WHICH PORTIONS OF THE RIBS WERE EXCISED.

The patient was a child, æt. 6, who was admitted into the Evelina Hospital in January 1877, with a history of acute pleurisy eleven weeks previously. The left chest was shrunken, and dull on percussion posteriorly, with deficient breath sounds, and some crepitation at the base in front. The temperature was at first nearly normal, but after a time it fluctuated considerably, often rising in the evening to 130° F. As this continued, and the physical signs were confined to the base of the left chest, this was explored on April 16th, and pus was found. The chest was then incised, and about ten ounces of pus were discharged. Tubes were inserted, and the chest washed out daily. On May 20th a counter-opening had to be made, but by the end of June very little real progress had been made, as the sinuses rapidly closed, and thus the pus secreted was retained. On July 2, Mr. Howse made a T-shaped incision through the skin round the existing aperture, and after separating the periosteum, removed with the bone-forceps portions of the seventh, eighth, and ninth ribs. Each portion was about 1½ inch in length. The thickened pleura was then cut through from the sinus, and two drainage tubes were inserted. The immediate improvement was decided, but the wound rapidly filled up, and in a short time the sinus was reduced to a channel no bigger than it was previous to the operation. From this time nothing further was done by operation. The pus continued to be secreted, and its retention was quickly followed by hectic symptoms. Albuminuria was discovered in September, 1877, two months after the operation; anasarca developed later, and there was frequent diarrhœa, so that she sank from the internal complications in October, 1878. At the post-mortem examination, the empyema was found to occupy chiefly the posterior part of the chest, reaching from base to apex. The lung was airless, except at the apex. There was no tubercle. The sixth, seventh, and eighth ribs were united by bony bridges. The liver, kidneys, and intestines, were lardaceous, and there was recent acute peritonitis. The operation performed in this case permitted more falling in of the chest than would have otherwise taken place, but did not facilitate the drainage so much as was desired. This was due to the rapid development of granulations and bone, which took place after the operation, the opening being quickly reduced to a narrow sinus. In another case it would probably be advisable to remove the periosteal tissue much more freely, even if it necessitated also the removal of the thickened pleura. The large opening thus obtained would also allow more complete exploration of the smaller cavities, apparently distinct from the main cavity, such as were found in this case at the time of the operation.

Dr. DOUGLAS POWELL considered the case narrated too interesting to pass uncommented on. He gathered that the first reason for operating was the necessity of introducing a

Digitized by Google

larger drainage tube. At this moment, he had under his care in Middlesex Hospital, a case in which something must soon be done of a similar nature. He would ask the authors if gouging out the rib to receive the tube would suffice, and if the pressure of the tube would sufficiently counteract the granulation growth? Also he would like to know if there was any special reason present to the operators for retaining the periosteum of the lowest rib removed?

Dr. TAYLOR replied that his first object was to obtain room for the discharge of pus. Whether a gouging operation would succeed must chiefly depend on the reparative power of the structures involved. In some instances the operation might be desirable. In his own case the child was not in a condition to encourage further operative procedure. In other cases this might not happen.

Mr. HOWSE thought the likelihood of succeeding with gouging extremely small. It was transcended as an operation by that described in the paper, which was, in reality, quite, even *too*, easy. He considered it an advantage to cut away much tissue. The success of the operation was hindered by their ignorance of many facts which became patent to them subsequently.

WEDNESDAY, OCTOBER 15, 1879.

THE RELATION OF THE STATE TO MEDICAL EDUCATION.—II.

THE aspirations of those who would legislate for the medical profession are naturally all in favour of keeping up the educational standard. They are self-conscious that the nature and amount of education which is required by licensing bodies, and which is recognised by the State as a qualification to enter on the practice of medicine, is but a small fraction of that which is necessary to make an astute, capable, and high-ranked physician, or even a practitioner of moderate social culture. It is universally felt by medical men that the teaching which was demanded of us as students was neither of the extent or the character necessary to give us confidence as practitioners in our daily combat with disease, or even in our daily association with our patients, and that our real education as practitioners has commenced only with our responsibilities towards those who consult us.

Feeling thus, many writers have clamoured for a great advance in the requirements of our licensing bodies—for a liberal preliminary education, even for a University Degree in Arts; for a thorough acquaintance, not only with the principles of medicine and surgery, and their practical application to the treatment of disease, but for an extended curriculum of education, and a searching examination in these subjects, and in Botany, Physics, Hygiene, Forensic Medicine, and all other subjects collateral to the study of physic. Such propositions, we say, are altogether Utopian; it would be impossible to realise them, and, *ultra crepidam* for any government to attempt their realisation. The skilled physician can never be made by such means, and there are many proofs within the experience of every one of us that a man may possess all these items of information, and yet be only semi-competent to treat disease, and wholly incompetent to satisfy his patient. His efficiency, in fact, is the offspring of faculties which can hardly be tested by examination, or greatly developed by curricula, and there could be no other test for it than his success in practice, and no examiner so competent as the patient whom he treats.

If it were possible to comply with the demands of authors who have urged that no person should be licensed to practice unless he were a man of liberal education, versed in science and in literature, and trained by long apprenticeship to the diagnosis and management of obscure ailments, we should in a great measure restrict the benefits of medical advice to the wealthy inhabitants of large towns, from whom the possessors of all these qualifications might hope to receive adequate repayment for the labour and cost incurred in acquiring this high degree of knowledge, and we would, practically, prohibit the exercise of the medical profession in poor places, or amongst sparse or needy populations, whose means hardly enable them to repay a practitioner for the short term of study, and the small outlay which is needed for the most humble, recognisable diploma.

Political economy also sets a limit to the standard of medical education, beyond which the theorist cannot stray. The duration, extent, and cost of an education must bear a reasonable proportion to the earning power which that education confers when it has been attained, and this earning power must depend more or less upon the special circumstances of the community in which the profession is exercised. If the number of experts in any art are insufficient to supply the demand for such experts, and if, in consequence, high prices can be obtained for the skill which they possess, then there will, necessarily, be an increased demand for the education essential for these experts, and it is open to us to counteract that demand and to raise the value of the expert's services by increasing the duration, difficulty, and expense of that education, and by raising its standard. If we can keep down the afflux of seekers for

Digitized by Google

admission to medical practice within moderate bounds, we can, at the same time, make the experts more skilful in their business. This principle, which is true of all trades, is only indirectly applicable to the exercise of mechanical arts, because for the exercise of these arts only a certain given amount of learning is required; more education is superfluous, less is insufficient, and, therefore, the over-supply of skilled mechanical labour cannot be met by imposing higher education, and can only be checked by the indirect action of the laws of supply and demand. But in the medical profession it is different. There is always, for a variety of concurrent social reasons, in our own and most civilised countries a supply of medicial practitioners more than equal to the demand for their services, and a constant tendency to over-stocking of the profession, and it is desirable to keep the demand and supply of medical practitioners as nearly as possible on a balance lest we should fall into the error, on the one hand, of leaving the public wants unsatisfied by restricting the supply, or on the other, of starving out the medical practitioners by encouraging an over supply. The equilibrium between demand and supply thus necessary ought properly to be maintained by a variation of the educational standard of the profession, and of the expense incident to the learning of it, and we cannot vary these factors to any great extent without disturbing the balance. We, therefore, repeat that the proposals of those writers who advocate a sudden and great raising of the educational standard of the medical profession are Utopian and impracticable, and I argue from these considerations that the State—being bound to consider the medical wants of the community rather than the aspirations of our profession, is compelled to fix the educational limit for entrance to medical practice—not at the point of high culture which we should desire that our physicians should possess, but at the level of reasonable competency to treat the ordinary run of prevalent diseases, without which it would be unsafe and improper to permit them to attempt to do so.

We hope we shall not be understood as undervaluing medical education, or making little of culture. We desire to do nothing of the sort, but simply to point out that our ideal of a physician or surgeon cannot be realised by such means, and that it is futile to attempt to bring the entire profession to such a standard, even if all other circumstances were favourable to such an attempt. We, therefore, seek for the regeneration of the profession, not in an extension of curricula, or a more lengthened course of study, but in a systematisation of the methods of teaching now existing, and an improvement in the method and the extent of the examinations which are the recognised test that sufficient knowledge has been acquired.

ODIUM MEDICUM.

We have some difficulty in believing that there are practitioners of the class complained of by numerous correspondents, or that the actions, attributed to physicians and consultants, really occur, Judging from letters we have received, and from the published correspondence in our medical journals, general practitioners evidently have not confidence in the majority of so-called consultants and a warfare is being waged between them, so that we do not seem to have improved since the time Molière wrote his comedies, and the *Odium Medicum* is as great a reproach as ever. It is not creditable to the profession; this feeling must be certainly against the interests of patients and the public. Amongst the lower and necessitous run of the profession, detraction of the abilities of other medical men may prevail, in order to procure a living, and impress the public with the excellence of the detractors; but it surely cannot exist amongst those who are placed by fortune above the wants of daily life. Detraction is the parent of supplantation, and detraction may be done in many ways. The artist in supplantation, we are told, often damns the general practitioner without uttering a word; this is done sometimes by the arching of the eyebrows, the pursing of the lips, by a shake of the head or a glance of the eye from the patient to the patient's friends, all speaking volumes. Such miserable artifices are to be condemned, and we hope this class is few.

It is painfully evident—especially from the pages of the *British Medical Journal*, in which there is more dirty linen publicly washed than in any of our medical journals—that the grievances and misunderstandings between local provincial practitioners are very great and widespread. We question whether much good is done to the profession, as a body, by the publication of such letters. There is a complaint, followed by a reply, from which it is clearly evident *that one of the writers must be lying*, and this appeal to the profession is utterly useless and futile. The public see the *British Medical Journal*, and the doctors' squabbles, so repeatedly published in it, cannot elevate their ideas of our profession. A committee selected from the general committee should first read and consider all these complaints, and before publication a copy of the letter of the aggrieved person should be sent to the accused, and if it be decided to publish the correspondence, both accusation and answer should appear together. This committee would form a court of honour, and all our dirty linen would be washed at home. Noted and proved offenders should be publicly placed in the stocks—and pilloried—in the journal.

We wish medical practitioners would lay to heart the advice of some of our old writers on medical quarrels. How very true are the following observations:—"Nothing has tended to injure the profession in the eyes of the public more than this intestine illiberality among its own professors. Unfortunately there are individuals who, caring only for their own interests, and totally in different to the honour and respectability of the faculty, give way to the baser passions of human nature.

"It is the duty, therefore, of influential members in the profession to discountenance such men and such conduct. There are sufficient sources of error, uncertainty, and doubt in the practice of medicine, without aggravating them by malicious insinuations and ungenerous comments, that too often destroy the peace of mind of suffering patients or surviving relatives, and the reputation of medical men, without a shadow of justice, or of benefit to any party. Patients and friends are but too often apt to indulge in reflections on the skill or success of their medical attendants, and it is the duty of all professional men immediately to check such querulous insinuations, instead of listening to them or fostering the spirit of dis-

Digitized by Google

content thus evinced. If medical men were to protect each other's reputation when clandestinely attacked, they would all reap the benefit, and they would rise higher in public estimation.

"But it will be said, 'are we to conceal ignorance, screen blunders, and sanction the errors of our brethren?' Who has constituted us their judges, we ask? Are we to listen to the *ex parte* statements of patients and friends, whose passions are enlisted in the cause of their fancied wrongs, and then pass judgment on hearing one side of the case? Such a decision would be most inequitable." We would ask our brethren to take these words to heart, and we hope the proprietors of the *British Medical Journal*, viz., the associates, will weigh our proposal, and not make the journal the vehicle of lowering the profession in public estimation.

THE DRUGGISTS AND THE DENTAL ACT.

The publication of the Dentist's Register is the first step towards the settlement of the claims of the various classes of persons who have been allowed to place their names on the list of registered dentists. From the correspondence which has appeared in the *Pharmaceutical Journal* and in the *Chemist and Druggist*, the principal contention seems to be concerning the application of the term *bonâ fide*. The chemists and druggists appear to maintain that having drawn a tooth at some time or another entitles any youth who may have assisted in a chemist and druggist's shop to claim a place on the Register. The dentists—at least those who have written on the subject, and who seem to be well informed on the matter—state that the term *bonâ fide* is especially designed to remove all ambiguity and to destroy all kinds of pretence whatever. It means good faith all round, no pretext is admitted under the term, and the mere extraction of a tooth no more entitles the operator to call himself a dentist than the gouging out of an eye constitutes him an oculist.

Many chemists and druggists assert that they have not registered with the view of going further in the practice of dentistry than the very partial extent to which they have hitherto ventured—viz., the extracting of teeth and occasionally the stopping of simple carious cavities; but being under the impression that in continuing this practice, unless registered, they would be infringing the law they have sought a place on the list. This is a mistaken view of the case. These men may continue to work on in their usual way, and we opine that the promoters of the Dentists Act never contemplated interfering except when the title of dentist or dental surgeon, or surgeon-dentist was wrongly assumed.

Another point which requires clearing up, and which will materially affect a large number of those who have placed their names on the new Register is, the expression, "in connection with pharmacy." When a man has to prove himself a pharmacist he has to appeal to his own particular register, and if his name be not there the Dentists' Register is a closed book to him, so far as he claims having practised in connection with pharmacy before the passing of the Act. This is the view hinted at by the promoters of the Dentists Act. These gentlemen have hitherto been very cautious in expressing their views, and by their extreme reticence they have laid themselves open on some occasions to severe criticism; but it must at the same time be admitted that they have carried their object so far with great determination, and have never been goaded into any rash assertion of their powers or intentions. From the few hints thrown out, it would seem that they have to a great extent anticipated the abuses from which their Register would be likely to suffer, and have made preparations accordingly. The organisation of the British Dental Association is, we understand, proceeding steadily, and people are being reminded that securing a false registration, or aiding or assisting in securing the same, is a misdemeanour which, according to the Dentists Act, is not punishable by a fine but by imprisonment, and that the placing of a name on the Register, and leaving it there until the Register has been published, does not secure the position of any one falsely registered, but only consummates the offence. Let us then hope that we may yet be able to congratulate the dentists on their scheme having succeeded beyond our expectations.

Notes on Current Topics.

The Sheffield Water Supply.

We trust we shall not weary our readers by so frequently harping on one string—defective sanitary arrangements—we have no choice. The *Press and Circular* has ever been the advocate of right, and the very motto we have adopted on our title-page points out the direction in which our efforts should be directed. The safety and well-being of the people must be our consideration, and for this reason we have so frequently had to be their champion. Need we recall our struggle for the good of Dublin, our persistent advocacy of sanitary reform, our repeated demands on behalf of the inhabitants, to gain for them protection from sewer-gas and polluted water, to secure efficient scavengering, the cleansing of the Liffey, inspection of lodging-houses, and all the other requirements which should be the rights of the citizens of a magnificent city. We need not linger on the history of the struggle, as in spite of the abuse showered by a certain section of the press on this journal, we have the satisfaction of knowing that our efforts have not been in vain, that the present Commission was largely due to our advocacy, and that the filth that disgraced Dublin will soon be a thing of the past.

We published in our issue of the 10th of September, under the heading, "An Incredible Story," another sanitary narrative, but the scene was laid in London, and with regret we have again to draw attention to a disgraceful sanitary grievance in a populous and wealthy Yorkshire town. We commend this story to the perusal of all interested in a pure water supply, and especially to the notice of the Central Committee, who are anxious about a national supply—independent of local authority. The facts are simply these. Three months since Dr. Whiteside Hime, the Medical Officer of Health, drew the atten-

Digitized by Google

tion of the Health Committee to the fact that the land around the water company's reservoirs had been sold for building purposes, pointing out the necessity of steps being taken to prevent the purity of the water supply of this large town being subjected to additional sources of danger from the habitations, sewers, &c., which were to be built down to within a few yards of the water's edge. In consequence of this report, the borough surveyor inspected these reservoirs, and quite concurred that the existing arrangements in connection with these three reservoirs were calculated to excite uneasiness. Since making that report, the reality of the dangers then apprehended have been too strongly corroborated. Immediately above the upper boundary wall of the Misfortune Dam, and about a dozen yards from the edge of the water, is a short road, formed on "made" ground. Under this road runs a sewer, formed of earthenware pipes, for the supply of some neighbouring house. Some of the pipes composing this sewer became, from some cause, disjointed and broken, and as a necessary consequence the sewage escaped and percolated through the ground down to the steep grassy slope above the water. Dr. Hime collected a sample of the foul black deposits from the bank about three or four yards from the edge of the water, and submitted to the borough analyst for examination. The two reports entirely agree that it was sewage. On learning this serious occurrence D. Hime called at the office of the water company, and explained to them how serious a matter it was, urging them to replace the defective sewer by an iron one, if it was necessary to have a sewer at all in that perilous position. However, the earthenware pipes have again been put in.

To these facts a Mr. H. B. Smith has attempted a reply, unique of its kind. In a letter to the town clerk Mr. Smith says: "In the absence of Mr. Ashton, your letter addressed to him and accompanied by a report by Dr. Hime, on the 18th of September, has been handed to me. In laying out for sale the land at Crookes Moor, the directors have been guided by what they believe to be excellent advice in all provisions and reservations necessary to ensure the purity of the water in their reservoirs, and they believe that there is no ground whatever for uneasiness on that subject. The road and sewer which Dr. Hime mentions are not the company's property, but belong to the representatives of Mr. George Hadfield, the late M.P. for this borough. The fracture of the pipes had been discovered and repaired before Dr. Hime's visit, but it does not appear that such fracture, whilst it existed, caused any damage or danger to the water of the reservoir. Not being their property the company have no power to substitute an iron line of pipes for those of earthenware now laid. It may perhaps be more Dr. Hime's *groundless apprehension* to be told that Misfortune Dam contains a large quantity of very fine fish which would not exist in sewage tainted water."

Dr. Hime has replied to this letter, further confirming his views and expressing the iniquitous nature of the drainage scheme which Mr. Smith attempts to defend.

We regret our space does not permit of re-printing Dr. Hime's letter. Sheffield possesses a health officer who is not afraid to state his views, and we consider that the inhabitants of Sheffield, who have to drink this water, should express their opinion unless they wish to be poisoned, and that they should support their able and independent medical officer of health in his praiseworthy efforts to secure for them unpolluted water.

The Small-Pox Epidemic at Birkenhead, 1877.

In some "Notes" on this epidemic by Dr. Francis Vacher, the very able Medical Officer of Health for Birkenhead, attention is drawn to the following points:—The initial cases being concealed cases; the especial prevalence of the disease among children and young persons; the especial fatality of the disease among the unvaccinated; the length of time between the first sense of illness and the appearance of the eruption; the length of the incubation period; and the position, sex, &c., of the affected patients. On the basis of the actual numbers of children and adults respectively attacked, corrected by the relative strength of the infant and adult populations, Dr. Vacher found that out of every 1,000 infants under twelve months, 16·6 were attacked with small-pox; that out of every 1,000 children between one and five years 5·3 were affected; that out of the same number between the ages of five and twenty, 1·9 were attacked; and out of every 1,000, twenty years old and upwards, 8·8 were attacked. Not a single person of sixty years old or upwards was attacked, although there were about 2,316 persons of this age living in Birkenhead at the time of the epidemic. The great liability of very young infants to this disease is shown by the fact that out of 32 unvaccinated children under one year old, 21 were but three months old or under, 8 being four weeks. Good proof is also given of the great fatality of the disease among the unvaccinated. The length of time between the first sense of illness and the appearance of the eruption has not as yet been accurately determined. Dr. Vacher found that of 524 cases, in 33·2 per cent. illness preceded the eruption by one day; in 31·5 per cent. by two days; in 19·0 per cent. by three days; in 7·6 per cent. by four days; in 2·6 per cent. by five days; and in 2·6 per cent. by a longer period. But in 3·2 per cent. the patient was either not ill before the appearance of the eruption, or ill only for a few hours before. With respect to a still more important question, "The length of the incubation period," Dr. Vacher says: "If I had been asked this question at the commencement of the epidemic, I should have answered that my experience and reading led me to believe that it was nearly always from twelve to fourteen days. In deference to the particulars now submitted, my answer would now be 'nearly always from twelve to twenty days.'" Lastly, an overwhelming majority of the sufferers in this epidemic were derived from the labouring class; and the remainder—six only excepted—from the artisan class.

The Parliamentary Reports on Irish Lunacy.

We think it well to note—in order to deprecate—the occurrence in the recent report of the Irish Inspectors of Lunacy of a paragraph which manifests their disposition to curtail, and, if possible, suspend altogether the annual

Digitized by Google

presentation to the public of the records of lunacy affairs in Ireland.

"The frequent recurrence of reports to Parliament," they say, "once annually on the state of a department limited in its extent, though important alike in a public and individual arpect, cannot afford much of novelty or of interest in detail, for in truth, no sooner almost are returns obtained in one year from local institutions, than like forms are transmitted to be filled up, for the succeeding. As regards the mental affected of all ages and types, the Poor-law Unions in 1878, twelve pages devoted to statistical figures do not expose a difference beyond one per cent. on the preceding year.

"In no branch of the public service is this circumstauce more observable than in the lunacy, and, perhaps, with less practical results, inasmuch as the responsible head of each asylum district affords annually to the residents in a detailad account of all matters, monetary and personal, of interest to the ratepayers. The enunciation of this doctrine may appear as pointing to a subterfuge from trouble, but it is not so intended, and the more particularly as the executive is at all times kept thoroughly cognisant by the inspectors of the working of district asylums.

"If in their office an annual record system were established, it appears to us that more comprehensive and practical deductions could be obtained, by taking the relative statistics of a series of years, and contrasting them with each other, than as at present by publishing details from twelvemonth to twelvemonth, which are fluctuating, and dependent in great measure on chance occurrences."

We altogether dissent from the tenour of these observations, and trust that they may not have any weight with the Government or with Parliament. The value of an annual report is not solely or indeed principally on the facts which it brings to light, but in the necessity which it imposes for a thorough yearly revision of the statistics and occurrences within the department. Moreover, in the case of the lunacy department, the inspectors should—in our opinion—be bound to render a yearly account of their stewardship, because their department is one over which the public ought to be unceasingly jealous of any lack of candour or any concealment. We do not for a moment admit that it would be a sufficient safeguard that "the executive" (which phrase we interpret to mean the top left hand pigeon-hole in the chief secretary's office) should be kept thoroughly cognisant of the working of district asylums. With respect, be it said, the public and the newspapers are much more important claimants for information on these subjects than "the executive." If the necessity of putting together an annual report once ceased, our experience of human nature and of public offices enables us to predict that the yearly overhaul of Irish lunacy affairs might fall into arrears and abeyance, and we might, perhaps, hear much less of the occasional "hitches" in asylum administration, the existence of which is now revealed to us in the annual report to the Lord-Lieutenant.

The New Irish Vaccination Act.

At the quarterly meeting of the Council of the Irish Medical Association, held at the Royal College of Surgeons on Tuesday, the 30th of September, the following resolution was unanimously adopted, viz. :—

Resolved—"That the Council of the Irish Medical Association, in acknowledgment of the able and valuable services rendered in Parliament by Mr. Charles H. Meldon, M.P., to the public and to the medical profession, with regard to the recent amendment of the Vaccination Laws of Ireland, hereby desire to express the deep sense of their gratitude to him; and to record their opinion that, owing in a great measure to his great tact, energy, and ability, a marked improvement has been effected in the law, by the passing of the 'Vaccination Amendment (Ireland) Act, 1879,' the provisions of which must prove very beneficial to the public interests.

"The Council at the same time desire to express their well considered and decided opinion, that until the provisions of the law now in force in England are fully extended to Ireland, it is futile to suppose that equal satisfactory results as regards protection of the public from small-pox, or mitigation of that disease and its dread consequences, can possibly be realised in Ireland. The Council, therefore, beg most earnestly to urge upon Mr. Meldon the advisability of continuing his able and active exertions to obtain for the public of Ireland the fullest provisions for their protection, not the least essential or important in effect of which is the extension to Ireland of the system of awards and inspection now in force in England; whereby not only would justice be extended to the Irish public vaccinators, but most beneficial results would accrue to the community of Ireland, of which they are as much in need, and to which they are as well entitled, as the people of England."

Peers as Touts.

A very objectionable method of touting for subscriptions has recently been adopted by some of the metropolitan charities. This, which consists in the broad-cast issue of lithographed letters bearing the signature of, and presumably written by, a titled personage, is not calculated to elevate the character of the institutions thus thrust upon public notice, in the eyes of those who are not irredeemable snobs. And it cannot be urged in defence of the proceeding even that it is necessary, for any ordinary appeal for public sympathy is usually sufficient to secure a measure of response adequate to the deserts of the soliciting institutions. The latest development of the nobleman-tout system is under the direction of Earl Cairns, Lord High Chancellor of Great Britain, who writes from "5 Cromwell Houses, S.W.," on paper bearing his coronet and monogram, which, it must be said, have descended very low down indeed, in being thus turned into a trumpery bait to secure subscriptions for Dr. Barnardo's Homes. What manner of people they are who are the patrons of the asylum on Stepney Causeway it might be interesting to know. Certain it must be that the sensible among them will be slow to respond to the new stimulus invented by the energetic manager of the institution; and unless we are very much mistaken, only disfavour will be created by the exhibition of a species of snobbery such as that we complain of. A while ago, we were appealed to in a similar manner by His Grace the Duke of Westminster, on behalf of the Metropolitan Cattle Trough Association. And again, we believe one, at least, of the regular hospitals, in an unwise moment, sought by a similar ruse to draw subscriptions from the pockets of such people as might be inexperienced enough in lithographic printing to be

Digitized by Google

deceived by the advertisement forwarded to them, and under the impression that they hold the autograph of a "real live lord," disburse an equivalent in cash for the honour conferred on them. The system is a contemptible one, and we can only express regret that there should be found in the ranks of the peerage men who think so uncharitably of the public as they must, to lend themselves willingly to the plan. Good wine needs no bush; and a meritorious charity needs no specious advertisement to ensure its due support.

Red Tapeism at the College of Physicians.

THE dilatory and halting progress of the Royal College of Physicians in the action taken by it with reference to the plague in Russia, redounds with only small credit to that ancient corporation. During the time when good could be effected only by instant energetic proceedings on their part, the members of the committee appointed to determine an immediate course of action, wasted the valuable time in aimless discussion and wandering dispute as to methods, the while the course of the disease was making ravaging inroads among the stricken populations. When after irretrievable loss of time a commission was appointed to make a special journey to the seat of the plague, and report on its nature and progress, it is not surprising that the gentlemen composing it found all their labour vain, the only evidences of the disease apparent on their arrival being the natural sequelæ of a continued epidemic. It is much to be regretted that the immensely valuable observations that might have been made by two such competent investigators as Dr. Payne and Surgeon-Major Colville, have been thus lost to medical science through the inertia of the College of Physicians. It is impossible to over-estimate the advantages that might well have followed had the visit been timed to occur during the irruption of the disease, both clinical and pathological; and we cannot resist the conviction that a spirit of greater animation is much to be desired in the deliberative councils of the institution in Pall Mall.

Social Science.

FOR anyone not a social scientist it is difficult to assign an excuse for the existence of the association which holds an annual congress for the discussion of so-called questions of social science, the proceedings of the Manchester meeting just concluded, show perhaps more strikingly than those of any recent occasion how almost useless the discussions must be as leading to any result of real benefit to society. Though there are to be found among the names of paper readers at, and members attending the Social Science Congress, it must nevertheless be admitted that the vast majority are either popularity hunters, or insatiable spouters. It would be difficult to determine which has the greater weight at the meeting of the association—desire for general progress, or a wish for individual advance; and with few exceptions it must be admitted that the discussions reported tend to favour the impression that the latter is the predominant motive. Excepting the discussion initiated by Lord Reay on "Land Tenure," there is little to be found in the indiscriminate talking which took place at Manchester which would repay a second perusal. The really important questions of a social kind that ought to be expected to claim the attention of social scientists seem to be perpetually shelved by them, and the discussions proper to their congress are left to be commenced and carried through in other quarters. Much assistance to hygyeists might be derived from the Social Science Association, but until the method and matter of its discussion undergo material change, it will be vain to expect it.

Sewer Gas.

THE advent of the cold weather brings with it many unpleasant experiences, but none perhaps more so than that of pedestrians along the streets when they are impregnated with the sewer-gas emanating from the open sewers occurring at intervals along the way. Especially noticeable is this nuisance in front of the General Post Office, but it is odorously clear also at almost any point where drains are placed. Serious injury may be, and doubtless often is caused by exhalation of poisonous gas from these places, and it is a fitting subject for medical officers of health to consider the necessity of so amending the existing drainage system as to remove the nuisance complained of. We know sufficiently well that the mere influence of a passing whiff of decomposing animal refuse is often adequate to determine the onset of disease in some constitutions; and it is, therefore, strongly probable that much real evil is to be attributed to the open street drains in large towns.

A Plea for the Lancet.

UNDER this heading, Dr. Buckler contributes a short article to the *Boston Medical and Surgical Journal*, in which he urges the advisability of a judicious employment of the lancet in cases of pneumonia and pleuro-pneumonia. He would not wish to supersede the restorative and tonic treatment, but only to combine with it a system of depletion; and in furtherance of his views he quotes instances where the employment of blood-letting has resulted in marked advantage to patients on whom but little effect had been produced by a course of treatment without the assistance of the lancet. The article is well worthy of perusal, the argument being ably sustained, and practically illustrated.

The Title of "Doctor."

AFTER all that has been said upon this subject, we have seen nothing more epigrammatic or more truthful than the observations of a correspondent of one of our contemporaries:—

The marrow of this bone of contention, he says, is simply vanity. The licentiate physician wishing to be accepted as a social and professional equal of a graduate of an university, assumes a title accorded to the latter by right of his degree, and the *mos et usus* of centuries.

Surely it is time the controversy should cease, and that the general practitioner should be content with his condition, and not try to appear bigger than he is by parading in borrowed plumes. The successful practitioner, of whatever titular grade, is quite satisfied to let every tub stand on its own bottom.

In fact, those who seek warrant for assuming the title of "Doctor" feel that the public believes in the higher attainments of an M.D., and, being unwilling to hoist themselves up to the level of a fully-graduated university M.D.,

Digitized by Google

by the expenditure of brains, time, and money, they want to pull down the distinction to their own level. It is as if all the captains of our army should ask to be allowed to call themselves "major," because, in their own opinion, they are quite as good as any major.

A New Escape for the Adulterators.

THE ingenuity of the adulteration fraternity and their lawyers is difficult to outwit. But recently a special Act of Parliament was passed to remedy a technical flaw in the law which they had discovered and used for their own safety. No sooner were they deprived of this safeguard than they start another point of law for their own protection in evil doing.

At Hanley, last week, a yeast dealer was charged before the magistrates with having sold an adulterated article. The sample analysed had been forwarded to the analyst at Hull by train, and it was contended that this was not a legal delivery, the Act requiring that samples should be personally delivered to the analyst or sent by registered post. On this ground the magistrates dismissed the case.

Prohibitions to Unlicensed Practice in the Colonies.

WE have already shown by quotations from French law, and by reference to statutes by which, in Great Britain, unqualified persons are forbiddden to practise pharmacy and other professions, that the toleration of medical quackery, which seems to be regarded as a fixed system amongst us, does not exist elsewhere, and that in communities just as enlightened and just as free as our own, uneducated and incompetent persons are forbidden to practise medicine for gain, and are punished for doing so. The latest recognition of the necessity for curbing quack practice comes from Canada, where we find a Bill introduced into the Assembly with consent of the Government, and likely to pass, which imposes restrictions and penalties not only—as in our own country—on false representation, but upon illegitimate practice for gain. The Bill is called,

An Act to further amend and consolidate the Acts relating to the Profession of Medicine and Surgery in the Province of Quebec.

It provides that from and after the passing of this Act, no person shall practise medicine, surgery, or midwifery, unless he shall have obtained a licence from the Provincial Medical Board, which is hereby authorised to issue such licence.

Any person not entitled to be registered in this province, who shall be convicted, upon the oath of one or more witnesses, of having practised medicine, surgery, or midwifery in the province of Quebec in contravention with the provisions of this Act, after the passing of this Act, for hire, gain, or hope of reward, shall incur a penalty of not less than twenty-five dollars, nor exceeding one hundred dollars.

A like penalty shall be incurred by every person assuming, after the passing of this Act, the title of doctor, physician, or surgeon, or any other name implying that he or she is legally authorised to practise medicine, surgery, or midwifery, if unable to establish the fact by legal proof, as required by the present Act, and the laws of the country.

Any person who, after the passing of this Act, in an advertisement published in a newspaper, or in written or printed circulars, or on business cards, or on signs, assumes a title, name, or designation of such a nature as to lead the public to suppose or believe that he or she is duly registered or qualified as a practitioner of medicine, surgery, or midwifery, or any of such branches of the medical profession, or any person who offers or gives his or her services as physician, surgeon, or accoucheur, for hire, gain, or hope of reward, if he or she be not duly authorised or registered in this province, shall, in each such case, incur a like penalty of not less than twenty-five, nor more than one hundred dollars.

Removal of left Pulmonary Lobe.

THE *New York Medical Journal* reports the case of an Indian boy, eight years of age, who was wounded by an arrow in the lower left thoracic region, between the sixth and seventh ribs. He removed the arrow himself, drawing with it a great portion of the lung. A physician who saw the case declared that he could do nothing for the boy, and that the projected tisssue was fat. Dr. Grinnell saw the patient twenty-four hours later; the extended lung had the appearance of a piece of liver, and gave off a strong and bad odour. After giving chloroform, a ligature was placed about the wound, and a piece of the protruding tissue was removed measuring four and one-half inches long by two and one-half inches wide. The portion of lung behind the ligature was washed with chloride of iron and returned to the thorax, and the wound sutured. There was some suppuration for a few days, and the ligature came away on the fifteenth day after the operation, giving exit to much pus, soon after which the boy was quite well.

The Topical Use of Ergot.

THE value of the local use of ergot is receiving endorsements from various quarters. It is particularly applicable in catarrhal diseases of the eye and throat. In chronic conjunctivitis it may be employed in the strength of gr. x. of the extract to ʒj. of water, a little glycerine being added to preserve the drug. In chronic pharyngitis, when the secretion is not very great, it makes an excellent ingredient of a gargle, or it may be used with tincture of iodine and applied with a probang. In cases of nasal catarrh, it may be applied by means of gelatine bougies. In using the ergot it should generally be combined with glycerine, as that agent both preserves it from decomposition, and keeps it longer in contact with the diseased surface.

The Medical Council Representation of the Queen's University.

WE understand that the Senate of the Queen's University in Ireland, which had its meeting last week, has unanimously resolved to call the attention of the Government to the fact that no provision now exists for the maintenance of the representation of the University in the Medical Council. The Queen's University has ceased to exist as a licensing body, and its Senate holds office only until the new Irish University is ready to grant degrees, which may be a month or a year. There is no provision in the Irish University Act for the election of a Medical Council representative, and inasmuch as the new institution is not mentioned in the schedule of the Medical Act, there is, of course, no authority for any representative of the Irish University to take part in its deliberations. These circumstances will be represented to the Lord-Lieutenant, and will, no doubt, be remedied in a short amending Act next

Digitized by Google

session—but meanwhile it is a question whether Sir Dominic Corrigan, who now represents the Queen's University, will not be *functus officio*, and disentitled from sitting in the Council before the omission to which we have referred can be remedied.

Lady Pharmaceutists.

By an almost unanimous vote of the Council of the English Pharmaceutical Society, the President — Mr. Sanford—alone dissenting, it was decided on the 1st of the month that two ladies—Miss Clarke and Miss Minshull —should be received as members of the Society. The permission given for the reception of these ladies was reversed on a former occasion by a small majority, on a vote of the members of the society at large, but it is anticipated that the next vote will be the other way, and that henceforth pharmacy is open to the female sex. We certainly do not see why it should not be so. We have already deprecated their exclusion from the medical profession by any special regulation, while at the same time we expressed our firm conviction that, as a rule, ladies are in all respects unsuited for anatomical and surgical study or practice. We do not, however, see their incapacity for dispensing medicines, and we therefore claim their right to a fair stage and no favour.

Surgeon-Major Reynolds, V.C.

We learn that the "Club" of the Royal College of Surgeons in Ireland, which consists of the present and past Presidents, Examiners, Professors, and Councillors of the College, hope at their annual dinner, which will shortly take place, to receive as their guest Surgeon-Major Reynolds, V.C., the hero of Rorke's Drift, who will visit Dublin next week. Surgeon-Major Reynolds is brother-in-law to Dr. Frank Davys, one of the Examiners of the College, and Coroner for the county, and it is most fitting that the College and its President should take the earliest occasion to recognise publicly their appreciation of his great gallantry.

The Anatomical Chair of Trinity College, Dublin.

The election of a Professor of Anatomy and Surgery in the University of Dublin, which takes place each seven years, was fixed for yesterday (Tuesday), too late for its result to be noticed in these columns. Dr. Benjamin G. M'Dowel, the present holder of the Chair, did not seek re-election. The appointment is worth about £800 a year, and carries with it, under the School of Physic Act, a surgeoncy to Sir Patrick Dun's Hospital. Three candidates have sent in applications for the Professorship, viz., Dr. Alexander Macalister, the Professor of Comparative Anatomy and Zoology, created by the Board in 1872; Dr. E. W. Collins, Surgeon to Jervis Street Hospital, and Senior Demonstrator of Anatomy in Trinity College; and Dr. Reuben J. Harvey, Lecturer on Physiology in the Carmichael College of Medicine and Surgery, and Assistant Physician to the House of Industry Hospitals.

The Difference between a Chemist and a Doctor.

We observe that the Chemists and Druggists' Trade Association has taken up the prosecution of unlicensed poison vendors, which duty had been hitherto performed by the English Pharmaceutical Society, with insufficient zeal. The Trade Association successfully prosecuted three persons for not having fully labelled the poisons which they had sold; and we are told that "These cases will serve to bring before the minds of magistrates the fact that the provisions of the Pharmacy Act for the safety of the public are being systematically disregarded by a great number of persons throughout the country trading as oil and colour merchants, grocers, drysalters, and patent medicine dealers. A great number of the poisons contained in the schedule to the Act are thus supplied to the public without bearing any of those precautionary protections against accident or misuse which the Legislature has indicated to be necessary." Far be it from us to discourage the enforcement of the law against unqualified poison sellers. May we not, however, claim our right to apply "like cause like rule" to the prosecution of unlicensed poison prescribers? The licensed pharmaceutist is armed with a law to stop the practice of pharmacy by quacks and druggist-grocers, and he does not allow anyone to plead that the public has a right to get its prescriptions made up where it pleases, or that a druggist-grocer has acquired a vested right in dispensing poisons by long years of usage. But he cannot recognise the same right in anyone else to put an end to unlicensed prescribing by himself, or by the avowed quack in the next street. It is strictly correct—according to his view —to compel the sick man to go to a qualified dispenser for his medicine, and to lock up in jail a trader who mixes the sick man's physic without having learned how to do so; but it is, nevertheless, he considers a monstrous invasion of the liberty of the subject, and an outrage upon the rights of free trading, if we seek to compel the same sick man to go to a qualified doctor for advice, or if we forbid a druggist to prescribe for him without having learned how to do so. Verily this is a verification of the recognised legal principle, that "one man may steal a horse, while another may not look over the hedge."

Widows and Orphans of Medical Men.

A Quarterly Court of the Directors of the Society for the Relief of Widows and Orphans of Medical Men was held on Wednesday last in the rooms of the Royal Medico-Chirurgical Society. The chair was taken by the President, Sir George Burrows, Bart., and the meeting was well attended, the change of hour from eight to five o'clock evidently suiting the convenience of the directors. Applications for grants were received from 58 widows, 12 orphans, and 3 orphans on the Copeland Fund. A sum of £1,250 was recommended to be granted at the next meeting. The expenses of the quarter amounted to £36. The Treasurer stating that the funds would allow of a donation at Christmas to each widow and orphan now receiving assistance, it was resolved that the same amount be presented this Christmas as upon the last occasion. The deaths of two widows were announced, and two orphans had become ineligible. One member was elected

Digitized by Google

and the death of one reported. The consideration of the question of extending the area of the benefits of the Society was adjourned to the next meeting.

The Health of Dublin.

THE deaths registered in the Dublin District during the week ending the 4th October, represent an annual mortality of 25·6 in every 1,000 of the population.

In 20 large English towns (inclusive of London, in which the rate was 19·0) the death-rate averaged 19·9 per 1,009 persons living; in Glasgow the rate was 15·6; and in Edinburgh, 17·5.

Twenty-seven deaths from zymotic diseases were registered, being 6 under the average number in the corresponding week of the last ten years: they comprise 5 from small-pox, 7 from scarlatina, 3 from croup, 1 from whooping-cough, 2 from fever (1 typhus and 1 typhoid), 5 from diarrhœa, &c.

The deaths from small-pox, all of which occurred in South City Districts, are 1 under the average number for the preceding 5 weeks, and 4 less than in the week ending 27th ultimo. The new cases of this disease admitted into the Dublin hospitals also show a decline, the number for the week being 17, or 11 less than in the previous week, and 25 under the admissions in the week ending 20th September. Twenty-four patients were discharged during the week, 4 died, and 69 remained under treatment on Saturday last, being 11 less than the number in hospital at the close of the previous week.

Nineteen cases of scarlatina were admitted into the principal Dublin hospitals last week, against 6 in the preceding week. There were not many cases of fever or of pneumonia admitted into those institutions during the week.

The Professorship of Medicine in Galway.

FOR the Chair, vacated by Dr. Colohan, senior, the vacancy of which we alluded to last week, we hear of the following local candidates, in addition to Dr. Rice, whose name we have already mentioned—Dr. Lynham, Dr. Walsh, Dr. Maguire, of Cong, Dr. Brodie, Dr. Keyes, Dr. Nolan, and Dr. Colohan, junior. There are, we believe, many others from Dublin and elsewhere, whose names have not reached us.

THE *Times* obituary records the decease of two medical men of some note—Professor Mohr, of Bonn University, and Dr. Seng, of Vienna, the former aged 72, and the latter 80. Professor Mohr, like his father, was originally an apothecary at Coblenz; in 1864 he was attached to the Bonn University; and some of his works on chemistry, geology, and physics have been considered worthy of translation into foreign languages. His activity was inexhaustible, and on his death-bed he dictated scientific treatises. Ignaz Seng, the son of a German, who on the outbreak of the first revolution left Paris for Vienna and entered the army, was a pupil of the surgeon Mozart, nephew of the composer, and he had many tales to tell of the Great Napoleon, Beethoven, and other famous men with whom he had come in contact.

THE receipts of the Hospital Saturday Fund up to date are represented to be £4,700.

YELLOW fever is gradually abating at Memphis, United States; there were but 22 deaths from it last week.

AMONGST the wounded in the battle last week before Cabul was Surgeon Duncan "dangerously." There are three of this name in the Army, and as no initials are given, we are unable to chronicle more definite information.

THE first meeting of the session of the Society of Medical Officers of Health will be held at 1 Adam Street, Adelphi, on Friday, October 17th, at eight p.m., when an inaugural address will be delivered by the President, Dr. 1. S. Bristowe.

WE are requested by the Committee of the National Orthopædic Hospital, 7 Adelaide Road, Dublin, to state that our recent observations as to the advertising of a Dublin orthopædic institution, did not refer to it, and that a recent advertisement in a Dublin paper, inserted on behalf of a patient of the institution, was not published with their knowledge or consent, and would not have been permitted if it were anticipated.

THE rates of mortality per 1,000 last week in the principal large towns of the United Kingdom were—Portsmouth 15, Leicester 15, Leeds 16, Nottingham 16, Brighton 16, Oldham 17, Sunderland 18, London 19, Sheffield 19, Birmingham 19, Bristol 19, Wolverhampton 19, Newcastle-upon-Tyne 21, Norwich 22, Hull 22, Plymouth 22, Bradford 24, and the highest rate 26 in Dublin, Manchester, Salford, and Liverpool.

IN the principal foreign cities the rates of mortality, according to the most recent weekly returns, were—in Calcutta 24, Bombay 36, Madras 34; Paris 25; Geneva 20; Brussels 24; Amsterdam 21, Rotterdam 20; The Hague 21; Copenhagen 27; Stockholm 16; Christiania 14; St. Petersburgh 33; Berlin 27, Hamburg 26, Dresden 30, Breslau 32, Munich 37, Vienna 23, Buda-Pesth 34; Rome 30, Naples 26, Turin 26; Alexandria 40 and New York 25, per 1,000 of the population. In Paris 20 deaths were referred to small-pox (against 6 and 16 in the two previous weeks), and 28 to typhoid fever.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

ANDERSON'S COLLEGE.—LECTURESHIP ON AURAL SURGERY.—The contest for this lectureship is being pushed with much vigour. The candidates are three well-known aurists, Drs. A. D. Stewart, Barr, and Kirk. Dr. Kirk, however, professes the throat in addition to the ear, but limits the latter field of operation to the orifices of the Eustachian tubes, and the immediately circumjacent parts. All the three candidates have undergone the requisite period of probation on the Continent; have sat under the

Digitized by Google

Limes, and paraded the Ringstrasse. As a matter of course the trinity of aural theology, "the late James Hinton, of London, Weber-Liel, of Berlin, and Professor Politzer, of Vienna," must be trotted out in solemn show. The respectable "philosophers," and other managers of the institution will have much difficulty, no doubt, in arriving at conclusions as to the respective merits of the candidates, seeing that aural operations amount to barely three, viz., Eustachian Catheterism, Puncture of the Membrana Tympani, and the Pneumatic Aspiration of Guineas by a Politzer Air-Pump. For the guidance of the managers we may state that the late Mr. Syme, if we mistake not, scientific made the following classification of aural diseases :—(*a*) Diseases of the ear which every person can cure. (*b*) Diseases of the ear which no person can cure. A new scientifical aural field has been discovered since Mr. Syme's time, viz., the relationship of aural disease to life assurance; though we fear the motives which led to the discovery are not particularly alien from those whereby the Romish Church discovered the El Dorado of Purgatory. We cordially sympathise with the managers in the difficult duty which falls so soon to be performed by them.

CAMBUSLANG.—SCARLET FEVER AND HOSPITAL ACCOMMODATION.—Scarlet fever has just appeared in Cambuslang, and several grown up persons have succumbed to the disease, which is confined, however, to one portion of the village, reported to be in a bad sanitary condition. The local authority of the parish have just agreed to erect a hospital for the treatment of epidemic disease, and Mr. A. Lindsay Miller, architect, has prepared plans for submission to the board of supervision. A committee has also been appointed to select a suitable site for the proposed erection.

GLASGOW MORTALITY.—The deaths in Glasgow for the week ending the 4th inst., were at the rate of 16 per 1,000 per annum, against the same figure in the preceding week, and 21, 22, and 22 in the corresponding periods of 1876, 1877, and 1878.

HOSPITAL SUNDAY IN AYR.—The first Sunday in May is henceforth to be Hospital Sunday in Ayr, the most of the ministers in town having agreed to ask their congregations on that day to give a collection to the hospital fund.

REGISTRAR-GENERAL'S RETURNS.—The weekly returns of births, deaths, and marriages in the eight principal towns of Scotland for the week ending Saturday, October 4th, says :—The death-rate in the eight principal towns during the week ending with Saturday, the 4th October, 1879, was 16·5 per 1,000 of estimated population. This rate is 3·7 under that for the corresponding week of last year, but 0·7 above that for the previous week of the present year. The lowest mortality was recorded in Aberdeen, viz., 12·7; and the highest in Paisley, viz., 22·3. The mortality from the seven most familiar zymotic diseases was rather under that for the preceding week, being at the rate of 2.5 per 1,000. Diarrhœa was the most prevalent of these diseases. Acute diseases of the chest caused 76 deaths, or 14 more than the number recorded during the previous week. A marked increase is observed in Dundee, while in Glasgow the number for the last week remains the same.

GLASGOW MATERNITY HOSPITAL.—A meeting of the subscribers to this charity was held in the Religious Institution Rooms on the 9th inst., Mr. R. Grant in the chair. The chairman read a statement drawn up by the directors, in which it was stated that they had long been of opinion that the present buildings were unsuited to the requirements of the hospital. A sub-committee had been appointed in November last to consider the matter, and after some time an architect prepared plans for a new hospital on the site of the present one. It was resolved to go on with this new building at a cost of £6,000.

HEALTH OF EDINBURGH.—The deaths in Edinburgh for the week ending the 4th inst. were 68, giving a rate of mortality equal to 16 per 1,000. The zymotic mortality was unusually low, and consisted of three cases of whooping-cough, one of which occurred in the New Town. There were only four deaths from diarrhœa, and two of these were under five years. Of the 137 births, 9 were illegitimate.

DUNOON CONVALESCENT HOME.—A meeting of subscribers to this institution was held in Glasgow on the 6th inst. From the report submitted it appears that no fewer than 2,337 patients have shared the advantages of the homes during the year, being an excess of 399 over the number admitted last year. Of these 2,059 were perfectly restored, and only 129 did not improve, one having died. Since the homes were established 14,584 convalescents have been admitted, and the proportion of the perfectly restored has been steadily maintained. The homes seem to have benefited from the fall in prices which have taken place during the year, for the weekly cost for each patient for maintenance has only been 5s. 10d., against 6s. 5d. last year.

SURGEONS' HALL, EDINBURGH.—At a meeting of the lecturers of Surgeons' Hall, Edinburgh, held on the 7th inst., the following appointments were made :—Dr. Affleck, Assistant-Physician to the Royal Infirmary, was unanimously appointed to the Lectureship on Practice of Medicine, vacant by the resignation of Dr. Muirhead; and Dr. Buist, Physician to the Western Dispensary, was also unanimously appointed Lecturer on Pathology, in succession to Dr. Wyllie.

BANFF.—Dr, Barclay has been appointed by the parochial board (as local authority under the Public Health Act), as medical officer, in succession to the late Dr. Clayton.

NOT TO BE DONE.—The following story is current in Scotch medical circles at present :—A pushing specialist being consulted by a well-to-do individual who lived in a house which he owned himself, was advised that a serious operation should be performed, and that the fee would be considerable. At first an exorbitant sum was demanded, and refused on the ground of straightened circumstances. This was halved, and further diminished, with the same disappointing result on the part of the patient. At last a happy solution of the difficulty appeared to the specialist, "Oh! put a bond on your house!" Patient made tracks!

THE CRICHTON ASYLUM, DUMFRIES.—By the retirement of Dr. Gilchrist from the Crichton Asylum, Dumfries, which comes into effect on the 11th November, prox., an important and valuable appointment will be thrown open to the psychological branch of the medical profession. It is understood that the board of direction is now occupied in making inquiries for a suitable successor.

ACTION FOR DAMAGES AGAINST A GLASGOW DOCTOR.—In the Glasgow Sheriff Court an action has been raised at the instance of James Pringle Rodgers, commercial traveller, against James Simpson Cumming, M.D. and Surgeon, St Vincent Street, to recover the sum of £500 as damages. The pursuer sets forth in his condescendence that on the 15th of February last, while leaving his own house he fell and broke his leg. The defendant was called in the next day, and he stated that it was a good and clean break, and would be all right in four or five weeks, but as pursuer's leg was then so much swollen and inflamed he could not set it. On the 22nd of February defendant set pursuer's leg with one splint, and did not again visit him till the 1st of March. From the 1st to the 8th of March defendant called upon the pursuer about three times, and although he promised to call again he did not do so; and after waiting about five weeks, pursuer called in another medical man. Pursuer alleges that, in consequence of the maltreatment and gross culpable neglect of the leg by the defender, he had suffered, and continues to suffer, in his bodily health, and has since been unable to follow active employment, and will not be able to do so for years. The defender stated that on being called to see pursuer he ordered the usual remedies to reduce the swelling, and promised to call again in a few days. He understood, and was led to believe, that the pursuer was in destitute circumstances, and was unable to employ medical assistance in the usual way. The defender further stated that he was not employed by the pursuer, and did not undertake any employment in the matter. What he did in coming originally, and in his subsequent visits, was done from motives of charity towards the pursuer. He recommended the pursuer's removal to the infirmary for more convenient treatment, but this pursuer objected to. The defender admits that a few days

Digitized by Google

after the accident he set the pursuer's leg; and explains that in such cases it is not necessary to do more than call occasionally, and he called as often as the exigencies of the case required. The defender called at the pursuer's house at least twice after the date of his last examination, and failed to obtain admittance. Assuming that his services were no longer required he ceased attending. He explains that if the pursuer had given the leg proper treatment after having been set by him, he would have recovered in a satisfactory way. The defender had been informed, and believed, that the pursuer had kept moving about in bed, and that his limb not having been kept still, if anything has gone wrong it is the pursuer's own fault. The defender has been informed that during his confinement to bed, pursuer had been indulging to a considerable extent in intoxicating liquors, the taking of which had most injuriously prejudiced his recovery. The case has been continued for proof.

Literary Notes and Gossip.

THE publishing season of 1879 cannot so far be said to be a productive one, at least in medical books. Not one large or important English book has yet reached us, and even of smaller manuals and treatises fewer than usual have found their way to our table. True, there are a few new editions of existing works, such as Michael Foster's "Physiology," Bell's "Manual of Surgical Operations," &c., announced or have just appeared, but there is a decided absence of anything new or startling from any of the recognised publishing houses, still less gossip among authors as to works in preparation. It is the fashion to put everything down to the depression in trades. More students have entered the medical schools this session because of the "depression in trade," but trade depression should argue to the contrary for literary work, as deficiency in fees, means an overplus of time, and this latter an excitant to enterprise in other directions.

* * *

THERE is probably no wider field for enterprise, certainly not one in which fortunes are sooner made or lost, than in literature. As a striking instance of this, may be mentioned the *Daily Telegraph*, which claims "the largest circulation in the world." Started about a quarter of a century ago by Colonel Sleigh, that gentleman soon lost his all in the venture, and was glad to hand over the copyright to a printer of the name of Levy to settle a small claim. Mr. Levy borrowed £1,500, still it did not succeed. Upon the repeal of the paper duty, Mr. Lionel Levy, a brother residing in France, came over and assisted in negotiating a share in the paper for a very small sum, and soon after it began to pay its expenses. This same Mr. Lionel Levy has just died, leaving two millions sterling, amassed during these few years in a literary venture.

* * *

A LITERARY wit of scientific tendencies is rather hard upon Professor Tyndall, and thinks that the Dean of Westminster when he married him a short time since missed his opportunity. He is of opinion that when the Dean put the familiar query in the marriage service it should have run thus: Do you take this anthropoid to be your co-ordinate, to love with your nerve centres, to cherish with your whole cellular tissue, until a final molecular disturbance shall resolve its organism into its primitive atoms? The learned professor would probably have thought twice before answering, I will!

* * *

THE half-yearly volume of the *Journal of Psychological Medicine* to-hand, keeps up its reputation for sound work in its special line, and is, probably, well-supported, as it deserves to be by those for whom it is designed. The article on "The Education of Girls, connected with Growth and Physical Development," by Dr. Nathan Allen, of New York, shows evidence of careful study; and that on "Mental Responsibility and the Diagnosis of Insanity in Criminal Cases," by Dr. E. C. Mann, will well repay perusal. There is also more than the usual amount of editorial work in the volume, which should have an especial interest to proprietors of private lunatic asylums, whose cause it espoused in face of their detractors, with the self-evident conviction of the writer that *magna est veritas, et prævalebit.*

DR. A. W. FOOTE has published an exhaustive review in the October number of the *Dublin Journal of the Medical Sciences*, of Fleming's work on "Hydrophobia," and our report on the same subject. Strange to say, he has also criticised the small treatise by Dr. McNeil, we reviewed in the *Medical Press and Circular* of September 17th, 1879. We wonder how Dr. Foote omitted one important part of a critic's duty. He does not seem to have detected either source from which Dr. McNeil drew his information.

* * *

THE *Quarterly Journal of Inebriety* for October maintains its character. We hope it meets the support it deserves. The temperance party in England is a large one, and a high class journal has long been a *desideratum*.

* * *

As we are on the subject, we would like to ask how many thousands of pounds has been spent on the *Alliance News?* Would some statistician add up the weekly list of contributions received, and let us know the sum total?

* * *

DR. NORMAN KERR at the end of his paper on the "Temperance Movement," gave a list of books. Why did he omit the most important work, Miller's "Alcohol: its Place and Power." The Scottish Temperance League published the work in 1866. Thirty-six thousand copies are said to have been sold. In "Alcohol: its Place and Power," the profession will find a guide, philosopher, and friend. We need not say another word, *verbum sap.*

* * *

OF the magazines that have reached us during the past month, the majority are up to their usual standard of excellence. *Countries of the World*, like its subject seems to have no end, nevertheless it is a good publication, and when completed, will form a cyclopædia fit for any library. We would also specially commend *Greenhouse Favourites*, a work now appearing in monthly parts, for its beautifully coloured plates, and popularly written text; to those of our readers who are fortunate enough to possess the luxury of a greenhouse, no better guide will be found. We must also not omit to mention the *Boy's Own Paper*, a magazine of its kind without an equal. This extremely useful publication, was started less than twelve months since by the Society for Promoting Christian Knowledge in order to stem the tide of pernicious literature for boys; its editor, Dr. James Macaulay, being a member of the medical profession. Such has been its success that it has now reached the enormous circulation of more than a quarter of a million of copies. We have received the first volume, and can honestly say that nothing has been published which we would place in the hands of youth with greater pleasure.

* * *

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last list, August 6th, "Clinical Medicine," by Austin Flint, M.D. "Vocal Physiology and Hygiene," by Gordon Holmes, L.R.C.P. "Hygiene and Public Health," by A. H. Buck, M.D. "On Colour-Blindness, by B. J. Jeffries, M.D. "Ocular Therapeutics," by L. De. Wecker. Translated by Dr. L. Forbes. "On Eye-ball Tension," by W. Spencer Watson," F.R.C.S. "Chemical Notes and Equations," by R. Milne Murray, M.B. "The Mechanism of Man," by E. W. Cox, vol. i., third edition. "Tunstall on the Bath Waters," edited by Dr. Carter. "Essays in Ophthalmology," by G. E. Walker, F.R.C.S. "A Manual of the Operations of Surgery," by J. Bell, F.R.C.S. "Health Lectures for the People," delivered in Manchester. "Botanical Note-book," by E. M. Holmes, F.L.S. "Deaths in Childbed," by Æneas Munro, M.D. "Klein's Atlas of Histology," part vii. "Godlee's Atlas of Human Anatomy," part x. "On Contraction of the Fingers," by W. Adams, F.R.C.S. "San Remo," by A. Hill Hassall, M.D. "Manual of Practical Anatomy, by J. Cossar-Ewart, M.D. "The Dentists' Register," 1879 (official). "Clinical Lectures and Essays," by Sir James Paget Bart, F.R.S., second edition. "A Treatise on Cancer," by R. Mitchell, M.R.C.S. "The Pocket-Gray or Anatomists' *Vade Mecum.*" "The Female Organs of Generation, part iii., of Human Anatomy and Physiology," by Dr. Palfrey. "Proceedings of the Medical Society of London," vol. iv.

* * *

PAMPHLETS.—The following have been received since the publication of our last list, August 6th. "Medical Educa-

Digitized by Google

tion and Medical Organisation," by Walter Rivington, F.R.C.S. "On Acute Bronchitis," by D. J. Hamilton, M.B. "On the Process of Healing," by D. J. Hamilton, M.B. "On the Diseases of Animals which do not necessarily render them unfit for the Food of Man," by Francis Vacher, F.C.S. "The Metric System," by J. F. Baldwin, M.B. "Longevity, its Limits and Frequency," by W. J. Thorns, L.S.A. "English County Asylums," by the Hon. Francis Scott. "Natural Mineral Waters, their Properties and Uses." "Report of the Sanitary Condition of Birkenhead for 1878." "Notes on the Epidemic of Small-pox at Birkenhead," by Francis Vacher. "Il Clima di Catania," by Dr. G. B. Ughetti.

* * *

In a certain locality, much frequented by tourists, the editor of a local newspaper had a room at the hotel. Being absent one night, the landlord put a stranger in his bed. The next morning the following lines were found in his room :—

I slept in an editor's bed last night,
And others may say what they please ;
I say there's one editor in the world
That certainly takes his ease.

When I thought of my humble cot away,
I could not suppress a sigh,
But thought as I rolled in the feathery nest,
How easy editors lie.

The editor, after some inquiries of the landlord, made the following addition :—

The chap whose form has rested here,
And left his copy behind,
For a bad impression should be locked up,
As the cut is most unkind.

Behold a proof of how he lies !
In the morning he went away,
And, like many who use an editor's sheet,
He had forgotten the bill to pay.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Mr. Baylis.—The Students' Number is almost out of print, and can now only be supplied by our publishers at double price.

Dr. Stretch Dowse.—The report will appear in an early number.

STATISTICS ON THE HYPODERMIC INJECTION OF MORPHIA.

Dr. H. H. Kane, of New York, who has for some time time past been collecting statistics on the hypodermic injection of morphia, writes us that he will consider it a favour if members of the profession in this country having had experience in the use of this drug will answer the following questions:—

1. What is your usual dose ?
2. Do you use it alone or with atropia ?
3. What is the largest amount you have ever given at one time ?
4. Have you had any inflammation or abscess at the point of puncture ?
9. Have you had any deaths or accidents thus produced ?
6. Do you know of any cases of the opium-habit from the use of this drug ?

In case of death, please give the results of the autopsy, if any was held. Any reference to journal or other literature on this subject will be thankfully received. All communications will be considered strictly confidential, the author's name not being used, unless permission to that effect is freely given. Address all communications to Dr. H. H. Kane, 366 Bleecker Street, New York.

Mr. J. C. Stirling, Crawley.—You will obtain the necessary information on addressing a letter to the Secretary of the Sanitary Institute, Spring Gardens, London, S.W.

MEDICAL ADVERTISEMENTS IN THE LAY PRESS.

The following letter is addressed to a medical contemporary :—

Sir,—With your permission I beg to call the attention of the profession to the system of medical institutions advertising for medical officers in the columns of the lay press side by side with those of cooks and butlers. When these advertisements are solely intended for the medical profession why not insert them in the medical journals ? In the Dublin papers almost daily there appear such advertisements in the same column as those of domestic servants. When it is considered that on the board of every medical institution there are some of our profession, it is surprising why they ignore their own representative journals and agree to order these advertisements to be inserted only in the lay papers. Although the Local Government Board for Ireland has a medical commissioner, still none of the Poor-law advertisements for medical officers are ever inserted in the medical journals.

Yours, &c.,
L.R.C.S.I.

[One of the chief reasons for the omission of the Irish Poor-law advertisements from the pages of medical journals is, that it is not desired by the guardians to secure any publicity for the vacant appointment. Not infrequently the election of the new officer is "squared" before the advertisement is published, often before the former officer resigns, and the guardians would, therefore, not advertise at all, but that they are obliged by law to do so. In a recent issue we called attention to a case in which the dispensary committee advertised an election and brought candidates from long distances, but held no election, and a fortnight afterwards appointed a young gentleman who could not possess the requisite qualification.]

FOREIGN DEGREES.

To the Editor of the Medical Press and Circular.

Sir,—I have read with interest your article on Foreign Degrees, and would like to draw the attention of your readers to the subject. The Brussels examination is held in English. Now I think this takes away from the merit of the degree very much. If a practitioner holds a foreign degree I naturally presume he knows the language of the country he was examined in. I imagine the following dialogue at a dinner party :—

Educated Host.—By-the-bye, Smith, you are an M.D. Giessen ; of course you speak German ?

Smith, M.D. Giessen.—No, the fact is I know nothing of German ; was examined in English.

Educated Host (*dubiously*).—Ha ! rather peculiar (*to himself*, I wonder who sold him his degree ?)

Or imagine the same about Brussels, and actually that any one should not know French in the present age.

Yours truly,
October, 1878. M.D., of nowhere.

To the Editor of the Medical Press and Circular.

Sir,—I think your remarks about Foreign Degrees will induce some of our English universities to follow suit, and all Englishmen have a chance of obtaining an M.D degree at home. Brussels has set an example which may soon be followed by other Continental Universities, so that the future number of M.D.s (foreign) will be innumerable, which no one would more regret than

Yours,
October, 1879. English.

Harveian Society of London.—On Thursday, Oct. 16, at 8½ p.m., Mr. Alderson, "A Case of Immense Enlargement of the Heart."—Dr. Fothergill, "The Immediate and Permanent Treatment of Disease."

Hunterian Society.—This evening (Wednesday), at 7½ o'clock, Council Meeting.—8 o'clock, Short Address by the President, Dr. J. Braxton Hicks.—Mr. Hutchinson, "On the Relationship between Locomotor Ataxy and Syphilis."

VACANCIES.

Ardee Union, Castlebellingham Dispensary.—Medical Officer. Salary, £100, with fees, and £15 as Sanitary Officer. Election, Oct. 24.

Castlerea Union, Castlerea Dispensary.—Medical Officer. Salary, £100, with fees, and £25 as Medical Officer of Health. Election, Nov. 1.

Dore Union, Hereford.—Medical Officer for the Workhouse and District. Salary, £80, with an additional allowance for the duties of Health Officer. Applications to the Clerk at the Union Offices before Oct. 20.

Great Northern Hospital, London.—House Surgeon. Salary, 60 gns., with board. Applications to the Secretary before Nov. 5.

Martley Union.—District Medical Officer. Salary, £50, with the usual extra fees. Applications to Mr. A. W. Knott, 14 Foregate Street, Worcester, before Oct. 30.

Queen's College, Belfast.—Professorship of Chemistry. Applications to the Under Secretary, Dublin Castle, before Oct. 18.

Royal Hospital for Diseases of the Chest.—House Physician. Salary, £80. Immediate application to the Secretary, City Road, London, E.C.

West Bromwich Hospital.—House Surgeon. Salary, £80, with board. Applications to the Hon. Sec. before Oct. 21.

West Sussex Infirmary.—House Surgeon. Salary, £80, with board, and £20 extra for duties as Secretary. Applications to the Secretary at the Infirmary, Chichester, before Oct. 25.

Births.

Mackintosh.—On Oct. 6, at 260 Clapham Road, S.W., the wife of Hy. Mackintosh, L.R.C.S.Ed., of a daughter.

Napper.—On Oct. 9, at Cranleigh, Surrey, the wife of A. Arthur Napper, M.R.C.S., of a son.

Nixon.—On Oct. 4, at 32 Upper Merrion Street, Dublin, the wife of C. J. Nixon, M.D., of a daughter.

Tellet.—On Sept. 30, at Ramsey, Isle of Man, the wife of Frederick S. Tellet, L.K.Q.C.P.I., L.R.C.S.I., of a daughter.

Deaths.

Campbell.—On Sept. 12, at Stoney Hill, Jamaica, Alex. B. Campbell, M.D.

Dowson.—On Oct. 8, at West Humble, Surrey, Ernest Dowson, M.D., of 117 Park Street, London, W., only son of J. Dowson, M.D., of Wimbledon, aged 47.

Greeves.—On Sept 20, at Clevedon House, Hammersmith, J. Greeves, L.S.A.L., aged 69.

Reid.—On Sept. 28, at Troon, Ayrshire, J. Litster Reid, L.R.C.P.Ed., aged 32.

Thompson.—On Oct. 2, at Gomersal, T. Young Thompson, M.R.C.S., aged 57.

IRISH POOR-LAW INTELLIGENCE.

IRISH MEDICAL ASSOCIATION.

Royal College of Surgeons,
Dublin, 30th August, 189.

RE THE NEW VACCINATION ACT.

(Continued from our last)

Section 5.—(*Verbatim.*) *Continued.*

THE principal change made by this section is that the certificate of a successful vaccination, performed by a medical practitioner other than the medical officer of the dispensary district, shall be forwarded to the registrar of births and deaths for the district WITHIN WHICH THE CHILD'S BIRTH WAS REGISTERED—hitherto such certificates were required to be forwarded to the registrar for the district in *which the vaccination was performed.* This alteration is very important, as it will facilitate the detection of defaulters, but in order that this may be done thoroughly every registrar of births should keep an index of the births registered, in which each entry should be marked off upon the vaccination being certified. The deaths of children who have died before three months of age being also marked off, as well as the cases of insusceptibility and those postponed on account of certified unfitness, the remainder would be the defaulters.

Although a merely voluntary duty, the Council advise the adoption of this method by all registrars of births as the most convenient, easy, and effectual one of detecting defaulters. It being hoped and expected that they will do their utmost to ensure that the provisions of the law are in every instance acted upon—early, efficient, and universal vaccination being essential for the public welfare.

Section 6 provides that the board of guardians shall pay to every medical officer for every person successfully vaccinated by him, within his dispensary district, the sum of TWO SHILLINGS."

For every successful vaccination or re-vaccination performed since the 15th August, 1879, the dispensary medical officers are entitled to claim two shillings instead of one shilling as formerly.

Section 7.—(*Verbhtim.*)

7. "Every person who prevents any dispensary medical officer from taking any child lymph, as provided by section four of this Act, shall be liable, on summary conviction, to pay a penalty not exceeding twenty shillings.

"The defendant in any proceedings under the Vaccination (Ireland) Acts may appear by any member of his family, or any other person authorised by him in this behalf.

"Where any parent or other person having the custody of a child fails to produce such child when required so to do by any summons under the said Acts, such parent or other person shall be liable, on summary conviction, to a penalty not exceeding twenty shillings.

"Every parent or person having the custody of a child who neglects to take such child or to cause it to be taken to be vaccinated, or after vaccination to be inspected, according to the provisions of the Vaccination (Ireland) Acts, and does not render a reasonable excuse for his neglect, shall be guilty of an offence, and be liable to be proceeded against in a summary manner, and upon conviction, shall be liable to a penalty not exceeding twenty shillings."

The maximum of each of the several penalties under this Act is *twenty shillings* in each instance—under the old Act *ten shillings* was the maximum penalty, and it was confined to default of vaccination within six months of birth, and neglect to bring the child for inspection on the eighth day after the operation.

Section 8.—(*Verbatim.*)

8. "Every medical officer, parent, or person, as the case shall require, who shall neglect to transmit any certificate required of him by the provisions of the Vaccination (Ireland) Acts, completely filled up and legibly written to the registrar within the time specified by the said Acts, and every medical officer who shall refuse to deliver the duplicate to the parent or other person, on request, or who shall refuse to fill up and sign the certificate of successful vaccination, shall be liable to pay upon a summary conviction a penalty not exceeding twenty shillings; and every person who shall wilfully sign a false certificate or duplicate under this Act shall be guilty of a misdemeanour, and punishable accordingly."

A certificate of successful vaccination is now required to be "*completely filled up and legibly written,*" and to be immediately transmitted to the registrar, under penalty of twenty shillings; heretofore such omission was punishable as a *misdemeanour*, which entails IMPRISONMENT, without the option of paying a fine instead; although that penalty was seldom, if ever, enforced, no right-minded or loyal subject can reasonably object to the change, which doubtless will not be required to be enforced more frequently than the much more severe penalty under the old Act. For a wilfully false certificate the penalty, though severe, can not be considered excessive. It will be observed that the several penalties are now made similar to those under the English Vaccination Act.

Section 9 provides that it shall not be necessary, in cases of prosecutions under thic Act, to *prove* that notice of the requirements of the law shall have been given to the defendant, nevertheless the usual notice must be given by the registrar of births. Heretofore it was essential to *prove* that the notice had been given, but henceforth every person is required to know that it is imperative to have every child born since the 15th August, 1879, vaccinated within three months of its birth.

Section 10.—(*Verbatim.*)

10. "The guardians of any union in Ireland may direct

Digitized by Google

proceedings to be instituted for the purpose of enforcing obedience to the provisions of the Vaccination (Ireland) Acts. The medical officer of any dispensary district who may be required by the guardians of the union to attend, and who shall attend at any such proceedings, shall, in addition to his actual expenses, be entitled to receive for his remuneration for such attendance such sum, not exceeding one guinea for each day upon which his attendance shall have been required and given, as the court before whom the proceedings are had shall certify; and as to such remuneration and expenses, and all other expenses incurred in the prosecution, if the court is of opinion that they should be allowed, the justice or one of the justices shall ascertain and certify the amount thereof to the guardians of the said union, set forth in Form C in the first schedule of this Act, and such amount shall be payable out of the poor rates of the union in which the neglect or default shall have arisen; and such proceedings on account of neglect to have a child vaccinated may be taken at any time during the continuance of the neglect."

It will be observed that the amount of remuneration—not exceeding one guinea a day—to be allowed to a medical officer for attending and giving evidence at a vaccination prosecution is stilt left to the discretion of the justices to certify or refuse; but it appears that the actual expenses incurred by the medical officer, if proved by him, are to be allowed by the justices.

The perpetuation of this very unsatisfactory arrangemegt as to remuneration for evidence at vaccination prosecutions, is much to be regretted, it having for many years past been perhaps the most fruitful source of discontent, as far as the medical officers are concerned, and justly so, in consequence of the harsh treatment they usually received; and I can assure you that the Council did not fail to represent to the authorities the effect of such an unsatisfactory and unjust arrangement, which unquestionably tended to prevent the reporting of defaulters, and consequently to frustrate the provisions of the law. The Council, in the most forcible manner, urged the Government to provide for payment of a fee of *not less than one guinea a day*, nor exceeding two guineas a day, to each medical officer required to give evidence. (See the correspondence on this subject between the Council and the Local Government Board, and also with his Grace the Lord Lieutenant, published at the time—see report for the seven months ending 21st January, 1879, pp. 17 to 27—in the reports of this Association, and which, no doubt, evoked the new legislation).

The Government appear to be under the impression that this section will be fairly and liberally construed by the justices, and that, in future, each medical officer required to give evidence in such cases will be allowed the maximum fee of one guinea a day; every medical officer, therefore, who in future may be refused the fee of one guinea a day should promptly inform me, briefly, of the facts, in order that the Council may have the earliest opportunity of supporting, by evidence, the claims of the medical officers to a more equitable arrangement for payment of such fees.

It is to be hoped that occasion will not arise for questioning the course which the justices may see fit to adopt; but if it should, and that there are many instances of injustice to cite, the Council expect that they will be able to obtain from the Government a more satisfactory egulation in this behalf.

The 11th Section provides that a dispensary medical officer, who is not the registrar of births and deaths for his district, shall be kept informed—once at least in every month—of the particulars necessary to enable him to make out the returns of vaccination defaulters (Form P), but it does not affect anyone who holds the two offices of dispensary medical officer and registrar of births and deaths.

So far I have referred only to the provisions of the new Act as is stands, I will now briefly direct attention to its faulty omissions. The Bill drawn up by the Council of the Irish Medical Association suggested that the system of inspection and awards, now in operation in England, should be extended to Ireland, by which every dispensary medical officer who efficiently discharged his duties as a public vaccinator would, upon a favourable report of the results, be allowed a gratuity or premium of one shilling for each vaccination performed by him, in addition to the sum of two shillings allowed for each successful case. I am happy to be able to inform you that the justice of the claims of the Council, to the extension to Ireland of this system, has been unceasingly urged upon the Government by Mr. Meldon, M.P., and the Council are sanguine that, at no very distant period (probably in the next session of Parliament), their demand will be granted.

In many respects the new Act is not at all satisfactory, nevertheless it is all that could be ohtained; and it must be admitted to be a great improvement on the previously existing law.

The Council made a desperate struggle for a fee of half-a-crown for each successful vaccination, and did not yield this, or any of their demands, until within a few days of the end of the session, and then only because the alteration of *even one word* in the Bill would have been fatal to its passing. At the very last moment, but not until then, Mr. Meldon, M.P., was requested to withdraw all opposition to the Bill, and to endeavour to secure its being made law; but, owing to the opposition of Messrs. Brown, Hopwood, Biggar, King-Harman, and at the last moment of Mr. Macartney, especially, he found it very difficult to get all the amendments on the paper withdrawn; however, his great tact and ability were equal to the occasion, and it is chiefly to Mr. Meldon's exertions, supported by Mr. Mitchell Henry and a few othe members, that the law has been so far modified; and it is hoped that Mr. Meldon's valuable services will be duly appreciated by the members of the medical profession in Ireland, in whose interest he has been so able an advocate on this as well as on so many other occasions.

The Council also suggested the adoption of the term "public vaccinator," to comprise the dispensary medical officers and all other medical practitioners recognised by the Local Government Board as discharging such functions, but their suggestion was discarded; it remains therefore to be seen how the medical officers of the vaccine department of the Local Government in Dublin are affected by the new law, which does not appear to place them on an equality with the dispensary medical officers as regards remuneration for their services; but it is hoped that the Local Government Board have power to prevent such an injustice to their own more immediate officials.

With regard to this measure, the Council were placed in the very difficult position of having to accept or refuse the Bill *in toto* as it stood, it being utterly impossible to obtain the alteration of even a single word; but as several important amendments suggested by the Council had been adopted during the early stages of the Bill, they, under protest that it was not sufficient, deemed it expedient to accept the Bill, and thereby secure the advantages it confers, rather than refuse all, with only a mere visionary prospect of obtaining even those self-same advantages upon a future and probably remote occasion, if ever; and they trust that their action will meet with the approval of the profession.

As it is comparatively easy to prevent the passing of a Bill, the difficulty of getting one passed is consequently extreme; yet many members of the Association do not appear to recognise this fact, nevertheless the difficulties the Council have to contend with regarding legislative measures are simply enormous, to say nothing of the great expenses necessary to be incurred; and there can be no doubt whatever in the mind of anyone who is acquainted with the practical working of a medico-political body, such as the Irish Medical Association, that in order to obtain reforms in the law, energy, ability, unceasing hard work, devotion, and above all, ample funds are essential; and further, that but for the existence and energetic action of the Irish Medical Association the position of the members of the profession would have greatly deterio

Digitized by Google

rated, and their official incomes seriously diminished, in consequence of the immense adverse influence of the ratepayers' representatives.

In conclusion, I would remind you that the new Vaccination Act is but a modification of the Bill drawn up and suggested by the Council of the Irish Medical Association, which advocated many important pecuniary and other advantages not as yet adopted by the Government, but which, the Council trust, may at no far distant time, at least gradually, be enacted.

In view of this prospect, and especially of what has already been obtained, as well as of the absolute necessity of funds sufficient for the purpose, I have again to request that every member of the profession in Ireland, who is not as yet a member of the Association, will now see the advisability of joining it and paying the insignificant and modest subscription of only ten shillings and sixpence a year, as a recognition of the most recent of many important advantages obtained for him through its zealous and untiring exertions, whereby, as is now announced, his income as a public vaccinator has been *doubled*. It is but poor encouragement to be supported by only one-third of the two thousand medical practitioners of Ireland who reap the benefits derived. If all were members of the Irish Medical Association, as they should be, the grievances of the profession would rapidly vanish.

As those who are not members of the Association are naturally reckoned as opposed to its action and demands (and they are in the proportion of two to one), the influence of the Association for the general benefit represents only one-third of the whole.

The effect of this want of union of those interested in their own welfare—which is doubtless due more to apathy, parsimony, timidity, or expectation of passing unobserved, rather than to a want of sympathy in the objects of the Association—is unquestionably a retardation and diminution of the recognition of their services, which the members of the medical profession in Ireland can only expect and obtain through the efforts of the Irish Medical Association.

I append a form which I trust every non-member will forthwith fill up, sign, and return to me without delay, announcing his intention to support the Association which has done so much, and has yet so much more to do, for the promotion and protection of his interests.

Of each non-member I would ask—will he help the Association to help himself? And if not, does he accept the benefits already obtained, towards which he has not contributed? Nay more, the earlier acquirement of which has been retarded by his own non-support of the Association? And I confidently expect an immediate reply from each in acknowledgment of realised benefits, promising what assistance he can give to obtain still further advantages.

I am, dear Sir,
Yours faithfully,
JOHN H. CHAPMAN, Hon. Sec.

ATHY UNION.

THE HOSPITAL RETURNS.

THE following letter was read :—

"Athy, October 8th, 1879.

"DEAR SIR,—I beg to acknowledge the receipt of a copy of a resolution adopted by the Board of Guardians at their meeting on the 23rd ultimo, whereby I was requested to make out certain statistical returns, and present them personally at the meeting to be held on this day. In reply, I have to say that the pressure and paramount importance of my professional duties prevented me from complying with that order; and besides, I have to submit that I do not consider it is part of my duty to do so. It is not for me to question the object, proximate or remote, which the board have in this matter; but I may be permitted to conjecture that it is for the purpose of determining to the board's satisfaction whether the alcoholic treatment, as it is administered in the union infirmary, is not calculated to shorten rather than prolong the existence of the patients. If this be so, there are not any data on which I could formulate statistics to satisfy them on the point, as eight-tenths of our admissions to that compartment are composed of persons labouring under incurable diseases or senile decay which would under any circumstances prove fatal sooner or later. The class from which useful inference could be drawn do not take advantage of our institution, as they consist chiefly of domestic servants, farm labourers, and tradesmen in the prime of life, who have a profound objection to be branded with the social stigma of pauperism, and, therefore, when afflicted with illness, either remain at home under the care of the dispensary physician, or, when capable of removal, seek relief in the more respectable atmosphere of a county infirmary, or metropolitan hospital. Our fever hospital, to which all classes labouring under infectious or contagious disease, as a rule gain admission, compares favourably with any institution in the land, both as regards the paucity of deaths in proportion to admissions, and the quickness of convalescence. To none of these classes of patients do I administer alcohol carelessly or recklessly, but prescribe it cautiously and carefully, having in view in case of incurables the assuaging of the pangs they have to suffer in their passage over the rugged road to the last scene; and of the others, the tiding of valuable lives in a time of stormy and critical peril to the haven of convalescence, and subsequently to hasten the latter beyond the line which separates it from complete restoration to health.—Yours very faithfully,

P. L. O'NEILL.

Dr. O'Neill—I do not think the guardians could derive any further information from the return, even if I had time to make it out. But it is no part of my duty to make out such returns, and if the guardians compel me to do so they will have to pay me. But the public mind should be disabused of the idea that the patients here are dosed with stimulants. Nothing could be more erroneous. The stimulants are measured out with the same accuracy as the poisons. I never administer them only where I find them absolutely necessary. I cannot be considered extravagant, for I consider I often err on the side of economy.

Mr. Redmond considered it was the doctor's duty to prepare the return. He was most anxious to ascertain the cost of drugs, as he had a motion to bring forward, but he was prevented from doing so in consequence of not having the return, and that was one of the reasons the return was moved for by Mr. Lefroy. According to Article IX. of the General Orders the doctor was bound to find the guardians any information they may require. In support of this contention, Mr. Redmond read the article referred to.

Dr. O'Neill—That has reference to any case of illness I may have under my care, a report of which you have every week from the master.

The guardians considered the explanation of the doctor satisfactory.

ANOTHER MODEL IRISH GUARDIAN.

THE county of Louth obviously enjoys special benefits from the services of the sort of persons who manage its public Poor-low affairs. We felt it necessary recently to resent the insolence of a roadside squireen at Ardee, who thought it fitting to apply publicly to the medical officers of his district language to which his tongue is, no doubt, well accustomed in his personal affairs. The local paper lifts last week from insignificance into a discreditable notoriety a person named M'Kenna, who, some way or other, has managed to get himself into the board of guardians. The occasion on which this person distinguished himself was the voting of a consultation fee to Dr. Murtagh, for his services in a midwifery case. Here is the debate thereon :—

Mr. Daly—You may vote a guinea as the fee, you have

Digitized by Google

to get the man to take it. I met Dr. Kelly, and he said he would not go to any case such as Dr. Adrian called him in for, where surgical aid was absolutely indispensable, without a fee of £2 2s.

Mr. M'Kenna—It is all nonsense to be talking in that way. If one of these situations was open to-morrow you would have a dozen of doctors running after it and ready to take at £60 and £70; duly qualified men, too. No less than nine doctors came to ask me for my vote, humble as I am, when the last vacancy was here.

Mr. Farrell—Dr. Murtagh told us here distinctly to-day that he would not go for £1 1s.

Mr. M'Kenna—What if he doesn't? Let him resign; you will get sixty to take his situation to-morrow. Mechanics are of more importance to society than doctors or professional men, and yet when they dicate their terms you take a firm course with them. I ———

Mr. Daly—What's the use of talk like that; keep to something like what's practical.

Mr. M'Kenna—Take the case of tailors. Well, if all the tailors were to hold back from work, men would have to go naked, and the cold, in our artificial state, would perish all our fine gentry off the face of the earth. Still, important to society as tailors are, you do not allow them to dictate their own terms to you. If they, or any other mechanic, enter into a combination or strike, you meet them with their own weapons. Do the same here. If you appoint the doctors and that they dictate their terms to you, and enter into a combination, just deal with them as you would with any other class of men on strike.

Mr. Whitworth said Mr. M'Kenna had referred to the case of tailors as a parallel one. The tailor has got a piece of cloth to cut out; the doctor has to cut into the human body; a slip of the scissors with the tailor cannot do much harm—a new piece of cloth can be got; a slip of the knife in an unskilled hand may cost the patient's life, that never could be restored. (Hear.) The amount to be paid therefore to skilled hand for an operation was the value of a human life.

Mr. M'Kenna—You may say oh! but it's a fact; all the people that lived a hundred years ago—doctors and all—are all dead and gone. The doctors couldn't keep themselves alive, and small blame to them that they couldn't keep others; and all the people alive to-day will be all dead as Julius Cæsar before another hundred years, notwithstanding all this wonderful medical skill and science we hear such puffing about. What with Latin and prescriptions they get people to believe they work wonders, when in the great majority of cases they take credit for what our good old nurse—Mother Nature—does for us. I wouldn't give that for the knowledge of some of them. A most able physician in Glasgow went into a hospital a short time ago and cut the tongue out of a man's head in the most skilful manner possible, and the man died in an hour after. It is a mistaken idea when we think a doctor is required in a case of midwifery. Where were the doctors, I'd like to know, in the time of the Pharaohs, to bring all the children of Egypt into the world? How was it that the people of these far-back times, before doctors were to be had so plenty as they are to-day—how was it that they lived so long and enjoyed such good health and length of days, I'd like to know? There is no doctor wanted in a case of midwifery; Nature knows how to conduct her operations to a successful end in such cases without a doctor. It is all gammon, for the most part, we have been listening to here to-day from Mr. Daly and others.

We should not think it worth while to notice the remarks of this precious representative of the Drogheda voters from anything that either his opinions or he are worth, but we think it well to lose no opportunity of pointing out how hopelessly unfit for any public duty are some of the persons who are sent to boards of guardians. We always said that the hobby of local government has been ridden to death, at least in Ireland, and we need hardly offer arguments to show that it is a cardinal mistake to entrust the administration of sanitary medical law to a system under which it is possible to have such persons as these in the local executive.

FEES FOR INSURANCE CERTIFICATES.

The following proceedings have raised a question of some interest, and we therefore publish them, though they have been unduly delayed.

LIMERICK UNION.

The following letter was read;—

"My Lord,—In the published reports of the proceedings of your board, I have read with some surprise a statement 'That I had refused without payment of a fee of 10s. a certificate of the death of an inmate of this house to the relative of the deceased who had the life insured, the insurer, Mrs. Ryan, being at this moment in receipt of out-door relief from your board; also that the amount for which the certificate was necessary was a mere trifle for burial purposes, for which but a penny a week or so was payable.

The following were my reasons for demanding a fee in this case:—1st. Where a certificate of a physician is required by an insurance office, all medical men in Ireland require a fee of at least 10s.; but where the sum payable by the company is under £10 no certificate is required and no fee asked. 2nd. With regard to Mrs. Ryan, it is true that she has four children, and has been during her husband's illness in receipt of 4s. a week, but I knew that the insurance money had been over £10; also I believed then, as I do now, that though receiving out-door relief from your board through Mr. Myles, she is not destitute, especially as I have been informed that this woman is carrying on some small business, and has four children grown up, in good health, and three of them employed earning wages, and that a sum of money had been subscribed for her by the pig-buyers' society—to which occupation her husband belonged—of from £20 to £30 on the death of her husband.

"Your obedient servant,

"T. O'Dwyer Russell."

Chairman—I don't at all think that it in any way contradicts the statement made on the last board day. I heard that Dr. Russell refused to give a certicate of the death of the deceased without first receiving his fee. He does not deny that, he states in his latter that such was the case. I knew that the woman who applied for the certificate of the death of the deceased had his life insured at a penny a week, and at her husband's death was to receive something like £10. I did not at all know that she was carrying on business in a shop; I believed her to be very poor when she was receiving out-door relief, and certainly I thought it very curious, she at the time being represented as a very poor person, that Dr. Russell should refuse to give her a death certificate without first receiving his fees.

Mr. Cronin—We cannot at all control our medical officers. Dr. Russell was fully justified in asking his fee when he thought the woman in question was well able to afford to give it; and I say still that it is impossible that we should have any control over our medical officers. I say that Dr. Russell was fully justified in asking for his fee when he was assured the woman was able to give it. The woman, it has been stated, was in the receipt of 4s. a week out-door relief.

Dr. O'Shaughnessy—Well, gentlemen, I now propose that the slur which was cast upon Dr. Russell be at once removed by the board; and also for the board to say that they are quite satisfied with his explanation.

Mr. Bassett said he was quite sure the board were willing to accede to Dr. O'Shaughnessy's proposition.

Alderman Myles said they were after tying his hands from trying to do their business for the interest of the ratepayers. (No, no.)

Dr. O'Shaughnessy—Oh, no! Mr. Myers. We would be sorry to do that.

After some further discussion, the board considered Dr. Russell's explanation, as to his right of demanding a fee, satisfactory. The matter then dropped.

INTRAVENOUS INJECTION OF MILK.

By AUSTIN MELDON, L. & F.R.C.S. Irel., L.K.Q.C.P.I., M.R.I.A.,

Surgeon to Jervis Street Hospital, formerly Demonstrator of Anatomy in the Catholic University of Ireland, &c., &c.

At the meeting of the British Medical Association held in August last, I read a paper on the intravenous injection of milk, illustrated by five cases. Since that time I have operated on three other patients with such favourable results that I deem it to be my duty to place the cases on record.

Lately a good deal has been written against the operation, and much trouble has been taken to show it is unphysiological. At present I do not purpose dealing with the subject on theoretical grounds, although much can be said even in this way in favour of the operation, but will be content to draw attention to the practical results of the operation. I may remark, however, in passing that the conclusions drawn from the experiments on dogs can hardly be taken as conclusive in so much as in these experiments, far too large a quantity of milk (comparatively speaking) has been used. It has been conclusively proved that if a large quantity of milk be injected into the human subject the operation is attended with the greatest danger. It has been urged that the oil globules are too large to pass through the smallest capillary vessels. The following cases show this assertion to be fallacious :—

E. J. M., a delicate-looking gentleman from Cheshire, æt. 30, first sought my assistance on the 29th November, 1878. He complained of pain in the head and back, loss of flesh, strength, and energy, slight intercurrent diarrhœa, and inability to sleep for more than one hour at a time. On examination I found the temperature 100 deg., the pulse 110, and considerable tenderness and gurgling in the ileo-cæcal region. A few rose-coloured spots were visible on the abdomen.

From the account given to me and from these symptoms I came to the conclusion that he was in the third week of typhoid fever.

During the next three days there was but little change in his condition, except that the treatment improved his sleep at night, but his temperature and pulse remained high.

On the fourth day there was a smart attack of diarrhœa, which was checked with kino, catechu and opium. On the 4th December the temperature was 105, and some blood had been passed at stool. On the 6th the temperature was 106, and the pulse 120. There had been a slight bleeding from the nose, a good deal of blood from the bowels, and recurring diarrhœa. During the next four days he improved somewhat. From this time, however, the temperature gradually rose until the 10th, when I was hurriedly summoned to his bedside. I found him in complete collapse, almost pulseless, breathing forty times in the minute, and the respirations short and incomplete. This condition, as well as what I learned from his friends, left no doubt in my mind that perforation of the intestines had occurred about half an hour before I saw him. Two grains of opium were at once administered, and repeated in two hours, and other appropriate treatment adopted. For some days he was kept almost completely under the influence of opium. A considerable amount of peritonitis ensued, and until the 17th December he was considered in a hopeless condition. From this date the temperature commenced to fall, and the pulse decrease in frequency and increased in volume.

On the 25th the temperature was but 98, and three days later he had a solid motion. From this date he took plenty of nourishment, *yet rallied very little.* On the 3rd January severe diarrhœa occurred, which reduced him to a moribund condition. Next day he was better, and continued to improve for a few days, when the diarrhœa recurred. Bed sores now formed.

Digitized by Google

In this way matters went on till the 15th, when I made up my mind that his life could only be saved by transfusion. Having got the consent of his parents to the operation, I asked my friend Dr. Lyons to see the case in consultation with me. His opinion was, however, that in his then exhausted condition even the slight shock of the operation would prove fatal. He recommended that the body should be sponged with warm milk, and that he should be put on large doses of nitrate of silver. The result of this treatment was a slight improvement, which however lasted only a few days, when he gradually relapsed into his former exhausted condition. The thought of transfusion again occurred to me, and I made up my mind to try its effect. With this view I sought the assistance of my friend Dr. Robert M'Donnell, who, I knew had very considerable experience in the transfusion of blood. In consultation we agreed that it was a suitable case to try the intravenous injection of milk.

On the 23rd January I obtained a cow from Mr. Moore's extensive dairy yard, selecting one whose milk was of medium quality. Immediately before the operation the animal was milked on the premises, and the milk kept at the temperature of 98 deg.

The apparatus used in the injection was Dr. M'Donnell's simple but efficacious transfusion instrument, which, as is well known, consists of a glass funnel, having attached to it a piece of india-rubber tubing, with a small bulbous enlargement in the centre, which enables the fluid to be injected in jerks. The India-rubber terminates in a nozzle which is introduced into the vein.

Everything being ready for the operation, an incision was made over the median basilic vein of the left arm, which was then cleared and raised—a large needle being passed under to steady it. The vein was now opened, the canula introduced, and slowly about ten ounces of milk injected. The operation lasted nearly fifteen minutes. During the injection the pulse increased in force, the patient complained of great cold, and his face became of a dusky hue. No sooner had the operation been finished than the respiration became very much obstructed, the patient gasping for breath, and the fingers, feet, and lips became cold and livid.

The operation was performed at a quarter past one. At two o'clock his condition was as follows :—Temperature 96, pulse could not be felt, respiration 40, unable to speak, feet cold, lips and fingers livid, hiccough, and very restless, tossing about his head and arms. Burnt brandy, a subcutaneous injection of ether, and mustard leaves over the heart were ordered. During the next hour he remained pretty much in the same condition, those about him expecting every moment to be his last.

At 3.30 the respiration become more tranquil. At 5.30 the temperature was 100 and the pulse 110, respiration 24, feet warm, felt very thirsty, could speak well, and has taken during the previous hour a fair share of nourishment. At 11 p.m. his temperature was 98, his pulse 100, respiration 18, has a very healthy look, has been able to take nourishment freely, is much stronger and in very good spirits, says he feels quite well, is sitting up in bed describing his travels while he was yachting during last summer.

23rd, 8 a.m.—Has passed a very good night, has taken nourishment freely throughout, is in good spirits, and has not had diarrhœa. Temperature 98·2, pulse 96.

24th.—Pulse is much improved in character, no diarrhœa, but a small solid motion.

25th.—Bowels very healthy ; temperature 97, pulse 96.

26th.—Temperature still 97, pulse 100 ; has had a little diarrhœa, is rather weaker.

27th.—Temperature 97, pulse 110, diarrhœa has been checked, bed sores just healed, has slept well, and has taken nourishment freely.

28th.—Diarrhœa again severe ; weaker.

31st.—Pulse 120 ; is very weak and nervous.

Feb. 1st.—Proposed to inject milk again, but patient would not consent. He is still weaker.

2nd.—Continues to lose strength ; feels he is dying ; parents have very little hope, but will not consent to a repetition of the operation.

3rd.—Diarrhœa continues ; legs also swollen ; pulse intermittent, much quicker ; subsultus tendinum.

5th.—Pulse hardly perceptible ; respiration difficult ; diarrhœa checked ; has slept a little ; temperature continues 97 ; pulse 140.

6th.—Has consented to a repetition of the operation.

At 12 o'clock, having procured the same cow as on the last occasion, and having everything ready for the operation, I made an incision over the median basilic vein of the right arm. This I found in such a collapsed condition that it was with great difficulty I could satisfy myself that it was the vein I had raised. I injected 4½ oz. of milk at a somewhat higher temperature than that used at the former operation. The same symptoms followed, but in a much milder degree, and only lasted for about twenty minutes. The temperature rose to 101. The pulse became much stronger, and for some short time he seemed to be much improved.

Just two hours after the operation he remarked that his arm was numb, and on looking at him I perceived that he had a slight epileptic convulsion, after which for a few moments he became almost insensible. Three times within the next twenty minutes he had a repetition of these convulsions, each one of which only lasted a few seconds, and were followed by gradually increasing longer periods of insensibility. The last of these, which was of a more tetanic character, proved fatal.

P. M., æt. 27, a policeman, suffering from phthisis, consulted me about the 26th January last. I had seen him about a year previously, when he had extensive deposit in both lungs. I now found him in the last stage of consumption, both lungs and larynx being engaged. For some weeks there had been constant diarrhœa, and both legs were much swollen. All my efforts to improve his condition or to check the diarrhœa having failed, and his only anxiety being to be able to be moved home, a distance of upwards of 40 miles, I entertained the idea of injecting some milk into his veins. With this view I asked my friend Dr. Collins to see the case, but his opinion was rather against the operation, as he did not think it could be of any service to him.

About 2 o'clock on the 7th February I was summoned to his bedside, and found him moribund. The friends were most anxious that transfusion should be tried. Yielding to their earnest solicitations, I injected about 2¾ oz. of milk into the median cephalic of the left arm. The respiration immediately became hurried and the face somewhat livid, but the usual symptoms were not so severe as on the former operations, and the patient expressed himself greatly improved. I saw him again that evening, and I found that the diarrhœa had been completely checked, and that he had improved much in spirits and in strength. There was some albumen in the urine. The temperature was 100.

Next morning, the 8th February, he felt so much better that he dressed himself without assistance, and without fatigue was able to go to Moate, a part of the County Meath, by train, a distance of upwards of 40 miles.

T. W., a druggist, æt. 42, residing at Skerries, first consulted me on the 2nd May. The history of his case he thus gives :—

"Twenty-eight years ago I was seized with fever, accompanied with obstinate constipation, loss of appetite, and great prostration. From this I recovered very slowly, and remained for a considerable time extremely weak, and almost unable to walk.

"On several occasions since I had a recurrence of these symptoms. For twenty years I have had large ulcers on my legs, which have only within the last few years healed. The only medicine I took was sarsaparilla and iodide of potash. The attacks have been more frequent of late, and I have lost flesh gradually."

He was supported into my study, being unable to walk

Digitized by Google

and I have never seen any one so attenuated—being, in fact, little better than a skeleton. For some weeks he had been unable to dress or do anything else for himself. I failed to detect any pulse at his wrist; his heart's action was barely perceptible, and in a word, his condition was such that I felt very uneasy lest he would die in my study. I strongly advised him to remain in town, and ordered him ammonia, ether, and other stimulants. I saw him that evening, when he had revived a little, and for a week I attended him without being able to perceive any further improvement.

I suggested to him the advisability of having milk injected into his veins, and he readily assented, as he looked upon himself as in a very hopeless condition. On the 12th May I injected 6 oz. of goat's milk, which had been rendered more distinctly alkaline by the addition of some ammonia, into the median basilic vein of the left arm. During the operation his breathing became hurried, and he was continually sighing and yawning. His pulse improved, and his face became somewhat livid, but in about an hour's time, this latter, as well as the hurried respiration, subsided. Soon after, he commenced, and remained during the day, perspiring profusely. The temperature rose immediately after the operation to 104 deg., but towards evening sank to 98·1 deg. No albumen was perceptible in the urine. Next morning his pulse was much stronger than I had before known it, and his appetite was greatly improved; he had some colour in the face, that before the operation was a ghastly white, and during the night he had slept well.

14th.—Is somewhat low this day, and has had a little bilious vomiting.

15th.—Greatly improved; appetite much better; feels stronger; pulse continues to improve.

18th.—Sat up for a while in bed; pulse better; appetite good; and is in good spirits.

19th to 22nd.—Continued to improve, and a few days later was able to return home.

Has since continued to improve.

S. M., æt. 52, was a healthy woman all her life until about four years since, when she discovered that she had gradually been losing flesh for some time, and also that her appetite had of late considerably failed. During the past two years she has suffered much from cold feet and loss of sleep and strength.

I first saw her about nine months ago. She was then greatly emaciated; eat little; complained of severe headache, pains in the calves of the legs, and shortness of breath on the least exertion; her pulse was very weak, but no organic lesion could be detected. Six months' treatment, during which she took nourishment, tonics and stimulants in every form, failed to arrest her disease. Ten days before I operated on her she was confined to bed, unable to stand from weakness. She cared very little for food, and her friends expected her death every moment. On the 30th of May I injected 6 oz. of goat's milk, at the temperature of 100 deg., into the median cephalic vein of the left arm. The usual train of symptoms followed. Her temperature reached 104 deg., but she expressed herself as feeling very comfortable, and during the day felt stronger and better than she had for twelve months. Next day she was able to take with relish a considerable quantity of nourishment, and was able to walk across the room. Each day I found her improved, until the 10th of June, when she was able to sit up the entire day. On the 15th of the same month she was able to walk in the open air, and a week later, was strong enough to visit her solicitor and transact her usual business. Since that date she has continued to improve.

M. M'G., æt. 39, has been the subject of well-marked phthisis for upwards of twelve months. Of late he has lost a considerable quantity of blood from the lungs, and since the 15th of May his friends have been in daily expectation of his death. On the 16th of July I injected 3½ oz. of goat's milk into the median basilic vein of the right arm. The goat, which was brought into the bedroom, was not milked until the vein was raised, and Dr. Collins, who assisted me, tested the milk as it left the udder, and found it distinctly acid. Immediately on being milked, 10 grains of carbonate of ammonia were added to 10 oz. of the milk. The operation *was not followed by any disturbance of respiration*, but the pulse became much stronger, and the temperature rose two degrees. Since the operation the patient has become materially improved.

The history of intravenous injection of milk is not without interest. Dr. Edward M. Hodder, of Toronto, Canada, was the first to perform the operaton, and he was led to use it by the fact that Donné had without injury injected milk into veins of both dogs and rabbits. Dr. Hodder performed it in 1850 on three persons, moribund from Asiatic cholera, injecting as much as fourteen ounces at one operation. Two of these cases recovered. Strange to say, for twenty years the operation was not repeated until in 1873 Dr. Joseph W. Howe, of New York, injected six ounces of goat's milk into the cephalic vein of a patient dying from tubercular disease of the stomach, and mesentery. The operation does not seem to have had any influence on the termination of this case, the patient having died four days afterwards. In the following year a patient of Dr. Gillard Thomas, of New York, who was fast dying of hæmorrhage from the uterus after ovariotomy, was saved by the injection of six ounces of milk. It was next performed by Dr. Howe in a case of phthisis, but the patient died comatose in four hours after the operation. Sometime later he transfused four ounces of goat's milk into the veins of a woman far advanced in phthisis, complicated with syphilis, and this operation was followed by marked improvement. Subsequently, Dr. Thomas had other patients, making in all three cases and seven operations performed by him. Drs. John H. Brinton and Charles T. Hunter have also operated successfully on several cases. Dr. J. C. Hutchison and Dr. Bullard have each had one case. No European ones have been published.

The five cases which I have now read to this Association make twenty-two, the total number as yet on record. A careful analysis of these cases is most favourable to the operation. For this purpose I am disposed to divide them into four classes:—

First. Those in which the operation cured the disease, which necessitated its performance.

Secondly. Those in which the operation prolonged life.

Thirdly. Those in the which the operation was productive of neither good nor evil.

Fourthly. Those in which the operation, in all probability, shortened life.

The first class includes eight cases; the second ten; the third two; and the fourth two.

The eight patients cured by the operation consist of two cases of Asiatic cholera, four of pernicious anæmia, one of impending death from hæmorrhage, and one of gastric ulcer. All these patients were in a hopeless condition, and the operation was only undertaken as *un dernier ressort*. In one of the cases of anæmia (Dr. J. Hutchison's) transfusion of blood had been first tried, with out the slightest benefit.

In the two fatal cases, the results may be traced to the fact that the milk was either acid or kept for too great a time before transfusion, or too large a quantity was injected.

It has been conclusively proved that if milk, which has been kept for any considerable time, be injected into the veins of dogs, it invariably proves fatal, whereas, if used directly after being milked, it can be injected with impunity.

The severity of the symptoms following the operation is in direct proportion to the quantity injected. ounces should, I believe, be the largest quantity inje at one time. As much benefit seems to follow the u four ounces, and far less alarming symptoms than af larger quantity.

Digitized by Google

I do not think it is necessary to strain the milk, if it be milked into a perfectly clean vessel, but I think it would be well to add a few grains of carbonate of ammonia to each injection. I did so in my three last cases.

It is not generally known that milk taken from some animals which have been in confinement for some weeks is slightly acid, even when it leaves the udder.

In three of the successful cases the milk was boiled before being used.

The presence of albumen, I think, is accidental. I found it in two of my cases, but then both patients had been taking considerable quantities of white of eggs, to check diarrhœa.

In conclusion, I have only to add that unless future experience changes my ideas on this subject, after a careful consideration of the cases published, as well as from the experience of my own cases, I have made up my mind that I will not allow any patient under my care to die of exhaustion without an attempt to save them by the intravenous injection of milk, and I am strenghthened in this resolution by the knowledge that out of twenty-two cases in which it has been resorted to, eight lives have been saved, and ten others prolonged by this operation.

FURTHER OBSERVATIONS ON CONSUMPTION.

II.

By William H. Pearse, M.D.,

Physician to the Plymouth Public Dispensary.

During the past four years I have been systematically treating phthisis by arsenic; the physical signs have been carefully recorded at the first consultation. My case-book has now over two hundred and fifty of such recorded cases, which have been more or less under the same treatment. The difficulty of keeping cases steadily at treatment, the fact that a very large proportion of the patients, not presenting themselves after the second time, and thus, for a time, being lost sight of, makes results imperfect; not the less, I have been so often made cognisant of good results to cases, that I think a notice of the experience may be of value.

The arsenic has been given mostly in the following form:

Liq. arsen. hydrochlor., ℥ lxiv.;
Quiniæ sulph., gr. viij.;
Acid hydrochlor, dil ʒiij.;
Syrup aurant, ℥j.;
Infus chirettæ, ad ℥viij.

This mixture equals sixteen doses, of which one was taken three times a day, after meals. In many cases ten minims of sea water were added to each dose; in others two grains of sulphate of manganese. The patients were directed to continue the medicine during six weeks, then to allow an interval of a week, and again to resume treatment. Although some patients have taken arsenic in this way, during periods of a year or more, in no instances have any untoward symptoms shown. About fifty of the cases took 1-120th of a grain of arsenic (acidum arseniosi) in pill, combined with three grains of the powder of the dried vesicles of the fucus vesiculosis; the vesicles were collected in September, in which season they are full of a gelatinous secretion.

However true it may be, that many consumptive cases follow chronic and repeated bronchial attacks, such are insignificant in number, compared to those which develop naturally at certain ages, in certain well marked vito-physically typed individuals. Taking such individuals in the early stages of the failure of their health, and prior to advanced stages of tubercular disease of the lungs, the aim has been to sustain their general health, and thus to prevent tubercular deposition; to seek to supply to the body certain mineral and other elements, which should co-ordinate the growth of lung tissue to normal and healthy rates. The human body is viewed as an evolved and evolving series of being, correlated to all physical existences; where failure of the healthy growth of tissue at certain ages — *e.g.*, of the lungs—occurs, physical causes must exist for such deviations into disease; such wants of full physical correlation, may be mostly in the absence of the full external relations, which are essential to, and one with, living beings, or yet more in inherent defects of the composition of the body itself.

Physical types.—Viewing the cases, and of which the larger proportion were in early stages, certain physical types of body arrest the attention; such anatomical types or states are noticeable in the teeth, hair, eyebrows, skin, nails, alæ nasi, &c.; the physical type varies much in different cases, but some one or more of such changes may be tracedin most; in previously robust men of over forty years, who pass into phthisis, I have generally found one or more such anatomical types. The teeth have often beautifully white and semi-transparent enamel; the changes in the teeth, which indicate a probable future development of phthisis, and which for periods varying from months to years, precede the deposit of tubercle in the lungs, are the lateral decay of the upper incisors: little dark spots of decay appear, often in a well-marked crescentic form. I have endeavoured to correlate their decay with changes in one or other lung; the following is the result since I commenced to record the state of the teeth: where the right and left upper incisors were gone, the right lung was diseased in six, the left in eight cases. Where right upper incisors were gone, the left lung was diseased in seven; the right in no case. Where the left upper incisors were gone, the left lung was diseased in six, the right lung in four. All the upper incisors were gone in fourteen cases in which phthisis was in early stages. In only two cases, where phthisis was developed, were the upper incisors sound.

The number of cases under observation has been far too small to indicate the exact prevailing order of relation in time and place of upper incisor decay and lung disease; not the less, however, a very pronounced relationship will be found between the early lateral decay of the upper incisors, and the subsequent deposit of tubercle in the lungs: the phenomena appear to be parts of one series.

When such lateral decay of the upper incisors appears, in somewhat delicate young people, they may adopt that mode of life most likely to ward off phthisis.

Another marked anatomical feature in many who are passed into, or will pass into phthisis, is an excess of the natural lateral twist of the upper maxillary region, nose, &c.; the nose and upper incisors unduly twist to one or other side. We see this commonly as a normal condition in the middle-aged and old, but it often earlier shows, and in a greater degree, in those who are phthisical. Since I began to record this condition, my cases are far from numerous enough to indicate, with probability even, the exact relation of disease in one or other lung, to one or other of the lateral directions of the upper maxillary segments of the body: where the twist existed to the right, the left lung only, was diseased in four cases; both lungs in two cases; the right lung in two cases. Where the twist was to the left, one case only has presented, the disease was in the right lung. Other well marked anatomical conditions, chiefly of the skin system, exist in those who tend to phthisis: an exquisite softness and fineness of the skin has long been recognised as frequently associated with phthisis; we may often see the exquisitely-shaped and semi-transparent nails, the hair is often in great amount, a very considerable number have shown shaggy large eye-brows, and which tend to meet in the mesial line; the hair of the whiskers and beard may be lank and thin, and scattered.

Although the great proportion of consumptive persons are of the fine-boned type, with small chest and delicately cut features, yet there are very marked exceptions; in one splendid young man, whose thorax was well developed in the infraclavicular regions, the lungs rapidly

Digitized by Google

broke up; he had the peculiarity of eye-brows, heavy and meeting in the mesial line. Some few women also have had the thorax and mammæ well developed. The hands are often abnormal, being variously large and cold, or exquisitely shaped, or cold and small, &c.; some few women have shown the skin more downy with hair than is common.

Anatomical conditions involving the order of the evolution or development of the supermaxillary segment, and of the whole skin system, are correlated to tubercular growth, as in some degree parts of the same series; such phenomena point to some morphological law or order, which shall embrace phthisis, as related to such anatomical changes. When we remember that in the phenomena of goître and cretinism, the actual bones of the base of the cranium may be altered, and that such a fundamental change in man, is dependent on some small but slowly acting physical condition; and further, when we remember that some of these diseased changes may be arrested by a mineral element (iodine), we have strong analogy for expecting that some small defect in physical composition or co-ordination may be the condition or cause of the failure of vital "energy," at certain ages of the individuals, of the lung nerve segments; and we are led by analogy to the further hope of being able to supply the system with its just composition and co-ordination, so that the deviation into phthisis cannot occur.

Phthisis must be viewed not as a distinct disease, or "specific" existence, but as a varying deviation of normal growth, a varying failure of vital formative energy. The phenomena of phthisis appear after varied depressions. Thus phthisis appears after a group of fevers (measles, &c.), in those who habitually go to bed cold; from the mentally depressing influences and confinement of nun life; from the change from out-of-door to indoor life negroes in Demarara); from want of proper food, &c. Phthisis thus appears within the circle of those phenomena of the animal kingdom, which, latent in the system, reappear under certain depressing influences, and which are classed under the terms "contained variability."

Functional Changes.—In a large proportion of cases the patients do not come for chest symptoms. It is only in reply to questions that they remember that they, probably months ago, spat a streak of blood, or that they have had, for perhaps a year or two, a slight throat-clearing cough in the morning. The symptoms which, in most cases, lead them to consult a medical man, are those of some form of indigestion; or often the chief complaint is expressed by, "I am always tired," "I have no strength." There is often some gradual wasting of the body; or again, amenorrhœa may be the symptom which brings the patient. Such symptoms, be they wasting, weakness, indigestion, amenorrhœa, are signs of a more general malady of the system than these terms are usually used to imply; just as phthisis itself, though known locally in the lungs, yet fundamentally is a "general" disease. It is quite a popular belief that amenorrhœa "throws" the young girl into phthisis; and it is no easy matter to impress on the patient and her mother that the amenorrhœa is but a symptom of a general vital weakness, and that it can only be restored slowly by building up the constitution by a general and long-continued, yet judicious, tonic regimen.

In the class of indigestion cases great good follows the use of arsenic combined in the form I have stated; a degree of costiveness usually co-exists; for this the patients often habitually seek relief in some popular aperient pill. This I prohibit, and prescribe a mild course of Kissengen Water (Rakocsi). Such a water taken to the amount of a wine-glassful or two at night during a period of four or six weeks, has a most restorative effect on the digestive function, and without purging; the bowels become more regular, the appetite and strength improve, the "indigestion" disappears; the arsenic and mixture is taken daily after meals during the same period. Kissengen Water contains a small amount of sulphate of magnesia, but a far larger proportion of chloride of sodium. It would open up too wide a subject here to attempt an explanation of the causes of the great curative power of natural mineral waters. Whether it be, that in their extremely complex mineral composition, they supply some "force" or "energy" to the tissues; or still further, whether their elements and atoms are combined in certain "nascent" conditions, the fact remains that they have a most potential and lasting result for good against many symptoms and diseases. The appetites of those who are in the early "verging" stage of consumption are poor and capricious; fancies for particular foods are frequent. We all know that many phthisical patients, during many years, and even from childhood, loathe fat; but it is remarkable that delicate young people, both those who are quite free from disease, and those who are in the earlier stages of phthisis, and also many who are in somewhat advanced phthisis, and who all may loathe most kinds of fat, yet often have a craving for fat pork; and further, such fat thoroughly agrees with them. It is constantly recurring in my practice such patients crave for fat pork; where craved for it agrees. I was lately consulted by a gentleman, much emaciated, in advanced phthisis, and with *fistula in ano*, who had been formerly of fine muscular development. He had consulted a physician four years before, who had strictly prohibited pork, cheese, potatoes, and suet pudding. Yet these were the very articles he craved for, and digested without inconvenience.

I continually find phthisical patients crave for onions. They eat them cooked, or raw with salt, not only without inconvenience, but with great benefit. This craving for onions is not universal, but is very general; and where it exists it is very strong. Where patients do like and eat onions, I have often noticed that a day or two after eating them the breath loses the peculiar faint smell so common, if not peculiar, to early phthisis. I find that phthisical patients eat more largely of other food, if allowed chalots or onions. Many phthisical patients crave for salted foods, such as salt fish, corned beef, bacon, &c.; when craved for, I have never known them disagree. Again, pickled onions, and other pickles, are often craved for, and agree. I very commonly find that all such articles of food are debarred the young and delicate, and those threatened with phthisis. I can most emphatically say that I see great good from their use. Phthisis is in most cases a very gradual failure of vital power, and it cannot but be of great importance to supply the system with any treatment and elements of food in those forms which each individual case may most easily digest. These cravings of patients have deep foundation in Nature's wants. Not only is their gratification important to the individual patient, but they are most suggestive towards further inquiry. These subjects may not appear highly scientific, but they are not the less important. In Nature single facts viewed in a right method may lead to wide general truths.

The long existing early vital failure, as shown in the varied functional symptoms which precede the actual appearance of tubercle in the lungs, point to wide and general relations in the body. Thus, this early vital failure directs us to fulfilling not only the just external physical conditions under which animal life can alone exist, but also to efforts at potential co-ordination of vital "energy" by the supply of the elements wanting to the system's composition, and in this latter direction the "cravings" for special articles of food have profound significance.

The benefit from the combined arsenic and hydrochloric acid treatment in a large number of cases has been so marked that I feel it a duty to lay a statement of my trials before the profession, that others may confirm or correct the practice, and perhaps arrive at a more exact prophylaxis, and a truer and wider generalisation. My aim has been to seek to prevent the development of tubercle in the lungs, in those cases in which strong hereditary or natural tendency to such growth exists; to apply

Digitized by Google

to them means, both externally hygienic, dietary, and internally by certain mineral elements, which may sustain the general vital powers of the body, and possibly the formative powers of those nerve segments of the body to which the lungs belong. The history of knowledge leads us to expect that the discovery of a prophylaxis to tubercle may be recognised, by analogy, long before mathematical analysis has determined the rate of the series of vital evolution, or before spectrum analysis shall have determined what mineral elements are wanting in the systems of those who pass to tubercle.

The history of knowledge, further, has ever shown, that the greatest general truths in Nature have been first observed in and of one series, with single facts; if, therefore, arsenic does do good; if it add to the vital power (and it undoubtedly does); if it thus, in any degree, sustains the growth of normal lung tissue, it is just to expect that in its use, in some of its forms, or in its *isomers*, may be found effectual co-ordinators of vital formative force.

Whilst I can confidently state that good results have followed the treatment in a large number of cases, yet it has failed to arrest the progress of tubercular deposit and softening, in some advanced cases, with strong hereditary tendency, in which I determinedly pursued the treatment. In some advanced cases, the patients have found themselves better, and with increased appetite, under the treatment.

Prevention becomes the great aim: in other words, during the years of youth, to avoid those varied depressing influences which lower the vital powers. I have already referred to the injury done to young people by prohibiting those articles of food which they most desire; the indoor life of our present civilisation, especially in reference to girls, injurious as it is, seems beyond the physician's power to remedy generally; but one may do great good individually. I have often been able to send out-of-doors, almost daily throughout the year, young girls who were being kept in during months, lest they should "catch cold." Such an indoor life is an almost sure road to phthisis in many cases; another very powerful depressing influence, and tending to phthisis, is that children, year after year, are sent into cold beds, and lie for hours with cold feet.

In giving arsenic, quinine, &c., during lengthened periods, to delicate young people, I have always remembered the authoritative cautions of Trousseau, as to the dangers of iron, and of rashly interfering with the constitutional habit of body of such cases; but I have not observed any contra-indications to the treatment which has been pursued.

Clinical Records.

MERCER'S HOSPITAL, DUBLIN.

Cases under the care of Mr. E. STAMER O'GRADY.

AMONGST the patients whose cases came to a conclusion during the last half of August and the month of September were the following:—

Ovariotomy—Recovery.—Patient unmarried, æt. 30, a smoker. Swelling first noticed four years ago; it began on the right side. Catamenia regular, lasting usually seven days. General health has been of late much impaired; takes but little nourishment; breath very fœtid. Renal secretion scant. The greatest circumference was 42 inches; from the umbilicus to either groin measuring 10 inches. Fluctuation very obscure; it was best marked in the upper part of the tumour. The sound showed the uterus to be free. The operation took place in a room in a small wing detached from the hospital proper, and where such cases are usually placed for and after the operation. A short incision readily exposed the cyst, which contained a very thick brown fluid; no adhesions. Pedicle clamped, and glass drainage tube inserted below it. This acted well, and was removed after 79 hours; the clamp being unscrewed after a week. For some days the prospect of the case was such as to cause considerable anxiety. Ice freely applied to the head and over the abdominal surface did good service, as also did rectal alimentation. Finally, a satisfactory and perfect recovery was obtained. It may be mentioned that during the earlier period of the treatment of this case a general and severe epidemic of erysipelas broke out in the city.

Fibroid Tumours of Uterus removed by Ecraseur and Enucleation.—The patient, æt. 34, had profuse menorrhagia for ten years. This had become much worse since her marriage, one year previously. Now enfeebled, and blanched to a degree, she sought operative interference. Digital examination found the os dilated to the size of a florin, with a polypus the size of a walnut presenting. The hand over the pelvis showed that further and more extensive trouble was present. Severe and continuous bleeding following the examination, the extirpation of the polypus was proceeded with the next day. The neck of the presenting fibroid was easily severed by an écraseur wire. After removing it, the globular-shaped extremity of another and very much larger growth was felt. The écraseur wire was applied to a somewhat narrowed portion which at first seemed to be the point of attachment of the growth; as the steel loop was tightened, and the mass drawn down, it became evident that the instrument was working in a constriction or waist-like depression in the growth, the real attachment of which was a wide insertion larger than a crown-piece into the immediate fundus. The écraseur firmly imbedded into the fibroid, enabled this to be manipulated as one wished. The steady traction exercised thereon greatly aided the shelling out, or enucleation process, which a limited incision, striking on the bed of the fibroid, enabled to be most satisfactorily practised, mainly with the right index, though the serrated scoop was of material assistance in the tougher spots. *The extremely firm grip of the écraseur facilitated greatly the extraction, or "delivery," of the mass.* Scarcely any bleeding attended or followed the operation, which was right well borne without chloroform. A good deal of febrile disturbance supervened. This abated in a few days. Later on there was lurking inflammatory trouble in the right iliac region, coincident with well marked sometime troublesome diarrhœa. After which the patient rapidly regained health and strength, being able to return to her country home 43 days after the operation. One catamenial period had occurred, the discharge being normal, both in quantity and duration.

Endometritis—Phantom Tumour.—Occurred in a well-nourished girl, æt. 17, who was also somewhat hysterical. In the abdomen was a tense firm tumour about as large as the pregnant uterus of the seventh month. In appearance and feel it closely simulated an ovarian tumour. The abdominal parietes were very thick, and masked the percussion sounds. A considerable amount of endometritis also existed. This was treated by swabbing out the canal, first with iodine paint, subsequently with concentrated nitric acid. A varied treatment, including free use of the bromide, was given internally. After a stay of nearly seven weeks, the girl left, greatly better in health, and having been for some time free from any appearance of the tumour.

Anteflexion of Uterus—Sympathetic Pain.—A well-built, healthy, florid-looking girl had suffered considerably for a long time from constant pain below the ensiform cartilage. She frequently vomited, the discharge being sometimes sanguineous. The catamenial flow was described as being preceded by, and attended with, excruciating pain. Examination showed anteflexion of the uterus; the organ was easily replaced, the reposition being attended with a feeling of immediate relief. Vomiting occurred during the manipulation, but not subsequently. During the time this woman remained under observation [including the next period, which was passed over with much less suffering than usual] she remained free from her old trouble.

Epithelioma of Lip (Three Cases).

By a curious coincidence two of these cases were instances of operation for recurrent disease. In the first

A.—The trouble was situated towards the right side of the lower lip of a man, æt. 68; was limited in extent to a portion of the thickness of the lip. Anterior and posterior elliptical incisions of less than an inch in length completely circumscribed the affected portions. The little wound was whipped together with the continuous catgut suture; it healed perfectly in a few days. This man had been operated on nine

Digitized by Google

years previously for a similar growth on the left side of the lip, where a small cicatrix is now visible.

B.—Patient æt. 70, disease towards right angle of lower lip, and recurring on the site of the former trouble, which had been operated on a year previously. On the present occasion the malady had reached to about the size of a filbert, and stretched somewhat deeply into the tissues but was dealt easily with by the ordinary V incision. Two hare-lip needles, and two carbolised catgut sutures, one at the red border, the other at the lower angle, were required to close the wound.

C.—Male, æt. 56, disease somewhat more extensive than it was in the preceding case; similarly operated on and treated. Both patients recovered nicely, and were able to leave hospital in a few days.

Epithelioma of Ear treated by Nitric Acid.—In a man, æt. 68, the right ear had been extensively affected, the lobule tragus concha and anti-tragus alone not being ulcerated, though the tissues were all more or less deeply infiltrated. The unbroken skin being duly protected with oil, fuming nitric acid was freely applied by means of a lint swab to the ulcerated surface. The process repeated every few days for three or four times caused marked improvement in the appearance of the parts. The applications were attended with but very moderate pain.

Necrosis (Two Cases).

A.—*Of Tibia.*—In a lad, æt. 16, the trouble being in the right leg, and having originated from injury in jumping a fence two years previously. A large portion of the front and lateral portions of the tibia were removed as exfoliations, or gouged away where the diseased action sank deeply into the shaft of the bones. Low down, near the ankle, and above the centre of the limb, deep fossæ had to be cleared out. Subsequent exfoliations occurred, but a considerable amount of repair became effected. The ultimate result, however, was still doubtful when the lad left for the country, three months after the operation, Though the parts were healing steadily, the probe led to diseased bone in various places.

B.—*Of Femur.*—A delicate, red-haired, strumous lad, æt. 20, the trouble being seated on posterior and lower surface of the left femur. An exploratory incision showed a large flat piece to be nearly loose. The contiguity of the joint and artery rendered it necessary to clip this into fragments before extraction. The subsequent repair was prompt and satisfactory.

Warts (Extensive) on Penis (Two Cases).

A., æt. 24, the surfaces of the entire glans and opposing prepuce being converted into one huge cauliflower-like mass. The growths were clipped and mown off by scissors and scalpel, compression at the base of the organ being maintained. The hæmorrhage, which was inclined to be very free, was effectively controlled by introducing a short catheter, and firmly bandaging the parts down by strips of lint steeped in muriate tincture of iron. In a few hours the catheter was withdrawn, but the dressing remained unchanged for a few days, when it loosened, revealing a healthy granulating surface. The patient was made an "extern."

B., æt. 21, subject of acquired phymosis, concealing a sloughing sore which bled freely, and was attended with the characteristic offensive discharge. On slitting up the inflamed and œdematous foreskin, the glans was found in state similar to what it was in the previous case, there being in addition a sloughy sore as large as a fourpenny-bit situate on the dorsum. After clipping off the warts, nitric acid was freely applied to the entire surface. In ten days the man was made an extern, the parts then healing healthily.

Ingrowing Toe-Nail (Two Cases).

A., male, æt. 28, the diseased action affecting both sides of the left great toe, the soft parts were pared freely away, so as to make oblique inclined planes on either side from the nail. Local pressure by small cylindroid pads was kept up in the subsequent dressing. A fortnight after the operation patient could walk with comfort, and left hospital.

B., æt. 22. The right great toe-nail was the seat of long-standing disease. It would have been a case well-suited for the same mode of treatment as adopted in the preceding case, but the patient insisted on the total removal of the nail, which was done by an avulser. In twelve days the parts had hardened sufficiently to enable him to leave the hospital and attend as an extern. The occupation of both these men necessitated considerable exercise and constant standing, one being a nurse, the other a waiter.

Tenotomy (Two Cases.)

A. *For Bent Knee.*—A girl, æt. 15, whose left knee had been contracted to about a right angle since she was five years old (*i.e.*, for ten years), had the joint straightened under chloroform, after section of the hamstring, and some strong fascial bonds. At first the punctures healed kindly, and the case did remarkably well, the girl being able after a few weeks to get out and go about with a parafine bandage on. Subsequently, however, diffuse suppuration of an extensive and troublesome character occurred up the thigh. This was followed by erysipelas. On recovery therefrom the girl was sent to a convalescent home, where, after nearly a month's residence, she was seized with a second attack of erysipelas. This ran a favourable course, and left the girl with a limb consolidating firmly, the toes coming to the ground, and likely to become a useful member.

B. *For Club-Foot.*—Male infant, æt. 8 months. Talipes Equino valgus; tendo Achillis divided. Case treated on a simple splint, the limb being kept in position with adhesive straps, pads, and bandages. The progress of the case was most satisfactory.

Nævoid Tumour of Upper Lip.—Male child, æt. 1; disease the size of a small filbert in the substance of the upper lip; of firm cavernous structure, producing much deformity and projection under the nose. The growth was tied subcutaneously. Subsequently, setons required to be passed through isolated portions. Suppuration eventually became established, and was persistent, continuing freely for some time after the infant's return home.

Internal Hæmorrhoids—Ligature.—In a butcher, æt. 40, one very large bunch was transfixed, and tied with stout hemp cords. The superficial portions were then cut off; very little annoyance followed. In four days the ligatures had cut through, and the patient left hospital quite well within a week.

Severe Comminuted Fracture of Leg occurred in a tall lad, æt. 16, from a slab of marble, said to weigh over a ton, toppling over on his right leg; both bones were broken in several places, and the limb was largely distended with effused blood. Well-marked and extensive synovitis occurred in the knee of the same side. The case treated in the ordinary box-splint of the hospital made a rapid and capital recovery. The patient left the hospital with a well consolidated limb 31 days after the accident.

Partial Excision—Pre-patellary Bursa.—The swelling, as big as a very large orange, covered the entire front of the right knee of a stout girl, a servant, æt. 25. A free anterior incision having exposed the sac, the integuments were dissected off it, till about three-fourths of its surface were bared, when the cyst gave way. The exposed portions were now cut off, and free vent given to a quantity of thick rice-like material. A large drainage tube, pendent at the extremities of the cut, was inserted, and the wound closed with interrupted sutures. The progress and result was satisfactory; the girl being able to leave hospital twenty-two days after the operation.

Poisoning by Paraffine Oil.—A gentleman, æt. 24, at an hotel, was given a glass of this fluid instead of brandy. The liquid was swallowed at a gulph. Emetics were promptly given. Beyond a not unreasonable perturbation, no special symptoms were observed, and the individual left hospital the morning but one after the occurrence apparently in his ordinary health.

Reduction of a Shoulder, Eight Months out.—A thin, spare, weakly man, æt. 53, a tailor, presented with a subclavicular dislocation of the right humerus. The accident had occurred eight months previously. Under chloroform, long continued extension was maintained by pulleys, and the adhesion further broken up by free movements of the limb. After various manœuvres, ultimately with the heel in the axilla, displacement was effected, and the head of the bone gotten back to its normal location, allowance being made for the filling up of the glenoid cavity. Much and constant care was necessary to keep the head of the bone in its improved position, where it was when the man left hospital fifteen days after the reduction. The utility of the limb was still considerably crippled, but the patient was well-satisfied with what had been done, and refused to allow further interference.

Complicated Double Hare-lip.—Male infant, aged 11 months, the child of a paralysed mother. Himself formerly delicate, and the subject of cutaneous trouble. The protruding inter-

Digitized by Google

maxillary mass was divided at the neck, forced back, and secured by interosseous suture. The lip, a deep one, required two needles and two carbolised catgut sutures, one of the latter being on the red border. Scarcely any blood was lost, not more than a drachm or two; the operation seemed to be well-borne, and the case looked very promising. In the evening all appeared to be doing well, but in the early morning, 17 hours after operation, the infant suddenly became convulsed, and remained so till death occurred three hours later. Save for a ravenous and insatiable appetite, this infant, at the time of the operation, seemed in every way healthy.

Excision of Elbow.—Male, æt. 24, a labourer, of notably unhealthy aspect; strumous diathesis well marked, with much glandular and suppurative mischief in the neck; also traces of former eye trouble. The elbow disease resulted from a blow of an iron bar ten years previously. The limb was extended, and numerous sinuses led down to diseased bone. On the anterior aspect of the elbow was a large ulcerated surface, which materially interfered with the after dressing. Elbow excised by the straight incision, the operation being attended with more than ordinary trouble in consequence of the dense and matted condition of the parts. Large portions of all the bones had to be removed. The limb was at first put up straight on an anterior-hinged gutter splint, which enabled it to be flexed to a right angle within a week. The progress of the case was wonderfully satisfactory; in ten days the patient was able to take regular out-door exercise. In eighteen days the splint was dispensed with; a marked improvement in the general health had now occurred. The case steadily progressed to recovery, leaving hospital with a strong useful limb and good moveable joint.

Amputation of Breast (Two Cases).

A. For scirrhus tumour, size of a small apple, on upper and outer part of gland. It had been growing a year. Slight adhesions existed to both the skin and the great pectoral. No glandular implication. Nipple not retracted. The breast and tumour removed by elliptical incision, the implicated portion of integument and a slice of the pectoral muscle being taken with the mass. The wound progressed most favourably, being healed in a fortnight. In the earlier part of the treatment free provision was made for drainage. Adequate support was carefully maintained throughout, with absorbent dressings.

B. For large adenoid tumour in a stout single woman, æt. 42. The growth was seated in the upper part of a very large breast. It had been four years growing, and was first noticed by accident. Latterly it had become very sensitive and painful on handling. The tumour and breast were removed by an inverted A meeting an elleptical incision below. Eleven vessels required ligature. The earlier progress of the case caused some anxiety; there was much increase of pulse and temperature; the margins of the cut, as well as large portions of the upper flaps, mortified. The mischief, however, was limited to where the attenuated skin had been tightly stretched over the tumour. The sloughs quickly separated, and subsequent repair was rapid, the patient leaving the hospital nineteen days after the operation, with the wound almost entirely healed.

Large Sarcomatous Tumour of Finger, occurred in a baker, æt. 41, who had the termination of his left index imbedded, a growth as big as an apple. This was in places ulcerated on the surface. By some dissection the trouble was proved to spring from the ungual phalanx, and the finger was amputated through the centre of the middle one. The little wound did kindly, and the patient left hospital at his own request in a few days, and before it had entirely healed. He seemed likely to have unimpaired power of movement over the digit. Section showed several minute cysts in the growth.

Amputation of Thigh (Two Cases).

A. On male patient, æt. 52, for disease of the lower half of the femur, sequent to former severe injury, received many years previously, which also extensively involved the knee. Before resorting to operation long and careful trial had been made of constitutional treatment. The amputation—almost trochanteric—was by long anterior and short posterior flaps. The vessels, numerous and large, were secued by carbolised catgut sutures as the operation progressed. The femur was very dense at the point of section. The case progressed satisfactorily to a speedy cure.

B. Also male, a strong, healthy labourer, who long suffered from disease of the knee, the result of injury received seventeen years previously. The joint was excised; for a couple of days the patient did well, but then spasmodic trouble became developed to an extreme degree. This was uninfluenced by treatment. The parts locally went to the bad. The patient, racked by unintermittent pain, sank rapidly, being, when the limb was amputated a week after the excision, in a truly deplorable state. The amputation was done as a *dernier ressort*, in the ward, the patient being in such a state that one darest not move him to the operation room. The steps of the procedure were as in the preceding case, the condition of the bone requiring its division at the junction of middle and upper thirds. For some days the state of the patient remained critical enough, but repair once started was rapid, and the stump was healed in a little more than three weeks. (*a*)

In both these cases pretty much the same after-treatment was resorted to. Immediate application of a solution of chloride of zinc to the wound; provision for free drainage and undisturbed rest, secured by careful strapping and position. Both men required tonic and stimulant treatment for a time.

Compound Dislocation of Ankle (Two Cases).

A.—*Amputation of Leg.*—A rearing horse fell over on a groom, a strong, healthy man, æt. 20, causing a compound comminuted fracture of the lower end of fibulæ, tearing out the peroneus longus and brevis. tendons, opening the ankle-joint, and fracturing the astragalus. The patient would not permit amputation till after he had been more than three months in hospital, during which time much local inflammatory trouble, extensively spreading up the leg, had taken place, so that it was a matter of considerable management to obtain material for "a circular" below the knee. Convalescence was somewhat slow, it being six weeks before the stump had entirely cicatrised.

B.—A wall fell on the left leg of a healthy, well-preserved man, æt. 55 (the same limb had been previously the subject of injury at the hip). There was extensive comminuted fracture of the fibulæ; and save for the ruptures of the peronei tendons the appearance of the case bore a very considerable general resemblance to what was presented in the foregoing one, the subject of which lay in the adjacent bed. The finger freely entered the joint, both anteriorly and posteriorly, everywhere meeting broken bone. The patient would not permit amputation. He seemed to suffer but little, and took nourishment freely. Nevertheless, after a few days, he began to sink. Delirium supervened; and he died eight days after the accident.

Transactions of Societies.

HARVEIAN SOCIETY.

FRIDAY, OCTOBER 17th, 1879.

The President, H. C. STEWART, Esq., in the Chair.

Mr. ALDERSON exhibited

A GREAT ENLARGEMENT OF THE HEART.

This was a heart of unusual size. It came from a young man, a cab-driver, who drove from Cambridge to London in one day within a week of his death. He had been the subject of recognised heart disease for some time before his death. A double mitral murmur was heard in life; and on the post-mortem examination, the mitral orifice was found narrowed, and also rigid, so as to permit of regurgitation. During the last few days of life convulsions, with unconsciousness were common. There was great enlargement of the ventricles, especially the left; and the aortic valves were just commencing in chronic valvulitis. The kidneys could not be examined. The heart was full of clots, and altogether weighed 38 ounces.

The PRESIDENT, Dr. WILTSHIRE, and Dr. FOTHERGILL spoke, after which,

Mr. ALDERSON replied.

(*a*) There was under treatment simultaneously with this case another, in which also amputation of the thigh had to be performed, subsequent to excision of the knee. The stump healed entirely in a fortnight, but the patient is still an inmate of the hospital, for the remains of bad bed sores.

Digitized by Google

Dr. MILNER FOTHERGILL then read the paper of the evening, on

THE IMMEDIATE AND PERMANENT TREATMENT OF DISEASE.

He pointed how in many cases the treatment which gives immediate relief is not that to be continued in the permanent interests of the patient. He instanced first the free use of opium in the hacking cough of phthisis, and in chronic bronchitis, which gave immediate relief, but did harm eventually. Then in the diarrhœa due to impacted masses in the rectum, astringent mixtures might give immediate relief, but they were not curative, while removal of the masses was. So, too, in neuralgia the injection of morphia eased the pain for the time, but if continued, was more likely to confirm it than to cure it. Likewise in dyspepsia, of reflex origin; it was all very well to give the ordinary mixture to relieve it, but its cure depended upon the removal of the exciting cause. In gout, too, the application of cold, or of leeches, give instant relief; but he quoted Garrod in illustration of the evil consequences which follow such treatment. But of all instances of the conflict betwixt the present and the permanent treatment of disease, that furnished by endocarditis was, he said, the most striking. It was the rule to give tonics as soon as possible, and to get the patient up; but, he contended, the proper plan of treatment is to keep the patient flat in bed for some days after all evidence of active mischief has passed away. The growth of connective tissue in the valve-curtains, which is lighted up by the inflammatory storm that passes over the endocardium, persists some time after the endocarditis itself is over; and it is the mutilation, caused by the contraction of the neoplasm, which we have chiefly to dread. Consequently, the true line of practice is to reduce the strain upon the inflamed valve-curtains by complete rest, and the administration of agents which lower the blood-pressure within the heart and arteries. The more the connective tissue growth could be limited at the outset, the less the future mutilation of the valves. A few days in bed are nothing compared to future valvular disease.

The PRESIDENT, Dr. CLEVELAND, Dr. MORTON, and Mr. CRIPPS LAURENCE took part in the discussion which followed, after which

Dr. FOTHERGILL replied.

The Society then adjourned.

THE NEW ORDER OF MEMBERSHIP OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

OUR readers will recollect that the College has obtained a revision of its Charter by the Government authorities, with a view to the establishment of a new order of graduates between its licentiates, or mere diploma holders and its fellows, or supreme governing body. The bye-laws and regulations in reference to membership have just been approved by the College and the Government, and are as follows:—

I.—The grade or order of members of the King and Queen's College of Physicians in Ireland is distinct from that of the fellows of the College, and the members of the body corporate of the president and fellows of the King and Queen's College of Physicians in Ireland.

II.—The members of the College alone are eligible to the fellowship. They shall have the use of the reading rooms, library and museums, subject to the regulations relating thereto, and shall be admitted to all lectures, and shall enjoy such further privileges as may from time to time be defined by the bye-laws.

III.—All persons who have been admitted licentiates of the College, before December 12th, 1878, shall be entitled to be admitted members of the College without payment or examination, on giving six weeks' notice, in writing to the registrar, of their intention to avail themselves of the privilege conferred by the supplemental charter, and on complying with all or any other prescribed conditions, provided that they have, since their admission as licentiates, obeyed the bye-laws of the College.

IV.—Every candidate for the membership of the College must be a licentiate of this College for three years at least, computed from the day on which he shall have subscribed his name on admission as a licentiate, or, a licentiate of one year's standing, and a graduate of arts of a University in the United Kingdom, or, a licentiate of one year's standing, and a registered practitioner of seven years' standing.

V.—Every candidate for membership shall furnish proof that he has attained the age of twenty-five years.

VI.—Every candidate shall produce a testimonial from a fellow or member of the College, or from a fellow of the Royal College of Physicians of London or of Edinburgh, satisfactory to the College, to the effect that as regards moral character and professional conduct he is a fit and proper person to be admitted a member of the College.

VII.—No candidate shall be admitted to examination who is engaged in trade, or who directly or indirectly vends medicines or drugs, or who practises medicine or surgery in partnership, by deed or otherwise, so long as that partnership continues.

VIII.—Every candidate for examination shall produce evidence of having attended courses of practical instruction in ophthalmology and histology; he shall also produce evidence that he has held during at least six months the office of resident physician or resident medical pupil, or has acted for the same period as clinical clerk in the medical wards of an hospital recognised by the College, or that he has been in medical charge, for at least twelve months, of any public institution for the treatment of the sick.

IX.—Every candidate, before being a member of the College, shall subscribe the following declaration in the presence of the president and fellows:—

"I do hereby solemnly and sincerely promise that I will observe and obey the statutes, bye-laws and regulations of this College, relating to members, and will submit to such penalties as may be lawfully imposed for any neglect or infringement of them."

"I further promise and declare that I will, to the best of my ability, do all things in the practice of my profession for the honour of the College and the good of the public."

EXAMINATION FOR MEMBERSHIP.

X.—Stated examinations for the membership of the College are held quarterly, in the months of January, April, July, and October.

XI.—Every candidate for the membership must return his name to the registrar of the College, and lodge with him his certificate, bank receipt of fees, and his schedule, (*a*) at least *four* days before the first Friday in each of the above-named months. Should the evidence produced by the candidate be in accordance with the bye-laws of the College, the candidate will be permitted to present himself at the ensuing examination.

XII.—Every candidate for examination will be required to translate into English a passage from a Latin author, or to show that he possesses a knowledge of Greek, or French, or German.

He will also be required to pass a professional examination in the following subjects:—Pathology, medical anatomy, histology, medical chemistry, principles of public health, including climatology and meteorology, psychology, forensic medicine, and clinical medicine. (*b*)

XIII.—The fee (*c*) for membership shall be twenty guineas.

Conditions under which Candidates who were admitted Licentiates of the College, before December 12th, 1878, may be admitted members of the College.

1. They shall comply with bye-laws IV., V., VI., and VII.

2. They shall also satisfy the College that they have, since their admission as licentiates, obeyed the bye-laws of the College.

3. They shall give notice, in writing, to the registrar, of their intention to avail themselves of the privilege.

4. Should the College be satisfied that they have complied with the above regulations, they shall be admitted

(*a*) Blank schedules are to be obtained on application at the College, or by letter addressed to the registrar, College Hall, Kildare Street, Dublin.

(*b*) The examination will be conducted by printed questions, and orally, as well as at the bed-side in the medical wards of one of the hospitals.

(*c*) This fee must be lodged to the credit of the King and Queen's College of Physicians in Ireland, in the Royal Bank, Foster Place. All cheques made payable to the Treasurer, to be crossed Royal Bank.

Digitized by Google

members without fee or examination, on taking the declaration required of members. (a)

Should the candidate wish to obtain the parchment diploma of member, he shall pay one guinea.

(Signed),

J. MAGEE FINNY, M.D., Dub.,
October 15, 1879. Fellow and Registrar.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 22, 1879.

THE RELATION OF THE STATE TO MEDICAL EDUCATION.—III.

IT is, in fact, the inequalities of the existing system of medical licensing in this respect which has caused it to break down, and has necessitated the erection of a uniform standard of educational competency, upon which the Government and Parliament are now engaged. The higher class of licensing bodies, as for instance, the English Universities, and the University of Dublin, occupying a position of monetary independence, have been enabled to give effect to their desire that their *alumni* should be men of culture and of the highest qualification, and have demanded from candidates an extent of study, a degree of knowledge, and an expenditure of money, which could only be repaid to the student by the lucrative practice of cities or by the highest public appointments. These bodies, in fact, lay themselves out to supply a limited and high-class medical market, and they do not pretend that their degrees are qualifications suited to the wants of the profession at large or of the great mass of the community.

On the other hand, certain of the licensing bodies, being coerced by the struggle for existence, have offered their diplomas to all comers who could bring their diploma fee in their hand and support a pretence of professional competency by a smattering of medical knowledge. These bodies supply the lowest medical market with a qualification below even its needs, and do not aim at any higher function than guaranteeing enough medical knowledge to enable the practitioner to pass muster. The high-class body undoubtedly does its duty, by requiring strict proof of the capability of those whom it qualifies, but it cannot be said, in any degree, to fulfil its function of supplying the public with medical practitioners suitable for their use. The low-class corporation is guilty in many demonstrable instances of sending out into the world men utterly unfit to undertake the treatment of the most ordinary diseases, and, in fact, dangerous to the lives and health of the community.

Yet the degree of the high-class bodies occupies legally, exactly the same position as the nominal guarantee given by the low-class corporation, and neither institution fulfils the duty which the public expects from it—that of supplying for the public use practitioners thoroughly competent to take charge of patients, and at the same time willing to work for the remuneration which the community at large can offer.

As long as the supply of practitioners is not over-restricted, and that the public suffers no inconvenience by the over-education of medical practitioners, it is obvious that the State has no reason to interfere in the regulation of high-class licenses, inasmuch as they are all sufficient as guarantees of competency, and are requisite for the wants of the more wealthy of the community. But the amount of education suited to the requirements of the lower classes of the community cannot be left solely to the limitation of the law of demand and supply; and, inasmuch as the Medical Council have failed in imposing a proper educational limit, it has become the duty of the State to interfere.

For these reasons it must be borne in mind by the framers of the schemes of conjoint examination, which are to be the entrance gates of our profession in the future, that it will be their duty to insist upon nothing more than reasonable practical competency to treat every-day disease and to grapple with surgical emergencies of ordinary occurrence. This, and nothing more, should be the definition of professional efficiency, as demanded by the State; and it will require discretion to frame such a scheme of education and examination as shall mark that limit at its proper position in the medico-educational scale. We are all conscious that there is really no such entity as perfect and comprehensive medical and surgical capability, and that whatever degree of education we may demand, it will always fall short of that which is required to deal with occasional emergencies. We must, therefore, place restraint upon our desire—the offspring of this consciousness—to force upon all practitioners the acquirement of skill suitable to these exceptional emergencies, and we must not lose sight of the fact that the community at large neither needs nor is capable of paying for such attainments, and that, generally speaking, the patient has facilities for obtaining the benefits of this high degree of skill when it is urgently needed.

(a) In case the residence of any candidate should be out of Ireland, the candidate will be required to send a copy of the declaration, written in his own handwriting, with his name subscribed and duly attested.

Digitized by Google

We would, therefore, urge that in the construction of conjoint schemes of education and examination all considerations—scientific and social—should yield before the superior claims of the practical, and that it should be constantly before the mind of the framers of our future system that thorough competency, such as can be achieved under all the existing circumstances, can be best secured by insisting that the student shall have learned thoroughly the groundwork of his daily average practice, and that he shall prove by actual demonstration that he knows how to use that groundwork to his patient's advantage.

In connection with conjoint examination we, therefore, deprecate the dilution of the education or examination by high science, advanced theory, or literary erudition. Had we the dictating of the system, we should ask nothing more and accept nothing less from the student than a thorough knowledge of the anatomy of the viscera, and of all those parts that meet the eye in surgery, or the mind in practice of physic; a knowledge of physiology thoroughly sufficient for the comprehension of disease as it is seen and felt in every-day practice; a full acquaintance with the chemical and physical relations of the animal functions; a perfect understanding of the principles—mechanical and pathological—upon which surgery is founded, and a knowledge of the therapeutic effects of drugs in their various combinations.

All knowledge beyond this—advanced chemistry, pharmacy, hygiene, botany, forensic medicine, comparative anatomy, and so forth—I would encourage and reward, but not demand. Finally, I would insist that every candidate for admission to the profession should prove the thorough competency of his mind, his senses, and his fingers to apply the knowledge thus tested to his practice. He should prove his quality upon the sick patient, the dead subject, and the model, with knife, bandage, splint, stethoscope, and test glasses. He should show me that, unaided, he was capable of examining a patient, diagnosing the disease, and attacking it with hand and with drugs. Beyond this—for a qualifying examination—we would not go one step, and would to relegate Fellowships and Doctorates a knowledge of all those theoretic investigations and literary crudities which form, under the present system, no insignificant part of the student's work.

Should the method which we advocate be pursued, we may, possibly, have uncultured and ill-read practitioners, but we will, at least, not be chargeable with receiving into the ranks of our profession and letting loose into general practice men who have never acquired, or been asked to acquire, the commonest elements of medical theory, the most moderate knowledge of animal structure, or even a limited acquaintance with disease or its treatment.

THE ADMINISTRATION OF THE PUBLIC HEALTH ACT IN IRELAND.

We have already devoted two articles, published since the issue by the Irish Local Government Board of the sealed order with reference to the appointment of medical officers of health, to the purpose of pointing out that the tendency, and, apparently, the object, of the Board is still, as it has always been, to neutralise the intention of the Public Health Act in Ireland, and to discourage sanitary activity on the part either of local authorities or their officers. We protested most earnestly—and we reiterate the protest now—against any public department undertaking to change the policy of Parliament, and, by manœuvring the limited powers confided to them, to defeat the purpose of the law which is entrusted to their administration, and we cannot refrain from giving expression to our surprise and disgust that the Local Government Board for Ireland should, through many years, have accepted and continuously occupied the position of the enemy of sanitary improvement. It is not necessary that we should repeat our references to the evidence that the Board has deliberately assumed and maintained this attitude; we propose now to appeal to history to show that the admitted break-down of the Irish public health system is the natural outcome of this policy.

We have already narrated how the Irish Local Government Board initiated its obstruction by illegally abolishing the office of Medical Superintendent Officer of Health, which was created by the Act of 1879, and by illegally creating the sham appointment of Consulting Sanitary Officer, for which there is not, and never was, any authority in the law. We have reminded our readers that their second step was, under the cloak of the Treasury, to forbid sanitary authorities to give anything like an adequate salary for sanitary duties. When these salaries came to be fixed the boards of guardians were utterly ignorant as to the nature or extent of the duties to be performed, and sought information from the Local Government Board. That department did not afford the information, but replied, in effect, that the sanitary authorities might vote a nominal salary for the time being, and increase it when they pleased. Doubtless the L. G. B. knew quite well that the authorities would *not* please, and served their own purpose by inducing such authorities to fix sham salaries as a temporary measure, being pretty certain that the said sham salaries would, in many instances, be permanent. Therefore, very many of the medical officers undertook their public health duties on salaries of £3, £5, or £10 a-year, and never got beyond that noble scale of remuneration.

Thus, the execution of the sanitary law of Ireland began under not very encouraging circumstances—its administrators themselves often the worst offenders against sanitation, and educated for all their lives in dirt and sanitary neglect. Its officers, new to their work, and uninstructed as to their duties, paid next to nothing, required to discharge functions which they knew would be inglorious, uncomfortable, and unpopular; its governing department anxious that both the local authorities and their officers should do as little as possible, and give as little trouble as might be by overzeal. Of such a state of things the natural and inevitable tendency would be that the officers would speedily learn that it was "the buttered side of their bread" to take their salaries and do as little as possible, and leave sanitation to take care of itself. That such results did not actually accrue was proved by the Parliamentary returns made on the 21st of March, 1878, upon the motion of Mr. O'Leary, M.P. This document gives the number of sanitary reports made

Digitized by Google

by each sanitary officer in Ireland for the successive years 1875, 1876, and 1877. We have taken pages of this return at random, totted the numbers of reports made by 250 officers named on these pages, and calculated out the proportional numbers for the whole of Ireland. The result is as follows :—

Number of reports made by 802 sanitary medical officers—

1875	25,479
1876	11,159
1877	9,011

It will thus be observed that on an average each medical sanitary officer made, in the first year of his appointment—

1875	32 reports.
1876	14 ,,
1877	11 ,,

There was, in fact, a falling off of sanitary zeal in each successive year, as compared with its predecessor : for

1876	56 per cent.
1877	13 ,,

It is obvious that the number of inspections recorded in this return could have had no appreciable effect upon the amount of insanitation existing in Ireland, and we must, therefore, conclude from these figures that, in consequence of the discouragement administered to their officers by the sanitary authorities and the Local Government Board for Ireland, nearly three-fourths of the work which the Public Health Act provided for ceased to be performed, and that, since that time the sanitation of Ireland has remained, to all intents and purposes, absolutely neglected. We appeal to these figures as proof beyond dispute, that the Dispensary and Workhouses Medical officers of Ireland were always ready, anxious, and competent to carry into execution the sanitary law of Ireland, that, in spite of such readiness that law has ceased to operate, and, we insist that for that failure, the Local Government Board for Ireland, and it alone, is directly answerable.

Having, as we have said, opposed and hindered the sanitary officers in the performance of their duty, the local authorities and the Local Government Board, have not hesitated to make use of that failure of efficiency, for the purpose of still further discouraging sanitary reform. On the recent readjustment of salaries, the sanitary authorities have, one and all, made use of the argument that, as little or no work was done, they were justified in decreasing the pittance hitherto paid for the performance of such work. Not one Board of Guardians in Ireland, so far as we have seen, has realised the fact, that it has had, in return for the sum which, if paid, much more than its value in labour, nor has the Local G. B. had wit enough to see that, the more they reduce the salaries the less work they will get out of the dispensary medical officers, and that they themselves are solely to blame in the matter. There must be no misapprehension on this point. Parliament has thought fit to force certain duties on a certain class of professional men, without their having sought for the functions. That class of officers have accepted the duties without protest, and have, *pro tanto*, made themselves liable to perform the duty efficiently as long as their employers observe their part of the contract. But an item in that contract is that the employers shall pay a fair remuneration for the work to be done ; and if they have failed to do so, neither Parliament nor the Local G. B., nor the sanitary authorities, have any moral right, nor can they have any power, to compel these officers to perform the duties efficiently. We feel ourselves morally justified, and fully authorised, to tell the Local Government Board that they will obtain from the health officers of Ireland what they pay for only, and no more ; and that they have no reason to expect, from their recent proceedings, any other result than a sham execution of Irish sanitary law, and ultimately a disgraceful and disastrous breakdown, and a thorough public exposure.

Notes on Current Topics.

Changes in the Profession in Ireland.

In the compilation of the Irish Medical Directory fo the forthcoming year, in addition to several thousands of changes in appointments, &c., the names of 310 members of the profession will have to be removed from the last issue, 54 of these have died since the 1st January last, and 256 have left Ireland. During the same period 135 members have been either registered, or have settled to practice in Ireland, 126 have changed their addresses to other parts of Ireland ; these returns show the need for such a publication. The edition for 1880 will contain above 2,550 names, and amongst the list of distinguished members, the new issue will contain the names and particulars of those members of the profession who are holders of the Victoria Cross.

Registration.

In our advertising columns to-day, will be found a notice which is very important to many of our readers. It is often forgotten that by Section xiv. of the Medical Act, qualified practitioners are liable to have their names erased from the official Register, and thus, by Sections xxxi. to xxxvii. of the said Act, to lose the right to hold certain appointments, to sign valid certificates, or to recover in any court of law charges for professional services. For their own interests, therefore, we would counsel all who have changed their residence since registration or whose names or addresses appear incorrectly in the present edition of "The Medical Register," to at once send a rectification thereof, to the Registrar, in order to avoid the annoyance and inconvenience that would necessarily follow omissions or inaccuracies, for which they alone are responsible.

The will of the late Dr. Radclyffe Hall, who formerly practised at Torquay, Devon, has just been proved, and the personal estate sworn under £90,000.

The German Medical Congress at Eisenach has declared vivisection necessary in the interests of science in general and of medicine in particular.

The Wisdom of Guardians.

THE inmates of the Bethnal Green Workhouse are at present suffering under the infliction of guardian-wise regulations, which are likely, if persisted in, to eventuate in a serious epidemic of disease. By a decision of the guardians of the Bethnal Green Parish, a well has been recently opened in the grounds of the workhouse, and from it the paupers have been, and are still, supplied with drinking water. By analysis of the liquid, Dr. Frankland has arrived at the conclusion that it is distinctly poisonous, and in spite of this the authorities continue to insist on the use of the deleterious water by the eleven hundred inmates of the union. In face of the expressed opinion both of Dr. Frankland, and one at least of the guardians sitting on the board, this determination cannot be regarded in any other light than as a direct negligence on the part of the members who concur in the act of the majority; and further, it must be thought that any ill effects, such as may be confidentally expected to follow continuous ingestion of a noxious element, will be the effect of a culpable disregard of public duties by public servants. Surely, however, the medical officer of the union can exert a sufficient amount of authority to stop the further consequences that must follow should the guardians, after due warning, persist in the decision they have already expressed.

Railway Comforts.

THE Great Northern Railway Company has just commenced a train service which will be a means of adding much to the comforts of those who require to take frequent and hurried journeys by train. One of the chief discomforts of the present system—a discomfort productive of very considerable digestive disturbance—is the inadequate accommodation for feeding afforded by the refreshment rooms of most stations. Further, too, the hurried bolting of the food to which passengers are forced is the cause of many an attack that follows after journies by rail. The introduction of a saloon dining car, therefore, on the Great Northern line to Leeds will be hailed with satisfaction by business men, to whom time and health are valuable. If they should become sufficiently generally employed on our lines to lead to the closure of the ordinary refreshment room, then will be destroyed one source, at least, of very much of the casual illness of this country.

Dr. Bristowe on Preventive Medicine.

THE inaugural address on the opening of the new session of the Society of Medical Officers of Health was delivered on Thursday last by Dr. Bristowe. In the course of his speech he dwelt on the great importance of studying the progress of preventive disease, with the object of introducing methods whereby its course may be obstructed at an early stage; and he expressed an opinion that the rapid strides made, and being made, in pathological knowledge, must result in a very extended field for the application of the expectant treatment. A hopeful view was to be taken of the endemic diseases, such as goître, cretinism, dysentery, and malarious fevers, and though the exact cause of them may be at present unknown, daily progress was being made in the way of ascertaining facts that would lead to a rational ætiology. As an indication of the points necessary to be followed out, and as sketching the modes of procedure to be adopted by observers, the address possesses a distinctive value; and since it will be printed and circulated by the society before which it was delivered, it will probably be serviceable by stimulating medical officers of health to enter on a more searching inquiry into the causes and possible prevention of disease.

The Howard Medal.

THE Statistical Society announces that the Howard Medal, to be awarded in November, 1880, will be for the best essay on "The Oriental Plague in its Social, Economical, Political, and International Relations, especial reference being made to the labours of Howard on the subject." In addition to the medal the winner will receive a money grant of £20 from the Council of the Society. Papers must be sent in to the house of the Society on or before June 30th, 1880.

An Interesting Surgical Case.

WE extract the following note from *Nature*:—

"An interesting surgical case was recently reported by M. Larrey to the French Academy of Medicine. A young carpenter received a blow from an axe on his right foot. The big toe was almost completely detached; it was held merely by a small shred of skin, and hung on by the side of the foot. Dr. Gavey, who was at once called in, detached the toe completely; then after having washed it, and the wound on the foot, he adapted the two surfaces as well as possible, one to the other, and made them hold together by means of strips of lint soaked with collodion, and placed along the toe. When the collodion had set, another strip was wound round. Further, an apparatus was used to keep all the parts of the foot in perfect immobility. Twelve days after the dressing gave no bad smell, the patient was very well, and desired to go out; and twenty-four days after the accident the cicatrisation was perfect."

It is to be regretted that no mention is made in the above record of the dressing employed in treating the case. From the account given, however, we infer that antiseptic precautions were employed, though possibly from the nature of the injury, and the immediate attention it received, it may have done thus well under the older plan.

The Italian Colony in London.

A SPECIAL commission deputed by the *Lancet* to report on the condition of the Italian colony on Saffron Hill, has recently issued an account of its investigations. From the description there given it is abundantly clear that very energetic measures of sanitary reform must be speedily adopted to prevent the neighbourhood from becoming a hot-bed of epidemic disease. In every house in the quarter, overcrowding is practised to an extent unusual in even the most thickly populated English regions, very many of the rooms inspected being so filled with inmates during the night that there was as little as fifty or sixty cubic feet of air to each person; and in no instance was it found that anything approaching the amount of cubic space necessary to health was enjoyed by those sleeping in the rooms. The surroundings, too, were of the most disgusting description. The accumulated filth of years lay everywhere

Digitized by Google

around, in defiance of all hygienic law, and the natural concomitants of such neglect, vermin and noisome effluvia, were apparent to eye and nose often to an extent unbearable to any but the accustomed senses of the organ-grinder. The common rules of decency, too, were violated, by the huddling together of both sexes indiscriminately in a single apartment, no regard being made either to family relations or the fact of no family ties at all connecting the inmates. The utter ignorance of the dangers attending them through the presence in their midst of persons suffering from infectious disorders, shown by these people, and pointed out in the report, presents, in our opinion, the gravest indications of a possible spread of disease through the agency of the peripatetic street musicians; and it becomes a matter of some moment to the public of London, and of those other large towns where similar colonies of Italian emigrants exist, to adopt prompt and efficient means of ensuring that the dangers to be apprehended from this source shall be as limited as they possibly can be. The attention of the sanitary authorities will doubtless be d awn to the nuisance now that it has been thoroughly exposed, and habits of cleanliness, and precautions against the risks of infection, however uncongenial to them, will be forced on the unwilling foreigners who locate themselves in the midst of crowded districts.

Aristotle's Theory concerning Right-Handedness.

Dr. Crichton Browne has lately been lecturing on the subject of "Right-handedness," thus reviving a topic which has not been overlooked by the ancients.

Aristotle has written on the subject, and Mr. Pearson, of Emmanual College, Cambridge, contributed a paper to the Cambridge Philosophical Society, 1874, on "Aristotle's Notions of Right-handedness." The following synopsis of Mr. Pearson's paper, read by the light of Dr. Browne's more recent theories, will be interesting to all who have read Dr. Browne's lecture. After referring to the paper by Dr. Hollis on this subject, communicated ast year (Nov. 30, 1874, *Journal of Anatomy and Physiology*, vol. ix., p. 263), Mr. Pearson stated that he had been led by Aristotle's great reputation to inquire what his views on the subject might have been.

Partly from a perusal of much that Aristotle has written on the subject, but mainly from the new index by Prof. Bonitz, he gave a *resumé* of the passages bearing on the subject. These passages seemed to show that Aristotle considered (1) that the right hand or side was naturally the source or origin of motion; (2) that in nearly all living creatures capable of motion it is the better or stronger side; (3) but that while the heart is always the origin of vitality, it is in the human race only set towards the left side of the body; in all other living creatures it is in the centre of the body or trunk. And though it may be a fair question how far Aristotle was misled by the preferential use of the right hand by the human race, to attribute an excellence in the right side to the animal world, there can be no mistake about the distinct language in which he does so. Some observations were added about terms in which Mr. Lewes in his work on Aristotle (1864), criticises some errors into which that writer has fallen in his works on natural history, while it was admitted that he is probably right in considering that there is no reference in Aristotle's writings to the anatomical examinations of any but animal subjects; though the fact that Macrobius ascribes to Erasistratus and Herophilus—two celebrated physicians of the succeeding generations—the practice not only of dissection, but of vivisection of human bodies, it shows that if the story be true, public opinion could not have been quite unprepared for it.

Mr. Pearson also refers to a passage in the Encyc. Britann., art. "Com. Anatomy" (202-205, ed. 1810, but not occurring in later editions), in which the preferential use of the right hand is discussed and ascribed to a natural peculiarity in the form of the subclavian and carotid arteries on that side, in which it is stated that a similar preference for the right side may be traced in dogs, if not in horses.

He said, however, that he would not answer for the existence of such a preference himself in those animals, nor in the lion and camel, to which Aristotle and Pliny after him especially ascribe it. He concluded by exhibiting a lobster, of which the right claw is distinctly larger and stronger than the left, as is especially mentioned by Aristotle.

In the subsequent discussion, Mr. Neville Goodman considered that the paper had only shown the superiority of the inductive to the speculative method of reasoning, although proving Aristotle's skill in adducing facts from the great repertory of Nature in favour of his own views.

He quite admitted that many facts indicate the right side as having a preferential motor function. In addition to the examples given, the whole order of Gasteropods were mentioned as having their chief organs on the same side, while the ordinary snail exhibits an excessive development in the same direction. To this rule, however, there are many exceptions. Again, the flat fish (*Pleurovectidæ*), though quite asymmetrical in their form, have not by any means always their motor functions to the right, the sole being generally developed to the right, the turbot to the left. He doubted the preferential use of the right side in animals, and though in ancient art the left leg is advanced, the position he thought purely conventional.

The Health of Dublin.

The deaths registered in the Dublin Registration District during the week ending October 11, 1879, represent an annual mortality of 28·8 in every 1,000 of the population. The average annual death-rate represented by the deaths registered in eight large town districts of Ireland (including Dublin), last week was 23·5. In London the death-rate was 19·7; in Glasgow it was 18·0; and in Edinburgh, 18·9.

In the Dublin district the deaths amounted to 174. The number of deaths from zymotic diseases registered is 27, being 9 under the average for the corresponding week of the last ten years: the deaths in this class include 2 from small-pox, 3 from measles, 9 from scarlatina, 1 from whooping-cough, 5 from fever (1 typhus, 3 enteric, and 1 simple continued fever), 4 from diarrhœa, &c. The registered deaths from small-pox are 3 less than in the preceding week, and are much under the average of recent weekly numbers, but the admissions to hospital of new cases of

Digitized by Google

this disease, which have of late fluctuated considerably, were, last week, in excess of those for either of the two weeks preceding, the number being 36 against 17 in the week ending 4th inst., and 28 in that ending 27th ult.; in the week ending September 20, 42 new cases were admitted. Twenty-one patients were discharged last week, 4 died, and 80 remained under treatment on Saturday last, being 11 over the number in hospital at the close of the previous week.

The number of new cases of scarlatina admitted into the principal Dublin hospitals last week was 10, against 19 in the previous week, and 6 in that ending 27th ult. But few cases of fever or of pneumonia were admitted.

The quarterly summary just issued of the number of deaths in the district during the quarter ended September 27 amounted to 1,970, affording an annual ratio of 25·0 in every 1,000 of the population. The average number in the third quarter of the ten years 1869-78 was 1,724, equivalent to an annual mortality of 22·0 per 1,000 persons. Thus the deaths during the past quarter show an excess of 246, or 14 per cent., over the average of the corresponding quarters of the past ten years, and a rate of mortality in excess of that average amounting to 3·0 per 1,000.

The ratio for London during the quarter was 18·4 in every 1,000 of the inhabitants; in Glasgow, 16·9; and in Edinburgh, 16·5 in every 1,000 of the estimated population.

The number of deaths from zymotic diseases registered during the quarter was 383, being 138 less than in the second quarter of the current year, and 47 under the average for the third quarter of the past ten years. The deaths from this class were at the rate of 4·9 per 1,000, against an average of 5·5 per 1,000. Omitting deaths of persons admitted into Dublin hospitals from localities outside the district, these seven principal zymotic diseases caused 289 deaths, being equivalent to an annual mortality of 3·7 per 1,000. These deaths consisted of 60 from small-pox, 29 from measles, and 68 from scarlatina.

In the deaths registered from the seven principal zymotics there has been a decrease of 60 in small-pox, 31 in measles, 14 in scarlatina, 2 in diptheria, 7 in whooping-cough, and 18 in fever, and an increase of 17 in diarrhœa, as compared with the second quarter.

During the quarter there were 261 cases of small-pox admitted to the Dublin hospitals, against 462 in the preceding quarter. At the close of the quarter, on September 27, there were 80 cases of this disease under treatment, as compared with 93 at the close of the second quarter, on June 28. Towards the end of the quarter small-pox showed a tendency to become more prevalent in the Dublin district; the lowest number of weekly admissions to the hospitals was 5 in the fifth week of the quarter, and the highest, 42 in the twelfth week, and 28 cases were admitted during the thirteenth week.

Diseases of the respiratory organs (exclusive of phthisis) caused 308 deaths, being 118 in excess of the average for the third quarter of ten years, but showing a diminution of 299 as compared with the preceding quarter.

The annual rates represented by the deaths from all causes in the several registrars' districts range from 14·4 per 1,000 inhabitants in Rathmines to 33·1 in No. 1 South City (Meath Street) district. There were no deaths from small-pox for any of the suburban districts except Rathmines, to which 3 are chargeable; they were registered in the weeks ending September 6 and 13. There were no deaths from measles in the suburbs. Two deaths from scarlatina occurred in Kingstown, and 1 each in Rathmines, Donnybrook, and Blackrock. Diphtheria caused 1 death in Kingstown, but none in the other suburban districts. There were no deaths from whooping-cough in the suburban districts. The total death-rate for the city was 26·3 (27·2 on the north side, and 25·5 on the south), and for the suburbs 16·7 per 1,000 inhabitants.

The respective annual death-rates represented by the deaths registered during the quarter, in the seven provincial town districts included in the weekly returns are:—Belfast, 22 per 1,000 of the population; Cork, 22 per 1,000; Limerick, 22; Londonderry, 17; Waterford, 18; Galway, 15; and Sligo 14 per 1,000.

In Belfast the annual rate presented by the deaths from the seven principal zymotic diseases registered during the quarter was 3·4 per 1,000; in Cork the rate was 3·0; in Limerick, 1·5; in Londonderry, 1·0; in Waterford, 0·5; in Galway, 0·8; and in Sligo, 1·6. Whooping-cough caused 53 deaths in Belfast, where the disease has been prevalent during the last nine months, and 44 of the 497 deaths registered in Cork resulted from scarlatina, the disease being most prevalent in No. 7 (south-west, or Bishopstown) district.

Tetanus following Vaccination.

The question of the danger of vaccination has been frequently discussed, as well as the best and most reliable methods of performing this simple but all-important surgical operation. Dr. Ross in the *Southern Clinic* reports the following important case of death due to unclean vaccination:—

Edward K., three-and-a-half years old, of healthy German parentage, never sick since a mild attack of scarlatina in early infancy, was visited at eight o'clock p.m., June 5th, 1879, and found to be suffering with tetanus, from which he died before 8 a.m. the following morning. He had no evidence of having, either recently or remotely, received an injury of any sort—no wound by puncture, laceration, or incision at any time since birth, with the exception to be mentioned. It was only during the early part of the day that his family noticed a peculiar expression about his face, and an occasional elevation of his arms and shoulders, which culminated at dinner in a pronounced convulsion. The jaws were tightly locked, and as night advanced, spasms recurred with rapidly increasing frequency, and only ended with his death. Three weeks previous to his attack, he had been *vaccinated* by a German midwife, the virus inserted in two points on the left arm. Upon one of these sites, a normal looking, almost dry crust appeared, and at the other a *highly inflamed ulcer*, from which the crust had evidently been forcibly torn.

We have always strongly condemned and deprecated vaccination being performed by any other than a skilled professional medical man, who conscientiously exercises as much care in this as in the performance of any of the major operations. Until late years in this country it was too common an occurrence for children to be vaccinated

Digitized by Google

by some midwife or woman popularly credited with the possession of medical skill and knowledge. In this case presumably the instrument employed—probably a rusty needle—contributed materially to the fatal result that ensued.

Elastic Caustic.

An elastic pencil of lunar caustic may be prepared by dipping a laminaria tent, two millimetres in diameter, into tolerably thick mucilage, and then rolling it in finely-powdered nitrate of silver. After drying, an elastic pencil, the size of the ordinary slate, remains, which may be readily introduced into the uterine or other cavity without fear of fracture. The above method of cauterising the cervix and interior of the uterus will be found of ready service and of extreme value by those engaged in gynæcological practice.

The Sins of Tobacco.

At the annual meeting of the British Medical Association at Cork, in the sub-section of ophthalmology, tobacco was seriously impunged, as being the cause of a form of amblyopia, and in the *Contemporary Review* Dr. Richardson further accuses tobacco of very serious effects. He says: "Amongst those who are total abstainers from alcohol few were found who could bear tobacco in the most moderate use of it. Under tobacco the heart seems rapidly to run down in power, and alcohol is called for, to whip it up again, also as it seems.....A few abstainers smoke tobacco, but as the habit seriously taxes their physical health, most of them in due time forego the luxury of the weed as soon as they discover its injuriousness."

We were under the impression that abstainers were large smokers; from our own observations amongst teetotal friends we find that the weed is a favourite luxury. Moreover, the use of tobacco is common in countries, such as Turkey, where alcohol is not habitually used. We do not know that any serious effects have resulted from aught but its excessive indulgence. We require, therefore, some further evidence before accepting the dictum of Dr. Richardson, or advising our smoking readers to entirely abandon those habits which have called forth such an impeachment.

Siderodromophobia.

In a late number of the *Medical and Surgical Reporter* of Philadelphia, is a brief notice of a new form of disease, described by Dr. Rigler, a German railway surgeon, to which he has applied the above name. This is a form of intense spinal irritation, coupled with a hysterical condition, and morbid disinclination for work, which is the result of shock, and occurs among railroad men; most commonly seen in cases of railway-engine mechanics who have some altered nerve condition, or irritation of the nerve-centres. It is the perpetual jarring, shaking, and noise which lead by degrees to this change, and which under the influence of some unexpected shock completely breaks up the nervous equilibrium.

This form of nervous disorder is particularly interesting as often preceding the most intractable cases of inebriety. It is the experience of every one acquainted with the clinical history of inebriates, that railroad men, of all other classes, present a combination of special symptoms, consisting of convulsions and paralysis, when they become inebriates. Alcohol seems to unmask and bring to light the results of nerve irritation and strain so common among railroad men. Probably no class are more subject to inebriety, as a result of their irregular life, and the constant strain and exhaustion to which they are subject. Many railroad men feel a craving for alcohol or its compounds which, for a long time, they are able to control; others give way precipitately to it. In all cases it is a clear hint of exhaustion of the nerve-centres, demanding rest and relief. Alcohol is found to paralyse this want, or obliterate it temporarily, hence it is used.

Stimulants in Workhouses.

Apropos of the report of Dr. Webster respecting his experience in the use of stimulants in St. George's Workhouse, London (which report has been used throughout Ireland by the temperance party, and has produced a decided effect), we think it right to print an opinion which seems to us to bear much good sense. Miss Stephen, well known for the attention which she has given for many years to visiting workhouses, writes concerning the infirm women's ward of St. George's Union, that the cutting off of the daily half-pint of beer at the workhouse by the medical officer in carrying out his rule for the abolition of the use of alcohol, has been severely felt by the old women, who were making the best of the hard end of a hard life, inasmuch as neither soup nor coffee is substituted, and the dinner is unaccompanied by any comforting drink. She thinks it a pity that this experiment in teetotalism should be tried on these poor old women.

We are very sceptical that there is anything virtuous n stopping the daily beer of poor old decrepit paupers, who are not philanthropic enough to appreciate the advantages of total abstention.

Exporting Diseased Sheep from Ireland.

At the Ballinasloe Sessions last week, a Mr. Lambert sought the recovery of £50, value of twenty-seven sheep, from Patrick Finn, which were said to be sound, yet died from disease in November, 1878. A man named Ruane swore he brought some of the sheep from Mr. Lambert as rotten sheep, and exported them to Liverpool. Witness said he often put a few rotten sheep among sound ones when sending to Liverpool. Rotten sheep paid sometimes better than sound ones.

The Queen's University and the British Medical Association.

At a meeting of the Senate of the Queen's University in Ireland, held in St. Patrick's Hall, Dublin Castle, on Wednesday last, the degree of M.D. *honoris causâ* was conferred by the Chancellor of the University, His Grace the Duke of Leinster, on Dr. Denis Charles O'Connor, President of the British Medical Association; and, *in absentiâ*, on Dr. Randle Wilbraham Falconer, ex-President of the Association, in recognition of the late annual meeting of the Association in Cork, one of the University's College towns. The honorary degree of Master in Surgery

Digitized by Google

was also conferred on the same occasion on Mr. William MacCormac of St. Thomas's Hospital, and a distinguished *alumnus* of the Queen's University, in recognition of his services as chief of the Anglo-American Ambulance during the Franco-Prussian War, and of his eminence in his profession.

The Medical Society of London.

THIS, the oldest of the medical societies of London, opened its 107th Session on Monday, with an address by the President, Dr. Cockle. Amongst the remarkable works in the possession of the Society is the picture which surmounts the Presidential Chair, a picture believed to be painted by Copley, illustrating the famous Dr. Lettsom presenting the deeds of some property in Bolt Court, Fleet Street, to the society in 1775. The figures are all portraits, including the only known one of Dr. Jenner, together with those of Dr. Sims, Sir John Hayes, Babington, and others. The picture is often consulted by antiquarians, and is of much historical interest.

Deaths from Chloroform.

ON Monday week an inquest was held at Ashton-under-Lyne, by the district coroner, on the body of a young lady named Mary Handford. The deceased had been suffering from a tumour upon her breast, and by the advice of her medical attendants, Dr. Gardiner and Mr. E. Lund, professor of surgery at Owens College, Manchester, she consented to have it removed. The two gentlemen named attended at her house on Saturday for this purpose, and Dr. Gardiner administered the chloroform by means of an inhaler. She had inhaled the anæsthetic for only about two minutes, and had not passed into the second stage of narcosis when her pulse became feeble and she died. Both medical men had previously given it as their opinion that she was a fit subject to receive chloroform. The verdict was one of "death by misadventure."

On Wednesday week Dr. Hardwicke held an inquiry at Tottenham Court Road as to the death of Harry Knowlton, aged six years, son of a smith, who died in University College Hospital, while under the influence of chloroform. For two years past he had been under treatment in different hospitals for contraction of the sinews of the legs. On Thursday, Mr. Marshall, the senior surgeon, performed an operation on him, and the next day it was decided that splints should be placed on his legs. Chloroform was given to the child, and he was about to be operated on when it was noticed that he had ceased to breathe. Artificial respiration was resorted to, but without success. The jury returned a verdict of "death from misadventure."

King and Queen's College of Physicians in Ireland.

AT the annual stated meeting of the college, held on St. Luke's Day, the 18th inst., the following officers were elected for the ensuing year :—President, Dr. Head ; Censors: Dr. Churchill (Vice-President), Dr. Walter G. Smith, Dr. Hawtrey Benson, Dr. MacSwiney ; Registrar, Dr. J. Magee Finny ; Treasurer, Dr. Aquilla Smith; Examiners in Midwifery, Dr. Sinclair, Dr. A. V. Macan ; additional examiners (under Supplemental Charter, 12th Dec., 1878) : Dr. W. G. Smith, in Anatomy ; Dr. Duffey, in Chemistry and in Medicine; Dr. J. W. Moore, in Materia Medica and in Hygiene ; Dr. Purser, in Physiology ; Dr. Macan, in Midwifery ; Professor of Medical Jurisprudence, Dr. Travers; Representative on the General Medical Council, Dr. A. Smith.

The following candidates were elected to the Fellowship of the College: Reuben Joshua Harvey, M.D., Dublin, 1873, L.K.Q.C.P.L., 1876 ; John Rutherford Kirkpatrick, M.B. Dublin, 1855, L.K.Q.C.P.L., 1859 ; Francis John Boxwell Quinlan, M.D., Dublin, 1862, L.K.Q.C.P.L., 1859.

The Anti-Vivisectionists and Canon Duckworth.

WE commend to the notice of the fanatics who are riding the vivisection hobby the following words uttered by Canon Duckworth in the course of his speech at the opening of Westminster Hospital for the session :—"I make bold to say a word in defence of the humanity of the whole profession, in answer to those unjust aspersions which have lately been cast upon it. To read some of the fanatical vapourings of people who are agitating for the total abolition of vivisection, one might imagine that the sole object of most youths who embrace your profession is to find indulgence for the most inhuman passions that can degrade our nature. I resent such an imputation on your behalf as a shameful libel; and I have never failed, when opportunity has been given to me, to state my firm belief that no stricter regulations than those which exist are needed to protect the lower animals from wanton cruelty at your hands. It is to me inconceivable that, from among a public which is daily enjoying the benefit of your gentleness and sympathy, daily taking advantage of your ill-remunerated and self-denying labours, there should be formed a party so unjust to you, so ignorant of your proverbial character, and so blind to facts of every-day experience."

Queen's University in Ireland.

THERE was a meeting of Convocation of the Queen's University in Dublin Castle on the 10th inst. to elect two senators in the room of the late Sir Richard Griffith and Sir Thos. Larcom. The first vacancy occurred about a year ago, and in the meantime Dr. McKeown, of Belfast, and Dr. Thornley Stoker, of Dublin, have been pushing a keen canvas for the seat. The other vacancy took place recently, and for it there was only one candidate, Mr. Wilson, of London, Barrister-at-Law.

The voting was as follows: Mr. Wilson, 247 ; Dr. McKeown, 183 ; Dr. Stoker, 82. Mr. Wilson and Dr. McKeown were declared duly elected.

Although the medical faculty is the most important, and the medical graduates number about half of the Queen's men, Dr. McKeown is at present the only representative of medicine, whilst four seats are filled by lawyers.

THE well-known Parsee philanthropist, Mr. Byramjee Jeejeebhoy, C.S.I., has given 20,000 rupees towards the establishment of a medical college at Ahmedabad, to be called after him. The same gentleman gave 40,000 rupees for a similar institution at Poonah.

The Death of Mr. Alfred H. Garrod, F.R.S.

We very much regret to observe that Dr. A. Garrod, F.R.S., has just lost his eldest son, well-known in London as one of the most distinguished of our young zoologists and comparative anatomists, at the early age of 34. Mr. Alfred H. Garrod, M.A., F.R.S., after taking a first class in natural sciences, was elected a Fellow of St. John's College, Cambridge, in 1873, and was subsequently appointed Professor of Physiology to the Royal Institution, Prosector of Anatomy to the Zoological Society, and Professor of Zoology at King's College, London. His many contributions and numerous memoirs in comparative anatomy, and on the structure and affinities of the higher vertebrate, are so well-known, that they need no special enumeration and mention.

The London Water Supply.

We learn from Col. Bolton's report, that the result of Professor Frankland's analyses of the water supplied to the metropolis during the month of September, shows that the Thames water, delivered by the several companies, Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth, was rather less polluted by organic matters than in the previous month, and all the companies filtered it efficiently. The Lea water, distributed by the East London Company, was no better than Thames water, but that sent out by the New River Company was of superior quality. The deep well water of the Kent and Colne Valley Companies, and the Tottenham Local Board, was of excellent quality for all dietetic purposes. That of the Colne Valley having been softened by Clarke's pumps, was also suitable for washing.

At the annual meeting of the Royal College of Surgeons of Edinburgh, on Wednesday last, Dr. Andrew Wood was unanimously re-elected Representative of the College in the General Medical Council for the next three years.

At the same meeting Mr. Francis Brodie Imlach, F.R.C.S. Ed., was chosen President of the Royal College of Surgeons of Edinburgh for the ensuing year; Mr. Joseph Bell, F.R.C.S. Ed., Treasurer, and Mr. David Wilson, Librarian.

We regret to announce the death of Dr. Leared, of London, which occurred on Thursday last. The deceased was a M.D. Dub., F.R.C.P. Lond., and a Member of the Royal Irish Academy. He was the author of some important medical works. Deceased was a frequent contributor to this journal, a good linguist, and a great traveller; only a few days since he returned from a holiday tour, in Portugal, where, it is reported, the seeds of typhoid were sown, which terminated in death.

According to the Registrar-General's returns the annual rates of mortality per 1,000 last week in the principal large towns in the United Kingdom, were—Bristol 14, Wolverhampton 15, Leicester 15, Portsmouth 16, Birmingham 16, Hull 17, Newcastle-on-Tyne 17, Glasgow 18, Bradford 18, Oldham 18, Brighton 18, Norwich 18, Sheffield 19, Leeds 19, Edinburgh 19, London 20, Nottingham 20, Plymouth 20, Sunderland 22, Salford 23, Manchester 24, Liverpool 25, and the highest rate 29 in Dublin.

In the principal foreign cities the rates of mortality, according to the most recent weekly returns, were—in Calcutta 30, Bombay 37, Madras 35; Paris 23; Geneva 15; Brussels 27; Amsterdam 20, Rotterdam 17; The Hague 15; Copenhagen 24; Stockholm 19; Christiania 19; St. Petersburgh 31; Berlin 31, Hamburg 27, Dresden 21, Breslau 27, Munich 35, Vienna 21, Buda-Pesth 31; Rome 31, Naples 23, Turin 27; Alexandria 35; New York 26, Brooklyn 23, Philadelphia 16, and Baltimore 18 per 1,000 of the population. Small-pox caused 9, and typhoid fever 27, deaths in Paris.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

Edinburgh University Court.—The Edinburgh University Court met on the 13th inst. Present: Principal Sir Alexander Grant, Bart., in the chair; the Lord Provost, Mr. Clark, the Rev. Dr. Lindsay Alexander, and Professor Campbell Fraser. *Inter alia*, Mr. Dittmar, Ph.D., was reappointed Examiner in Chemistry for one year, from 12th October next. Professor J. B. Balfour's resignation of the office of additional Examiner in Botany was accepted, to take effect from the end of 1879, on the understanding that a substitute should be appointed to act for him at the ensuing examination. It was ordered to be published that at the stated meeting in January next, the Court would proceed to the appointment of Examiners in Practice of Medicine, Natural History, and Botany, in succession to Dr. Duckworth and Dr. Mackintosh, whose period of office expires at the end of the present year, and Professor J. B. Balfour resigned. The appointment of Dr. D. J. Cunningham as Assistant to the Professor of Anatomy was approved.

Edinburgh Royal Maternity and Simpson Memorial Hospital.—The medical board have appointed Wm. Spence Reid, M.B., C.M., and Arthur Murray Ram, M.B., C.M., as House-Surgeons at this hospital for the quarter commencing on 1st November, in succession to George Hurst, M.B., C.M., and Thomas A. Machattie, M.B., C.M., whose term of office then expires. Dr. J. Halliday Croom has been medical officer on duty during the present quarter, and will e succeeded on 1st November by Professor Simpson.

Royal College of Surgeons of Edinburgh.—At the annual meeting of the Royal College of Surgeons of Edinburgh, held on the 15th inst., Mr. Francis Brodie Imlach was unanimously appointed president for the ensuing year, and at the same meeting Dr. Andrew Wood was unanimously re-elected representative of the College at the General Medical Council for three years from the 8th inst.

University of Aberdeen.—At a meeting of the Court of the University of Aberdeen, held on the 15th inst., the following gentlemen were appointed Examiners in Medicine for one year, viz.: Robert W. Reid, M.D., London, Robert Smith, M.A., M.B., London, T. Jeffrey Parkes, B.C., London, David Greig, M.D., Dundee, and Clement Godsman, M.D., London.

Health of Edinburgh.—During the week ending the 11th inst. the deaths in Edinburgh numbered 79, and the rate of mortality was 19 per 1,000. Only one death from fever was recorded, and that occurred in the Old Town. The mortality of the New Town was unusually low. Of the 141 births 18 were illegitimate.

The Health of Partick.—The report of Dr. Patterson, the Medical Officer of Partick, which was read at the meeting of Police Commissioners, held on the 13th inst., stated that the health of the burgh during September was good, the deaths recorded being 29 or, 12·51 per 1,000 of the population. Provost Kennedy stated that the death-rate last month was the lowest the burgh had ever reached.

Digitized by Google

HEALTH OF GLASGOW.—At a meeting of the Police Board, held on the 13th inst., Dr. Russell submitted a report, which contained the following :—During the fortnight ending 4th October there were 348 deaths registered, as compared with 376 in the fortnight preceding, representing a death-rate of 16 in place of 17½ (of 17 in place of 18¼ in our lowest estimate of the population). The death-rate in both weeks of the fortnight was the same, viz., 16. The number of deaths of persons below one year was 90, the same as in the last fortnight; and of persons aged 60 years and upwards, 52, in place of 48. The number of deaths from pulmonary diseases was 112, in place of 95, representing a death-rate of 5 in place of 4 per 1,000, and constituting 32 in place of 25 per cent. of the total deaths. The number of deaths from fever was 2 in place of 9, both from enteric fever. The number of deaths from infectious diseases of children was 17 in place of 21, viz., 13 from scarlatina, 11 from whooping-cough, and 2 from measles. The number of cases of fever registered was 72 in place of 46, viz., 58 of enteric fever, and 14 of typhus. There were also 81 cases of scarlet fever, 36 of measles, 72 of whooping-cough, and 5 of diphtheria, which were the occasion of inspection and sanitary assistance and supervision in various forms. Scarlet fever does not seem to have spread much.

KIRKINTILLOCH —MORTALITY.—There were 15 deaths during September, being equal to a death-rate for the burgh of 25·7 per 1,000. The medical officer said the high death-rate was due to the prevalent cold and wet weather; 5 deaths were those of chronic cases; 5 from diseases of the respiratory organs.

REGISTRAR-GENERAL'S RETURNS.—The weekly return of births, deaths, and marriages in the eight principal towns of Scotland for the week ending Saturday, October 11th, says: The death-rate in the eight principal towns during the week ending with Saturday the 11th October, 1879, was 17·3 per 1,000 of estimated population. This rate is 1·3 under that for the corresponding week of last year, but 0·8 above that for the previous week of the present year. The lowest mortality was recorded in Perth, viz., 7·8; and the highest in Paisley, viz., 21·3. The mortality from the seven most familiar zymotic diseases was at the rate of 3·2 per 1,000, being 0.7 above that for the previous week. The increase was chiefly due to diarrhœa. A death from diphtheria was the only one which resulted from these diseases in Greenock.

PROSECUTION UNDER THE FOOD AND DRUGS ACT.—Before Sheriff Spens, of Glasgow, on the 16th inst., Alexander Beaton Chalmers, druggist, 229 Stirling Road, pleaded guilty to a charge at the instance of the sanitary department of having sold powders prescribed for a patient of Dr. Neil Carmichæl's, in which the ingredients were defective in quantity to the extent of seven-eighths in each powder. A penalty of £5 was imposed.

SCOTTISH AMICABLE LIFE ASSURANCE SOCIETY.—Dr. Leishman has, it is understood, been appointed medical adviser to this society, instead of the late Dr. J. G. Fleming. The contest was a keen one, the patricians of the profession being in *en masse*. "It's worth the risk to life and limb and neck, boys, £300 per annum!"

TRIPLETS.—A case of triplets occurred in the practice of Dr. A. I. Kelly, of Glasgow, recently. The infant children, three boys, are now aged six weeks, and all doing well.

FIRE IN A LUNATIC ASYLUM.—A fire broke out on Thursday night in the West Tower of Woodike Lunatic Asylum, Lenzie, near Glasgow. It was caused by the scullery chimney taking fire and igniting a wooden cupola surmounting the tower. The fire brigade of the institution and a detachment of the Glasgow brigade, which soon reached the scene, succeeded in confining the flames to the tower, which has been completely gutted. There were 500 inmates in the asylum. No one was injured. The damage is estimated at about £6,000.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of the 15th inst., your Northern Correspondent uses an expression (too infamous to repeat) concerning what he is pleased to designate the "Romish Church." So gratuitous an insult to every Roman Catholic reader of your paper, it would be hard to equal, and impossible to surpass. I am sorry to have to complain that remarks of a similar nature, though not so atrocious, have too frequently defiled the pages of your journal.

As your Northern Correspondent is so invinci bly ignorant as not to know, or so rude as to not to care, when he insults the religious convictions of your Roman Catholic readers, I must appeal to you, sir, to insert this letter as a protest against such vulgar ribaldry, and now that attention has been drawn to the matter, I hope to be able to avail myself of the pleasure of reading the *Medical Press and Circular* without hearing my religion spoken of in this semi-blasphemous manner.

Yours, &c.,

A ROMAN CATHOLIC DOCTOR.

[We insert the letter as requested lest it might be supposed by our correspondent that we are afraid of rebuke. But we think him rather gushing and unnecessarily indignant. We have distinctly stated that we do not identify the journal with the opinions of its correspondents, and we are, therefore, not directly answerable for our Northern correspondent's peccadillo. We do not approve of the introduction of religious controversies into the pages of a medical journal, and should, therefore, have struck out the observation complained of, but that it, unfortunately escaped our attention. Moreover, it is not true, as stated, that we have ever permitted publication of "remarks of a similar nature," and we shall feel particularly obliged if our correspondents at large will understand that their business is to chronicle and criticise medico-chirurgical, scientific, and medico-political matters, and to reserve their views upon religious subject for debate elsewhere than in our pages.—ED. M. P. & C.]

Correspondence.

THE CLAMOUR ABOUT VIVISECTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As the cycles revolve it would seem the same ideas return. The recent scare about vivisection is but an epidemic similar to that which prevailed in 1820. There was then a vulgar outcry against direct experiment upon living animals, which drew forth an indignant protest from Dr. Barry, to whom we are indebted for so much light on the subject of the circulation and poisoned wounds.

Hypocritical cant takes the place of true philanthropy, and the vociferations against the pretended evils of vivisection are but the utterances of hypersensitive fanatics. Your able advocacy of the question entitles you to the best thanks of the practitioners of Great Britain. The universal consensus of the profession is in favour of experimentation, conducted under certain conditions, by means of which the greatest amount of good, not only to man, but to all other animals, is attained and the least amount of suffering inflicted upon the victim. It is useless to recapitulate all the arguments in favour of vivisection, or to adduce the opinions of anatomists of bygone ages on its importance for the progress of medical science. We know it has been practised by men of the deepest religious feelings, by Harvey, Haller, Hunter, &c., and that the results have been of incalculable service, not only in human but in veterinary medicine, and it is almost lamentable to think that we have still to insist upon its necessity, or that it is necessary to distribute the address of Dr. Pye-Smith as a corrective, as suggested by Mr. Jabez Hogg in the *Press and Circular* of August, 1879, to counteract the craze of the anti-vivisectionists. In Dr. Barry's time a few hypersensitive surgeons joined in the cry, and Dr. Barry had to contend not only with public, but professional, ignorance, and he well says of both classes of opponents: "They who inveigh most loudly against experiments upon living animals, and who affect an excess of sensibility, have never made any experiments themselves. They are contented with the exposition of what they in their wisdom suppose Nature ought to do, instead of investigating what she actually does."

Others talk of needless cruelty. If any useful knowledge is to be obtained by an experiment, none of the means necessary to arrive at this knowledge can be needless, and none else can be adopted without defeating the purpose aimed at; therefore, in useful experiments there never is needless cruelty, or, in other words, unnecessary pain inflicted.

Digitized by Google

When medical men are praised at public meetings, and their letters read with applause, in which they express their determination neither to open the living body of animal nature themselves nor permit it to be opened by the youths committed to their charge, our best feelings are allowed to take a very wrong direction. There are those, however, who have had the candour and the honesty to assert in the face of this vulgar clamour, that we have as good a right to make animal life subservient to the increase of our useful knowledge as of our bodily strength and amusement. This is plain common sense, and must in the end prevail.

Yours, &c., COMMON SENSE.

CALOMEL IN TYPHOID FEVER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with much interest the communication in your pages concerning the origin of typhoid fever, and the use of calomel in treating that disease. I, for one, am quite willing to receive Mr. E. Marlett Boddy's explanations as correct and his treatment as proper, if I find them borne out by further experience; but I am anxious to know how he reconciles the following facts with his statements—viz., that at the commencement of a case of typhoid fever, we rarely, if ever, are able to discover the presence of fæcal accumulation in the intestines; that after the onset of diarrhœa we rarely find scybellæ in the stools, and when scybellæ do appear they are present in such small quantity that they would not lead one to suppose constipation had existed for any length of time. Also, that many well authenticated cases on record, which seem to prove conclusively the infectious nature of the malady; an opinion entertained by no less an authority than the late Dr. Stokes. Lastly, if typhoid fever is produced by constipation, how are we to account for the fact that it frequently occurs as an epidemic.

Yours truly,

Oct. 17th, 1879. G. HARRISON YOUNGE, L.K.Q.C.P.I.

Literature.

TRANSACTIONS OF THE ROYAL MICROSCOPICAL SOCIETY. (a)

THE Transactions of the Royal Microscopical Society, under the able editorship of Mr. Frank Crisp, have become a thorough record of current research, relating to microscopical science. The August and October parts contain papers and matters of much interest and value. Mr. H. J. Carter, F.R.S., F.R.C.S., contributes, first, a paper "On a new Species of Excavating Sponge"; second, a "new Species of Rhaphidotheca;" and third, "a new Genius of Foraminifera." Professor Balbani's observations on a new parasite he lately discovered on Notemmata Werneckii, clear up a matter which has puzzled many microscopists, namely, the horny excessories or swellings that often occur on the Vancheria. These swellings, it now appears, are the work of a parasite, a minute cyclops-lapula, which bores its way into the cellular tissue of the plant, thus inducing a disease almost identical with that recognised under the term gall. This form of parasitism is but little known, and the learned Professor has conferred a service upon microscopists by tracing out the several phases of its existence, and accurately delineating them in a series of well-executed drawings, and which have been admirably transferred to the "Transactions." We cannot, however, say so much for all the drawings, that of the kidney and iris, page 612, are both far behind the ordinary run of those met with in our manuals. Dr. Fripp's paper "On the Theory of Illuminating Apparatus," is far too diffuse in its general characters, and he appears to have unnecessarily occupied a large amount of space to the depreciation of the labours of other writers. When a writer on a given subject thinks it necessary to comment upon so essentially a modern scientific instrument, as the compound achromatic microscope, and devotes page after page to matters, written when it was in its veriest infancy; then all such references, whether they exhibit the truth or fallacy of the views enunciated, must be pronounced irrelevant to the general issue. Dr. Fripp would have us believe that it was the duty of the earlier writers of manuals for the microscope to have first furnished the student with an elaborate treatise on optical science, as a necessary preliminary to the use of the microscope. It does appear, however, by his own showing, that an attempt of the kind might, for many good reasons, have been a signal failure, or at all events, have frustrated his object, for what do we find? Why, that Dr. Fripp devotes no less than eight diagrams! one of which, by the way, he and his draughtsman have contrived to render unintelligible, and twenty-six octave pages to the explanation of certain views, he entertains, in the identity or non-identity of the action of the plane and concave mirrors in reflecting parallel or converging rays, and in quoting from Wollaston and Brewster data, for the construction of illuminators, which he (Dr. Fripp) thinks worthy of support or condemnation. We can scarcely imagine that any other writer "On the Theory of Illuminating Apparatus," would not have looked upon this parade of obsolete discussions and appliances as an utter waste of time. Nor does Dr. Fripp mend matters by references to the views of Helmholtz and Abbe, which he gives in so abstract a form as to almost defy comprehension. We cannot then close our eyes to the fact that he has travelled out of his way to depreciate certain well-known popular hand-books of the microscopes from one or other of which he, in all probability, obtained his earliest knowledge of the use of the instrument, because forsooth, they do not enter into the theory and practice of the most modern appliances, and which it is quite certain are not perfectly well understood by half-a-dozen men in England. Indeed, we notice with some surprise tha even the latest German writers on the microscope. Nageli and Schmender, 1877, quoted by Dr. Fripp, fall far short of the mark in this matter, we, therefore, wait the termination of the papers before we can attempt to assign to Dr. Fripp the credit he evidently thinks his due for the labour bestowed in collating and presenting us with "scientific" views of the subject, premising that as he has found a field so congenial and open to him, in which he claims to be the first in this country to treat scientifically, we shall expect matter of a superior quality to that which appears in Part I., otherwise we shall feel constrained to fall back upon the old-fashioned rule of thumb, or, "the ordinary school boy crib from some elementary treatise on dioptrics."

We have scarcely reserved space enough to notice the papers of Dr. Wm. Ord, "On the Cause of Brownian Movements," of Dr. Woodward, "On the Study of Amphipleura," and of the laboriously compiled "Record of Current Research," classified and arranged for the use of the student in zoology, botany, and microscopy.

(a) "Royal Microscopical Society's Transactions and Proceedings." 1879.

Novelties.

CHEILO-ANGIOSCOPY.

DR. HÜTER, of Griefswald, has been the first to extend the actual observation of capillary circulation to the human subject. It is a matter of some surprise that the obvious ease with which, in the lower animals, the course of the blood through plexuses of small vessels can be seen, has not long before this led to the application of a similar mode of determining the conditions under which the circulation is proceeding in the diseased. Dr. Hüter's apparatus for effecting this is so simple and so readily available, that we may look to see its use introduced largely in the future as

Digitized by Google

an aid to diagnosis- It consists of a small fixed platform which is brought conveniently near to the head of the patient, a spring clip serving to hold the head in a fixed position. The under lip is then drawn out and forward, and secured on the little platform by means of a padded spring holdfast. A brilliant light being thrown on the upturned mucous surface, the delicate capillary network is evident even to the naked eye. However, a microscope of low power can be easily adjusted for more accurate examination, and by its aid the most valuable information is obtained concerning the condition of the blood, the relative proportion of red and white corpuscles, rapidity of flow, &c., &c. By slight pressure on the lip it is possible to produce all the phenomena of stasis, and the epithelial cells of the mucous lining of the mouth can be perfectly seen. We can readily agree with the inventor of the cheilo-angoscopic apparatus that its extensive employment will immensely assist the medical practitioner in attaining a speedy and accurate acquaintance with the most important data to guide him in forming his estimate of a patient's state.

THE "PERFECTED" COD LIVER OIL.

VARIOUS attempts have been made from time to time to render cod-liver oil less nauseous to patients; and experiments have been devised by importers to disguise its objectionable flavour with the aid of syrups. But these have not met with the success they deserved, which is probably owing to the notion—often wrongly entertained—that the disguise was nothing more than adulteration or the masking of an inferior article. Messrs. Allen & Hanbury, one of the oldest established drug-houses in London, having fisheries and manufactories in Norway, have tried to meet these difficulties and objections by introducing the first quality of oil, in the highest degree of purification, which they term the "Perfected" Cod-Liver Oil. We are, of course, unaware of the process of refinement by which the removal of the fishy taste and odour have been removed, but we understand that it is the result of years of study and experiment. This much we can say; having personally tested it, and having moreover given it to one or two delicate patients, we think the most fastidious will not object to take it on the score of taste, and no nauseous eructations follow after it is swallowed. We wish Messrs. Allen and Hanbury success with their venture, although we fear the price is prohibitory for hospital use.

LIQUOR OPII. DIALYSATUS.

AVAILING themselves of the well-known law of endosmosis the well-known firm, Corbyn, Stacey and Company, have been the first to introduce a preparation of opium which we consider likely to be of use, and we gladly welcome this addition to our list of remedies. The solution contains all the crystaline active principles of opium in the same relative proportions as the crude drug, being quite free from extractive, resinous, waxy, and caoutchouc substances, and retaining only a minimum proportion of colouring matter. The continued use of it does not produce constipation, headache, or stomach disturbances.

The dose is the same as the ordinary tincture of opium.

SYR. HYPOPHOS. COMP. FELLOWS.

THIS is a genuine compound syrup of the hypophosphites, in fact it is our ancient friend, Easton's syrup, with the addition of manganese, lime, potassa, and hypophosphoric acid. The combination is said to be due to the experiments of Mr. Fellows, a chemist of St. John's, New Brunswick, "who treated and cured himself by its use of pulmonary tuberculosis in 1865." Not having stethoscoped Mr. Fellows, and not having had the opportunity of testing its curative powers in the disease from which he is said to have suffered, we can only vouch for the composition of the preparation, that it contains in a very agreeable form the ingredients specified. The importers are Messrs. Burroughs and Co., 8 Snow Hill, London.

King and Queen's College of Physicians, Ireland.—At the October examinations the following gentlemen obtained the licence in Medicine and Midwifery of the College:—

MEDICINE.—Dean Bennett, John Noble Bredin, Charles Davidson, John Farrell Esmon, Hugh Parry Jones, George Robert Lawless, Joseph M'Donnell, Michael de Courcy O'Grady, George Thomas Albert Staff.

MIDWIFERY.—Charles Davidson, John Farrell Esmon, Joas Henrique Fialho, Hugh Parry Jones, Joseph M'Donnell, Thos. Beattie Moffitt, Michael De Courcy O'Grady, George Staff.

Dublin Sanitary Commission.—Mr. W. Jerrold Dixon, eldest son of Mr. Hepworth Dixon, Secretary to the Royal Sanitary Commission, was found dead in his bed on Monday morning, in Belgrave Square, Dublin. He had only concluded his labours on the Committee, which has been sitting during the last fortnight, on Saturday last.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

MR. F. WILSON.—Under the title of "Foreign Degrees, and How to Obtain them," in our issue of Oct. 1st, you will find all you desire to know on this question. We do not advise the taking of these degrees; those obtainable in this country are of more value in every way. Foreign diplomas of recognised universities are only useful in the way indicated in our article.

MR. DOUGLAS HEMMING, Bournemouth.—Received with thanks; will appear in an early number.

THE EDITOR, *New York Med. Gaz.*—In reply to your communication, we have directed our journal to be forwarded regularly in exchange.

CHROMIDROSIS.—See Tilbury Fox on "Cutaneous Diseases."

OLEUM ZINCI.—We have no formula for this preparation.

EMIGRATION.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I have a little book in hand, "Hard Times, and How to Meet them." I shall have a chapter on emigration. I shall be greatly obliged if any of your readers can add reliable information to what I have already got relative to the suitability of different countries for emigrants.

I am particularly anxious for information that will meet the case of small tradesmen, shopkeepers, clerks, and others who have no handicraft and no capital.

I have also a chapter on diet, and shall be glad of receipts for cheap dishes.

Yours, &c.,

Parsonstown, Oct. 14, 1879. ALEX. WALLACE.

HARVEIAN SOCIETY OF LONDON.—On Thursday, Nov. 6, at 8.30 p.m., "Intra-Cranial Syphilis," by Dr. Hughlings Jackson.—"The Action of Salicine and Salicylic Acid in Rheumatism," by Dr. W. Squire.

THE PORO-PLASTIC JACKET.—Mr. Cocking is anxious to correct a slight inaccuracy which occurred in Mr. Ormsby's communication last week: Mr. Cocking is made to say that surgeons can easily apply the jacket "without the aid of surgical instruments;" it should read, "surgical instrument *makers*," no small advantage in remote districts and to country patients.

PAUPERISM AND DRINK IN WORKHOUSES.—We have received from Mr. Dolan, F.R.C.P., of Halifax, a paper on this much debated question, with valuable tables and statistics, which we hope to place before our readers in an early number.

SEWER GAS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Your annotation on this subject last week induces me to write to suggest that if over "each opening from which sewer-gas now rises" a post was erected like a lamp-post, the gas would be carried above the heads of passers-by, and so get mixed with the open air as to render the effluvia innoxious. If you think the suggestion worth anything, please publish this short note in your useful journal.

Yours faithfully,

13 Delahay Street, Westminster. THOS. HAMILTON.

MR. MORTIBOY.—The Students' Number contains all the information you require. You will be able to see it at almost any of the medical colleges and principal hospital reading-rooms. It is out of print at our office.

CLINICAL SOCIETY OF LONDON.—On Friday, Oct. 24, at 8½ p.m., Dr. Southey, "On Two Cases of Acute Rheumatism."—Mr. Lawson, "On Cancer of the Breast following upon Eczema of the Nipple of long standing."—Dr. Wilks (of Ashford), "On a Case in which a Man was Struck by Lightning."

VACANCIES.

Ardee Union, Castlebellingham Dispensary.—Medical Officer. Salary, £100, with fees, and £15 as Sanitary Officer. Election, Oct. 24.

Bromyard Union, Herefordshire.—Medical Officer for No. 2 District. Salary, £150. Also for Workhouse. Salary, £30. Applications to the Clerk of the Guardians before Oct. 30.

Castlerea Union, Castlerea Dispensary.—Medical Officer. Salary, £100, with fees, and £25 as Medical Officer of Health. Election, Nov. 1,

Digitized by Google

Chipping-Norton Union.—Medical Officer for District No. 2. Salary, £65. Also for Workhouse. Salary, £40. Applications to the Clerk before Nov. 4.

Macclesfield Infirmary.—Junior House Surgeon. Salary, £70, with board. Applications to the Chairman of House Committee on or before Oct. 27.

Northampton General Infirmary.—Resident Medical Officer. Salary, £100, with board. Applications to the Secretary before Nov. 3.

Royal Free Hospital, London.—Assistant Surgeon on the Staff. Applications to the Secretary on or before October 16. (See Advt.)

West Sussex Infirmary.—House Surgeon. Salary, £80, with board, and £20 extra for duties as Secretary. Applications to the Secretary at the Infirmary, Chichester, before Oct. 25.

APPOINTMENTS.

BALL, C. B., M.D., M.Ch. Univ. Dub., Demonstrator of Anatomy to the School of Physic, Trinity College, Dublin.

CALLAN, M., L.K.Q.C.P.I. & L.M., L.R.C.S.I., Medical Officer to the Workhouse, Ardee Union, co. Louth, and Consulting Medical Officer of Health.

COYNE, F. K., L.R.C.S.I., L.K.Q.C.P.I., Medical Officer to the Ballyroan Dispensary, Abbeyleix Union.

D'ALTON, P. R., L.R.C.S.I., L.K.Q.C.P.I., Medical Officer, &c., for the Boffin Division, Clifden Dispensary, Clifden Union, and Medical Attendant to the Royal Irish Constabulary.

FAIRCLOUGH, J. J. K., M.D., L.K.Q.C.P.I., M.R.C.S.E., a Surgeon to the Chorlton-on-Medlock Dispensary.

FENWICK, S., M.D., F.R.C.P.L., a Physician to the In-patients of the London Hospital.

FIRTH, C., M.B., F.R.C.S.E., a Medical Officer to the Norwich Dispensary.

KING, W. L., L.R.C.P.Ed., M.R.C.S.E., Medical Officer for the No. 4 District of the Downham Union.

MACALISTER, A., A.B., M.B. Univ. Dub., L.R.C.S.I., Professor of Anatomy to the School of Physic, University of Dublin.

MAYER, D., M.D., C.M., Medical Officer for the Parish of Dalrymple, Ayrshire.

NUGENT, G. P., M.B., B.Ch. Univ. Dub., Demonstrator of Anatomy to the School of Physic, Trinity College, Dublin.

SCATLIFF, J. M. E., M.D., Honorary Physician to St. Mary's Hospital, Brighton.

SIMON, R. M., M.B., B.A., M.R.C.P.L., Assistant Physician to the General Hospital, Birmingham.

WILSON, T., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer for the Yoxall District of the Lichfield Union.

ARMY MEDICAL DEPARTMENT.—Surgeon-Major A. Johnstone, M.D., retires on temporary half-pay; Surgeon-General T. Crawford, Principal Medical Officer in Ireland, embarks for India early next month to assume duty as Chief of the Medical Department of the Indian Army: Deputy Surgeon-General E. Gilborne has returned to Dublin from leave of absence and resumed duty as Principal Medical Officer of the Dublin District.

NAVY MEDICAL SERVICE.—Staff-Surgeon Geo. Hill to H.M.S. *Comus*; Staff-Surgeon George H. Madeley, to H.M.S. *Albatross*; Surgeon Jas. B. Clibborn to H.M.S. *Comus*.

Births.

FALKNER.—On Oct. 11, at 10 Breffni Terrace, Kingstown, the wife of R. Falkner, L.R.C.S.I., of a daughter.

FRAZER.—On Oct. 15, at Yorevale, Bournemouth, the wife of William Fraser, M.D., of a daughter.

LEARY.—On Oct. 13, at Castlederg, co. Tyrone, the wife of T. Leary, L.R.C.S.I., of a son.

LITTLE.—On October 12, at 14 Stephen's Green N., Dublin, the wife of James Little, M.D., of a son.

WHITE.—On Oct. 10, at Kingston-on-Thames, the wife of George Farr White, F.R.C.S., of a son.

Marriages.

BLOOD—DRURY.—On Oct. 9, at Whitechurch, Robert Blood, M.D., A.M.D., to Catherine Sarah, youngest daughter of Wm. B. Drury, Esq., Boden Park, Rathfarnam, co. Dublin.

LAWLOR—MAGEE.—On Oct 15, at Terenure, co. Dublin, Joseph S. Lawlor, M.D., Delaforde House, Templeogue, to Agnes, youngest daughter of James Magee, Terenure Road.

RICHARDSON—FLEMING.—On Oct. 15, at Christ Church, Edinburgh, Ralph Richardson, Writer to the Signet, to Mellville, eldest daughter of Andrew Fleming, M.D., Bengal Army.

WIDDUP—PEEBLES.—On Sept. 30, at Glasgow, John Charles Ponsonby Widdup, M.D., L.R.C.S.I., to Zoila Elena, third daughter of Robt. H. Peebles, Esq., of Chanaral, Chili, South America.

Deaths.

BLACK.—On Oct. 12, at Queen Anne Street, Patrick Black, M.D. aged 66.

DUNNAGE.—On Oct. 15, at Ailbury House, Surbiton, Arthur R. Dunnage, M.R.C.S., aged 32.

FLEMING.—On Oct. 11, at Hope Bank, Dunoon, J. Fleming, L.F.P.S.G., late of Glasgow, aged 78.

INNES.—On Oct. 5, at Rhyl, James Innes, M.R.C.S.E., formerly of the Hon. East India Company's Madras Medical Service.

JAGOE.—At Bandon, co. Cork, Benjamin Jagoe, M.R.C.S.I.

SHEDLOCK.—On Oct. 9, at Madeira, Rose Anna, fourth daughter of the late Rev. John Shedlock, M.A., aged 29. Friends will kindly accept this intimation.

FITZGERALD.—On Oct. 15, at Tiverton-on-Avon, Bath, Dudley L. Fitzgerald, M.D., T.C.D., aged 30.

LEARED.—On Oct. 11, at 126 Old Burlington Street, London, Arthur Leared, M.D., F.R.C.P., M.R.I.A.

PEARSE.—On Oct. 14, Elizabeth, wife of Charles T. Pearse, M.D., late of Croydon, aged 74.

SALTER.—On Oct. 15, at Bovingdon, Herts, Eliza, widow of Thos. Salter, J.P., F.R.C.S., late of Poole, Dorset, aged 90.

Intermediate School of Art, IRELAND.

ANATOMICAL & PATHOLOGICAL SECTION.

THE Class for Anatomical and Pathological Modelling and Construction of Wax Coloured Preparations, Drawing, and Colouring in Water, will open on 1st October, under the Direction of JOHN WOODHOUSE, A.R.H.A., at

11 HARRINGTON STREET,

Medical Men and Students in Medicine and Surgery are specially invited as this Class is intended for them chiefly.

Syllabus, Fees, and Further Particulars may be had on application from—

WILLIAM H. ARCHER,
(Surgical Artist) Secretary,

IRISH POOR-LAW INTELLIGENCE.

THE IRISH PRISON SURGEONS.

On Wednesday evening, at five o'clock, a deputation from the surgeons of prisons in Ireland waited on the Chief Secretary, at the Castle, to express the views of that body with respect to the proposed scale of salaries under the new regulations. The deputation consisted of the following :—Dr. Brunker (Dublin), Dr, Thompson (Omagh), Dr. Jacob (Maryborough), Dr. Kincaid (Galway), Dr. Middleton (Mullingar), Dr. Mayne (Longford), and Dr. Johnston (Kilkenny).

Dr. Brunker, addressing the Chief Secretary, said—When I had the honour of waiting on you, sir, in company with Dr. Maconchy, in London, in July last, after hearing the statement then made you were kind enough to say you would confer with the Treasury on the subject of the prison officers' salaries. As we were informed that the Chancellor of the Exchequer and the Secretary of the Treasury would be in Ireland early this month to make inquiry into several important matters, and it was believed these salaries would then be finally settled, we were anxious to have an interview with you, and are much obliged for your kindness in granting it. At a meeting of the prison surgeons of Ireland, held on the 7th of October, the following resolutions were unanimously agreed to :—1. "That we respectfully ask the Government to reconsider the proposed salaries of the medical officers of prisons, as considering the very great increase of duties to be performed at present, in many cases three or four-fold, we are of opinion that the salaries offered us are quite insufficient as remuneration for the greatly increased responsibilities and many duties we are called on to perform. 2. That in the event of our reasonable request being conceded, then that such surgeons as are unwilling to undertake the mechanical duties of compounding should be allowed either to employ a compounder, who should have access to the jail surgery when required, or be supplied with a suitable hospital warder." Such an arrangement would be most likely to smooth the compounding difficulties, and induce most if not all the prison surgeons to meet the wishes of the General Prisons Board, and cheerfully assume the responsibility of superintending the compounding. The following opinion of the College of Physicians, expressed in a memorial presented to the Lord-Lieutenant, is most important :—"That your memorialists are of opinion that it is highly desirable that in such public institutions as the prisons there should be a second officer through whose hands the prescriptions should pass, that in the case of an inquiry at an inquest, &c., the public should be satisfied that all legitimate means had been used. Your memorialists pray that your Grace will take the foregoing matters into your favourable consideration, and take such measures that each prison shall contain among its officials a properly qualified compounder." The attention of the Government is respectfully called to the salaries of the surgeons of the English prisons, many of which do not contain a greater number of prisoners than do some of the Irish prisons, and in which the duties are much more trying, and appear to occupy a greater portion of time, as will appear from some of the Irish prison surgeons which will be laid before you. The following is an extract from the resolution of the College of Surgeons :—"That in the opinion of this Council the proposition of the General Prisons Board to the effect that surgeons of prisons shall be required to compound medicines, without affording them any option, unless at a loss of salary, is highly objectionable." There are various provisions and rules which the medical officers feel as pressing hardly upon them, and which can be advantageously altered, but they will endeavour to meet the wishes of the General Prisons Board as they are now announced, relying on the fair consideration of individual cases and remuneration.

Dr. Jacob asked leave to say a few words in explanation of the statement which had just been made, and to renew their assurance of their readiness to carry out the rules of the General Prisons Board as they now exist. They should do so cheerfully and to the best of their ability. They felt that some of them—most of them—might be greatly softened in such a way as to press less severely upon them. Some of them were such as to lead to a great deal of hardship and unnecessary vexation. Though he was aware of only one instance where that means of annoyance had been brought to bear on the prison surgeons, yet the rules were such that they might be made the means of giving great annoyance. However, their object in coming there that day was not so much to ask a reconsideration of the rules. That would hardly become them. Their object in addressing the Chief Secretary was to ask him again to have the scale of salaries that was proposed to be offered to them reconsidered. Some of them felt that they were really insufficient; and no doubt he (the Chief Secretary) would feel they were insufficient if he read that portion of the prison rules which applied to the medical officers. His own (Dr. Jacob's) was about the medium place on the scale. In his case the salary offered him was 3s. 3d. a day. In addition to all that had been stated there were certain dangers surrounding their position. He had charge of some 55 or 60 convicts. He had daily intercourse with them. He was the medium of communication between them and the Government, under whose control they were. They were placed in the position of detectives, if he might say so, between these men and the board. If a man said he was sick they were to say whether he was an impostor or not. If the doctor said the man was not ill he immediately took a dislike to the doctor. He himself had been threatened several times by prisoners, and many others had been threatened.

The Chief Secretary—How threatened?

Dr. Jacob—Threatened with assault; several doctors had been severely wounded.

The Chief Secretary—In the prison?

Dr. Jacob—In the prison, and threats had been made

Digitized by Google

after leaving the prison. He could exhibit a poniard that was prepared for his father on one occasion. This should not be forgotten in considering the salaries. There were many other duties which they were called upon to perform, and which did not appear in the rules. The prison surgeon was the medium between the Government and the prisoner. He was not to be the instrument of a prisoner, or to pass over a sick person from carelessness or inattention. If he might venture to say so, if he (the Chief Secretary) were ill and sent for a medical man, the latter assumed that all he stated to him was true or believed it to be so; and when they came to deal with a prisoner they had to divide their attention between reality and his statements. He had to deal with a troublesome set of men, and so far as numbers were concerned he occupied a middle-class position.

The Chief Secretary—Better for me to say at once that the Government have decided to appoint a departmental committee to report upon this question, with the view of ascertaining how the matter really stands. Any statements you may have in writing will be of value if you can send them in to that committee. That is the course we propose to adopt.

Dr. Thompson drew attention to the increased duties put upon them since the Government took over the prisons. The duties were increased fourfold. In the Omagh prison he was obliged to visit prisoners within twenty-four hours after admission, to inspect them before their discharge, to visit every prisoner in the hospital every day, to visit every prisoner in the dark cell every day, visit every prisoner previous to his being placed on punishment, and to inspect the diet. For these increased duties he received no additional salary. The salary of the Roman Catholic chaplain had been £40, that of the Protestant chaplain £40, and that of the Presbyterian chaplain £40. Part of their duties consisted not only in attending to the spiritual wants of the prisoners, but also inspecting the diets. This latter duty had been taken off them, but the salary of the Roman Catholic chaplain had been doubled, and that of the Protestant chaplain increased by one-third. He, of course, did not object to the salaries of the chaplains being increased. Referring to the duty of compounding, he said in Ireland most of the doctors had not been accustomed to compound medicines, as was the case in England.

Dr. Jacob pointed out that there were several doctors that had never compounded during their life, and that could not see their way to undertake it now. He had neither the leisure nor the inclination to undertake it, and he really could not do it if he were willing to do so.

The Chief Secretary said the only object of the committee to which he had referred would be to consider each individual case on its merits, and not so much to lay down general propositions.

Dr. Jacob.—May I ask if that committee would deal with the question of compounding or confine its study to what would be a proper salary?

The Chief Secretary.—The object would be to consider the whole question of the remuneration of prison officers. I am glad to find that matters have advanced a great deal since I last had the pleasure of meeting you. Gentlemen then spoke of compounding as derogatory to the profession, and I pointed out that some of the most distinguished gentlemen in the profession in England had no objection to compounding. It seems to me to be more a question of compensation than anything else.

Dr. Thompson. Certainly, I would have no objection to compounding.

Dr. Jacob said no amount of salary could compensate him for the amount of time compounding would occupy, and he supposed the time of many prison surgeons was as valuable as his.

Dr. Thompson remarked that, by the rules of the College of Surgeons, some doctors were prohibited from compounding.

The Chief Secretary said he thought that would be a good argument to bring before the council as to the advisability of having compounding omitted. He thought, however, that the probability was that the duties of compounding would have to be discharged.

Dr. Kincaid said that some men, who had not been educated in the matter of compounding, could not undertake the duties now.

The Chief Secretary thought the course for such men as that to adopt would be to resign.

Dr. Jacob said he would not be prepared to resign. In four years more, if he should become incapacitated, he would be entitled to a substantial pension, which would be forfeited if he resigned.

The Chief Secretary hoped Dr. Jacob would be spared for many years to come, and that his services would not be discontinued. If all these matters were put into shape, he would take care that they were submitted to the committee.

Dr. Thompson asked if they could count upon being paid for the last two years.

The Chief Secretary said he would rather not go into that. But the committee should go into it, and consider the particular merits of each case.

Dr. Jacob asked if the decision of the committee would be final in the matter?

The Chief Secretary explained that the committee was a departmental one, appointed to go into these matters. That committee would not do anything more than consider the matters and report to the Government.

The deputation then withdrew.

REDUCTION OF SALARIES.

To the Poor-law Medical Officers of Ireland.

Gentlemen, — Already proposals for reducing our miserable salaries have been adopted by some Boards of Guardians, and would, notwithstanding the gross injustice to us, have been carried into effect, but for the timely interposition of the Local Government Board.

Indeed, in dealing with us, illiberality seems to be the dominant principle of most guardians; but never did the niggard, cheeseparing disposition manifest itself at a more inopportune juncture. Monetarily affected by the loss of all collateral sources of income, and menaced by a recurrence of the untold hardships and privations that fell to our lot during the disastrous famine years, we perhaps needed this last indignity to stir up amongst us a spirit of resistance and self-reliance, through which alone we can expect redress. Though not unmindful of the action of the Local Government Board in this matter, I must say that we ourselves are to a great degree responsible for this and antecedent ill-treatment, such as would never have been presumed upon had not the public accurately estimated the feeble resistance to be anticipated from isolated members of a disorganised profession.

Emancipating ourselves from the baneful influences of anarchy and disunion, and adopting the motto that unity is strength, let us even now join issue, and see if, by unanimity and determination, we shall not yet achieve more suitable recognition for our services.

Towards this end, I would in the first instance suggest, that in future no medical man shall canvass for, or accept of, any dispensary appointment, unless the salary be at least £200 per annum, or, if a workhouse, £140, the minimum remuneration for temporary duties to be also fixed at £4 per week. Any deviation from this rule to cause the delinquent to be cold-shouldered and black-balled by the entire profession. If this were so, guardians would be deprived of at least one argument frequently used against us, namely, that if we resigned our appointments others would be had to accept of them at any remuneration they thought proper to offer.

Digitized by Google

Next I submit that, as in the case of civil servants, we are fully entitled to a resonable period of leave of absence at the public expense. Such an arrangemement would increase the efficiency of the service, and thereby prove beneficial to the public interest. This could be carried out readily, and with little expense, by a staff officer being appointed for each province who could successfully discharge the temporary duties, his salary, of say £200 a year, to be apportioned equally on the several dispensary districts.

Further, it would be but an act of justice that those who have served twenty years, or attained the age of sixty, who have been physically incapacitated, should, as a matter of right, receive superannuation allowance, in amount not less than two-thirds of their official emoluments. Outsiders, though apt to detract, never reflect on all that is required of us. We may be called to the performance of most arduous duties at any time, in any weather, to any place, however distant or difficult of approach.

This goes on uninterruptedly, year after year, without even the slight remission the Sabbath brings to others. At home we are momentarily interrupted by messengers from every fever nest and pestiferous den in the several districts, who come at all hours to report progress of afflicted relations; if absent, they often hang about for hours, to the detriment of our families, amongst whom they frequently import contagion. The selfish ingratitude that could, under the circumstances, suggest a diminution of our scanty remuneration, should be amply significant; and inasmuch as we are driven to a strike, let it be rather for the amendments I have suggested than against the proposed reduction, which I hold to be illegal, and beyond the power of guardians to enforce. Incessant agitation and unremitting energy on our part, together with the reliable assistance of the Irish Medical Association, to whom we are already deeply indebted, must ultimately lead to the attainment of those ends which I regard but as an instalment of what is due to us. On the principle that it is base for a man to suffer when he ought to act, I raise my voice in this matter, and only regret that some of my more gifted confreres have not felt called upon to do so. If you sustain me, and bear in mind my parting advice (which is that you be men to-day, or be for ever slaves), the time is not far distant when our demands will be acceded to.

Yours faithfully,

Oct. 16, 1879. SCARLET RUNNER.

FEES FOR TEMPORARY POOR-LAW SERVICE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—One evening last August a very urgent message was sent to me by a member of the dispensary committee of this district, asking me to attend a woman in her confinement as the medical officer was absent, and had been so all day. I attended at once and delivered the woman, who was in a most critical state.

In due time I applied to the guardians for my fee, the case was referred by them to the local committee, when by a majority of five votes to four my claim was disallowed. I then applied to the Local Government Board with the same result.

Considering that I have been very shabbily treated in this case by all concerned, I would be obliged if you would inform me whether I could recover my fee by taking action against the Board of Guardians. You may say that the member of committee who sent for me is responsible, but I do not wish to punish him for two reasons: 1st, he was doing his duty in sending for assistance for the patient when he found her in danger; and 2nd, he happens to be a near connection.

Your obedient servant,

WILLIAM ROBINSON, L.K. & Q.C.P.

Newtownhamilton, October 18, 1879.

[Any person who avails himself of a point of law to escape payment of a claim which is justly due, is generally considered to be dishonest; but it does not seem as if boards of guardians held this view. Our correspondent ought, in law, to have insisted on receiving his requisition from the relieving officer, who is qualified to act as agent for the guardians; but we are doubtful that a dispensary committeeman could, according to law, act as the agent of the guardians, or make them legally liable for the fee for which they are plainly morally responsible, and which persons having any pretentions to be gentlemen would certainly pay.—ED. M. P. & C.]

LISBURN GUARDIANS.

SANITARY SALARIES.

MR. SPENCE wished to know what the duties were?

The Chairman said, some stated they were increased, and others said they were not.

Mr. Miller—Their duties are much the same as under the old Act.

The Chairman, having consulted the Clerk, said that that official had written to know what the duties were, but had got no reply.

Mr. Morrow said most of them were aware that at a former meeting of the Board a resolution was proposed by a member of the Board that the salaries of their medical officers should be £5 5s., instead of £1 as paid to them as sanitary officers under the old Act. That motion was allowed to pass, the majority of them remaining silent, knowing that the Local Government Board would make them reconsider the subject, as the salary was inadequate. They were now, under the direction of the Local Government Board, met to reconsider the matter. He would move that the salary of the officers of health be £10 per year in addition to their salaries as dispensary officers.

The Chairman wished to know if any member had an amendment to put.

Mr. Green—First of all, you had better send a telegram to the Local Government Board to ascertain if they would sanction £10. You know the whole thing lies in their hands. (Laughter.)

Mr. Brownlee moved as an amendment that the sum to be paid to the medical officers of health shall be £5 5s. per year, the same that was unanimously passed at a former special meeting of this Board.

The Chairman then read the section of the Public Health Act bearing on the subject, for the information of the members of the Board before they would record their votes.

The Chairman then put Mr. Brownlee's amendment to the meeting, which showed the following result:—

For Mr. Brownlee's amendment—11.

For Mr. R. Morrow's motion that the salaries of the medical officers should be £10, in addition to their salaries as dispensary doctors—10.

The amendment was therefore carried, and consequently the salaries of the "officers of health" remain as previously fixed by the unanimous decision of the board, at £5 5s., instead of £15, as paid to them as sanitary officers under the Act of 1874.

COLLON DISPENSARY.

ON Thursday the election of medical officer took place for Callon Dispensary District, in Ardee Union. There were three candidates in the field, namely, Dr. Collier, Dr. Healy, Monasterboice, and Doctor Smith, Dublin. After the first voting the contest lay between Drs. Collier and Healy. The former was elected.

ELECTION OF MEDICAL OFFICER FOR PORTUMNA.

A MEETING of the Portumna Committee was held for the purpose of electing a medical officer in the room of Dr. Samuel Coates, who resigned owing to failing health. The salary is £100 per annum, and £12 10s. per annum as medical officer of health, with vaccination and registration fees, making in globo about £200 per year.

The Chairman rose, and paid a high compliment to Dr. Samuel Coates, expressing much regret at the loss the district would sustain by the withdrawal of his services from the poor.

Three medical men applied for the vacant office, namely —Dr. Coates, Jun. (son of the respected medical officer who retired); Dr. Sampson, Woodford; and Dr. Daley, Limerick.

The election was put to the poll with the following result:—For Dr. Coates, 23; for Dr. Sampson, 4; and for Dr. Daley, 2.

PROPOSED REDUCTION OF SANITARY SALARIES.

REFUSAL OF SANCTION BY THE L. G. B.

AT the meeting of the guardians of Ardee Union a letter was read from the Local Government Board dealing with the question of reducing the salaries of the medical officers as consulting sanitary officers from £20 to £15 a year. The letter concluded as follows:—"If the guardians adhere to their resolution on the subject of the proposed reduction the board will feel it necessary to exercise the powers vested in them by the 11th section of the Public Health Act, 1878, and to issue an order fixing salaries for the medical officers of health commensurate with the duties which they will now be called upon to discharge." The guardians unanimously adopted a resolution declining to change the course they had approved of after mature deliberation.

ROSCREA GUARDIANS.

SHINRONE CORRESPONDENCE.

The following letter was read:—

Dublin, 30th September, 1879.

SIR,—The Local Government Board for Ireland forward, to be laid before the Board of Guardians of the Roscrea Union, a copy of a letter which they have received from Dr. Nixon, Medical Officer of the Shinrone Dispensary district, relating to his claim for payment of £2, certified by the magistrates as remuneration for his services in the examination of a lunatic; and in reference thereto, and to the resolution of the Guardians of the 18th instant, proposing to pay Dr. Nixon a sum of one guinea for his services in this case, the Local Government Board desire to state that when the amount awarded by the magistrates does not exceed £2 in respect of any one examination (section 14 of the Act 38 and 39 Vic., cap. 67), the Guardians have no power to alter the award.—By order of the Board.

A LUNACY GRANT.

There was a copy of a memorial from the same Union to the Chancellor of the Exchequer, stating that they are informed that Parliament has granted £83,800 as a contribution in aid of the maintenance of pauper lunatics in Ireland, and that some institutions have paid at the rate of 4s. per head per week, and that as harmless lunatics are now confined in the workhouse, they ask to be paid the forenamed capitation.

No action was taken in this matter.

VACCINATION DEFAUTERS.

The Clerk reported that proceedings had been taken at the Roscrea Petty Sessions on Monday against defaulters under the Vaccination Act. Two were fined, two dismissed, and two others, it appears, have been vaccinated. The presiding magistrate signed an order for £2, expenses of medical officers and other witnesses for the prosecution.

DROGHEDA UNION.

THE VACCINATION ACT.

Mr. Daley said that under the recent Act medical officers are entitled to a fee for registration of 2s. in every case of vaccination they perform. The medical officer of St. Peter's district explained to the committee that he is entitled to that fee in every case, whether the child of rich or poor parents, that comes to the dispensary to be vaccinateed. It appeared that some well-to-do people get their children vaccinated in that way and take the benefit of the Medical Relief Act intended for the poor. He considered it hard on the ratepayers to have to pay fees in such cases. In future, in order to check this practice, they would give publicity to the names of these parties.

MR. Moore—There were two cases in particular—one a very respectable farmer, holding 70 acres, and the other, a man earning £3 a week by his situation.

[We commend the proposal, and hope the Guardians will see the propriety of extending the publication to those persons who get gratuitous medical relief and medicine as paupers. The actual money loss to the ratepayers is much greater in the case of a long illness than in a vaccination. —ED. M. P. & C.

MORTALITY IN THE TROPICS.

THE average annual mortality of Pará, Brazil, is about 60 per 1000; in St. Kitts, W. I., the annual mortality rises as high, some years, as 74 per 1000. Throughout the West Indies the autumn is the most unhealthy season, and dysentery and yellow fever the most fatal epidemics. A correspondent of the *Southern Clinic* attributes the short lives of Europeans in the West Indies chiefly to exposure to cold and dampness, and to alcoholic beverages.

TAPE WORMS IN EGGS.

VARIOUS instances have been recorded of the discovery in hen's eggs of minute specimens of the *distoma ovatum*. They appear like a small speck, the size of a millet seed or a pin's head. It is believed by helminthologists that these will develope into one of the varieties of tape worm, and it is wise, therefore, to take eggs hard boiled or otherwise well-cooked. A writer in one of the late numbers of *Nature*, cites several instances where these parasitic bodies have been found.

TO READERS.

THE Editor will feel especially obliged by receiving copies of newspapers which contain any Poor-law or other intelligence of medical interest, in order that he may, if fit, republish it for the benefit of the readers of the *Medical Press*. Although twenty-one of the leading Irish newspapers are received at the Irish office, many things may escape notice which are deserving of attention. Newspapers should be marked, and addressed to Dr. JACOB, at the Dublin office of this paper.

ON CROUP.

By W. H. DAY, M.D.,

Physician to the Samaritan Hospital for Women and Children

Pathology—Nature of the Exudation—Two Varieties of Croup—1. The Mucous or Catarrhal—2. The Fibrous or Inflammatory Symptoms—Course and Progress of Each Form—Morbid Appearances—Clinical Characters of True or Typical Croup—Diagnosis from Diphtheria and Laryngismus — Treatment by the Vapour-Bath and Emetics—Mercury—Aconite—Tracheotomy.

AMONG the diseases of young children, croup occupies a foremost position, from the occasional suddenness of its accession, the rapidity of its course, and the danger attending its termination. Parents readily recognise the first symptoms, and are at once alarmed, and the child itself soon becomes terrified to a degree rarely seen in any other disease.

True croup consists in an inflammatory condition of the mucous membrane of the larynx and trachea, with the exudation of plastic lymph, which is quickly transformed into a firm adhesive membrane.

The inflammation has a tendency to seriously impede the functions of respiration, by extending down the air-passages, and producing troublesome and dangerous inflammatory complications in the lungs. The disease is generally acknowledged to be more frequent among male than female children. In my own experience, three-fourths of all the cases that have come under my notice have happened to males.

The varieties of croup enumerated by different authors are not clearly to be recognised in practice. We may fairly speak of two varieties. 1. The *mucous* or *catarrhal*. 2. The *fibrinous* or *inflammatory* (croupous membrane) form, according to the predominance of certain symptoms. The disease is modified with the age and constitution of the child, and spasm or inflammation may be more severe in one case than in another.

1. The *catarrhal* or *mucous* form is attended with hyperæmia of the mucous membrane, followed by excess of secretion and dyspnœa. The symptoms may be slow and insidious in some cases, and the catarrh and cough which precede the stage of development excite no alarm, till the hoarse voice and ringing cough announce the true character of the affection. In some instances we learn that the child has always had a delicate chest; that any exposure to damp weather brings on cold and cough; or it may be traceable to bronchitis. The temperature in these cases rarely exceeds 101°. Such a history is favourable to an attack of croup in a young child. In another case the symptoms are more sudden in their accession. Delicate, but especially young children, are sometimes seized whilst playing. In one case that came under my observation, a boy, æt. 8, left his play at 4 p.m., complaining of an uncomfortable feeling in his throat, and before six hours had elapsed, the symptoms were severe and dangerous. In another case, a strong and healthy child, æt. 2½, was seized with croupal symptoms at 11 A.M., and in eight hours afterwards they had attained alarming severity. Her parents assured me that she had slept well, and was very brisk and lively till the attack came on. In these cases laryngitis would seem to begin at once. Still, it will be found with few exceptions, that some catarrhal and feverish symptoms had been present a day or two previous to the attack of croup. If an active emetic be given at this stage, the breathing may rapidly improve, though the symptoms may recur and require similar treatment in the course of a few hours. In the majority of cases the following day will see the child in a fair way of recovery.

2. *Fibrinous croup* (*tracheo-laryngitis—croupous or membranous*) is the typical variety of the affection in its severest form. This is a more acute or intense inflammation; it is a true tracheitis, with exudation of plastic material, because the inflammation, affects not only the mucous membrane, but the fibrous tissue beneath. I will describe the course of the disease, according to my own personal observation. It generally begins with hoarseness of voice, and a peculiar harsh and ringing

Digitized by Google

cough, because there is absolutely no secretion, for the same reason there is a sense of constriction in the trachea. The respiration is hurried, and the inspiratory effort is long and crowing. In some cases a few hours will bring about the most severe symptoms; the pomum adami may be seen rising and falling very conspicuously with respiration, the eyes become swollen and bloodshot, the lips dusky, and the alæ nasi active; the skin is hot and dry, and the pulse small, hard and rapid. Unlike the variety which has just been described, the temperature may reach 103° or more. The child may put his hand to his throat, and in a deep hoarse voice, say or express that he cannot fetch his breath. At this stage the percussion note is clear over the thorax, the respiratory murmur is much diminished throughout the chest, and a loud sonorous râle attends it. No moist sounds have as yet been heard. As the case goes on, the croupal exudation becomes more organised, and clings to the larynx, when if the case progresses favourably, either the cast is thrown off, or resolution ensues with absorption. If the disease is extending, inspiration is now greatly impeded from blocking of the trachea by the false membrane; there may also be a tough piece of lymph in the trachea which cannot be dislodged. The larynx and muscles of the neck are very active. Notwithstanding the laborious and painful respiration, the child may, nevertheless, sleep soundly, though waking occasionally in terror. Thirst is generally present, and swallowing may be painful. I have known a child drink a large cup of milk half an hour before death. Still, an attempt at deglutition is generally painful, and brings on the cough. The pulse now becomes small and weak, and reaches 160; the crowing and hissing sounds in respiration increase, and the cough is incessant and painful. When the symptoms have attained this intensity, recovery is rare; the voice falls to a whisper, or departs altogether, and the cough is weak and suffocating. Sometimes, even at this stage of strangulation, shreds of lymph and false membrane are expelled by a violent effort and paroxysm of coughing; but the relief is only temporary, and the agony of oppressed breathing soon returns. The countenance now betrays the most painful anxiety; it is bloated and distressed, the tongue and lips are dusky, and the forehead and surface of the body are bathed in sweat. The pulse becomes feeble and thread-like, occasionally intermitting, or falling in frequency. The child is restless, and constantly turning about for relief, throwing the head back against the spine, or from side to side, while the fingers are bent in the palms of the hand. Agony is depicted in every feature. The struggle for breath goes on till the little sufferer dies convulsed, or passes into a state of stupor from which it never wakes again. A case that once came under my notice illustrates the sudden fatal termination not infrequent in this disease. The child, æt. 3, had been going on well for two days, and was sitting up in bed, playing with her toys and breathing tranquilly. In the night the respiration became embarrassed, and she died asphyxiated twelve hours from the period of relapse. After death a thin piece of partially detached croupal exudation was found lodged in the glottis, and this caused the fatal symptoms by occluding the larynx.

The false membrane found lining the air passages varies in extent; in one of my cases I found, on opening the larynx and trachea, three long and narrow pieces of lymph, one upwards of two inches in length, and the other nearly as long, between the lower border of the cricoid cartilage and the last rings of the trachea, without any extension to the bronchi. In this case moist sounds were heard in the chest on the second day of the illness; but they had disappeared on the fourth and fatal day. Near the level of the upper border of the cricoid cartilage were to be seen small tough fragments of lymph, not readily detached from the surface beneath. The mucous membrane was everywhere red, and in places vividly so; but there was not any evidence of submucous effusion, for it must be remembered that the connective tissue of the larynx is very small in quantity. In other cases lymph may be observed throughout the trachea, and the mucous membrane may be pale, except in isolated patches where it is red and vascular. The false membrane varies much in form and consistency, sometimes it is cylindrical in shape, and loose, or adherent to the mucous membrane beneath, from which it is not readily separated; in other instances it is moulded to the shape of the bronchial tubes where the inflammation has extended into the lungs, and in these cases the efforts of vomiting fail to bring away the source of irritation, and the danger to life is thereby increased. When the false membrane is loose and fragile, it is easier of expectoration; and it is these cases that have the best chance of recovery, particularly if limited to the larynx and trachea, the lungs not being involved in the inflammatory process.

Of late so much difference of opinion has arisen on the pathology of croup that we are induced to ask what is understood by the term? Until recently it has generally been regarded as a local disease, an inflammation of the trachea attended with the formation of false membrane (croupal exudation), though the practical physician most commonly recognises the disease by the spasmodic closure of the glottis, the prolonged and crowing inspiration, and the fear of impending suffocation. If to these symptoms are added fever and inflammatory excitement, he has no doubt whatever that he is dealing with a case of genuine typical croup, such as had been known before diphtheria was recognised and distinguished in this country. To me it appears that croup, whether simple or membranous, is a totally different disease from diphtheria, and that they only approach any degree of relationship when the latter disease has invaded the larynx, and then the symptoms due to obstructed breathing are much the same in both cases.

We constantly meet with genuine croup of an acute and local inflammatory character, leading to the well-known false membrane in the trachea and larynx, as described by the old-fashioned authorities. It seems impossible that we can mistake this true croup (which we have been in the habit of meeting with all our lives) for the peculiar membranous inflammation of the trachea sometimes seen in cases of diphtheria. It is well to glance at some remarkable points of difference in the two affections.

1. True croup is prone to attack the healthiest children, and in districts where diphtheria does not prevail. (*a*) (*b*)

2. True croup is apt to come on very suddenly, and in cases of recovery the general health is rapidly re-established, as compared with diphtheria.

3. In diphtheritic croup the disease is of a well-marked constitutional character, and is always accompanied by great depression and nervous symptoms.

4. Croup is a local disease; diphtheria is a constitutional affection, in which the kidneys and intestines may be involved. Croup is neither infectious nor contagious; diphtheria is both.

5. The cases that recover from diphtheritic croup are few, and the convalescence is not only very slow and

(*a*) There are many instances on record of a whole family of children dying of diphtheria in the course of twenty or thirty days. Malignant epidemics of this nature have prevailed in this country since 1857; but we have never known of three cases of genuine croup happening at one and the same time to a single family, and we have never known them last so long. The recurrence of diphtheria in the same house has been noticed over and over again, and traced to bad drainage, proving that the power of contagion lurks and lingers about, ready to seize on any person lowered in health or susceptible to its influence. The disease is most prone to attack delicate children, whose homes are badly ventilated, and where sanitary precautions are neglected.

(*b*) It would be impossible for the want of space to enter here into the long and vexed question as to whether the croup of Home and Cheyne in this country is the same disease as the "diphtherite" of Bretonneau. I can discover nothing to warrant this conclusion, for, if identical, surely modern writers would have had their attention directed to the resemblance in the course of long and varied experience. Diphtheria is a disease only recently described with precision; as soon as attention was directed to it physicians at once recognised a new disorder, both in its anatomical and clinical features, entirely different from anything they had previously seen, and presenting symptoms at complete variance with the so-called inflammatory or true croup.

Digitized by Google

tedious, but the throat affection is usually preceded by a characteristic membrane on the palate, and the prostration is always great. Partial loss of voice, fœtid breath, swollen neck and glands, diminution of muscular power, paralysis of the muscles of deglutition, and albuminuria are common in diphtheria; but they are not witnessed in inflammatory croup.

6. Between croup and diphtheria there is also another very important diagnostic difference; diphtheria generally begins in the pharynx, croup in the larynx. (*a*) The false membrane found in the larynx in cases of genuine croup is quite different from the leathery or yellowish-grey exudation found on the tonsils, in the larynx, and bronchial tubes in cases of diphtheria. The pathological differences between croup and diphtheria are open to further contrast. In the early stage of croup there is an increase in the vascularity of the affected membrane as in severe catarrh, with a trifling amount of inflammatory exudation. This is succeded by fibrillation of the exuded lymph, which, with the new-formed cellular elements, becomes transformed into the characteristic *false membrane.* Its consistence varies, being in some cases tough, in others soft and amorphous, and easily removed from the mucous membrane beneath. In the larynx and upper part of the trachea where the inflammation is most acute the exudation is croupal or membranous, and is very characteristic of true croup, but in the lowest part of the trachea and diverging bronchi, there may be nothing more than a scanty superficial layer of mucus.

"It is difficult in many cases to draw any line of demarcation between the histological changes occurring in diphtheria and those of croup. In diphtheria, however, the sub-mucous tissue usually becomes more extensively involved, so that the false membrane is much less readily removed. The circulation also often becomes so much interfered with that portions of the tissue lose their vitality, and large ash-coloured sloughs are formed, which, after removal, leave a considerable loss of substance." (*b*)

7. If croup were identical with diphtheria, it seems to me that the operation of tracheotomy would rarely succeed; whereas it is often successful when false membrane has blocked up the tracheal tube, and has been removed from time to time after the operation.

The following affords an excellent illustration of the comparison between croup and diphtheria:—

Dr. Sansom has related a case of pharyngo-laryngeal diphtheria with albuminuria, in a female child four and a half years old, where tracheotomy was resorted to on account of dyspnœa and embarrassed breathing. White patches were observed on the pharynx and right tonsil. The edges of the wound were covered with diphtheritic false membrane, and sloughing proceeded, accompanied with extreme prostration. A wound of the ring finger of the right hand was covered by false membrane, and from this wound ulceration extended, and involved a part of the right hand. During the following week there was little change, then extreme adynamia ensued, pneumonia attacked the bases of both lungs, and the child died sixteen days after the operation of tracheotomy. After death the larynx was covered with false membrane, the tissues around the tracheal wound were infiltrated, and there was sloughing of the soft structures. The kidneys were in a state of acute nephritis, and the lungs showed diffused broncho-pneumonia. (*a*)

The treatment that would put at end to catarrhal croup would hourly aggravate a case of diphtheria and hasten death. This alone is sufficient to convince us that the two diseases are essentially different. A child is put to bed in an atmosphere of steam, suffering from acute croup, and after the action of tartar emetic and perhaps a grain of calomel, the alarming symptoms gradually subside. This is never seen in a case of diphtheria—the nervous prostration which invariably accompanies it would be aggravated, and life probably sacrificed, by the adoption of such treatment.

(To be continued)

(*a*) "My idea of the problem to be solved is, in fact, this:—It must be admitted that the diphtheritic poison is capable of giving rise to a plastic inflammation of the larynx, apart from the existence of any similar affection of the pharynx. But there is good reason to believe that during epidemics of diphtheria the cases in which this occurs are in the highest degree exceptional. If, therefore, it can be shown that in the practice of a general hospital the cases of plastic laryngitis, of uncertain origin, bear a large proportion to the total number of cases of diphtheria, there will be a strong probability that the majority of the former cases are dependent upon some other cause than the diphtheritic poison."—"Diphtheria and Croup," by W. H. Lamb, M.B., and C. Hilton Fagge, M.D., *Guy's Hospital Reports*, 1877, p. 345.

SANITARY FALLACIES. (*b*)

By WILLIAM HENRY CORFIELD, M.A., M.D. Oxon, M.R.C.P. Lond.,

Professor of Hygiene and Public Health, University College, London, &c.

AFTER a few introductory remarks Prof. Corfield said: The history of sanitary fallacies was intimately bound up with the history of the art of preserving the health. Hippocrates might fairly be said to have been the founder of the rational method of studying the causes of disease—a method which, 2,300 years after his time, we found to be the correct one. But it was not long before a great fallacy arose and divided the disciples of medicine into two rival schools, of which Herophilus and Erysistratus were the principal lights.

In the Middle Ages, according to Dr. Davies, "reason and experience were wholly discarded, the use of ordinary means was completely eclipsed by the miraculous power of tombs and relics, of saints and martyrs, of holy water, charms and amulets, and each and every portion of the human frame was assigned to the guardianship of different saints."

This grand fallacy, the mistaken union of theology and medicines, continued so late as the time of Henry VIII., who, in 1511, ordered that physicians and surgeons should be examined by a Bishop or Vicar-General, with the assistance of "such expert persons as they shall think desirable."

After instancing the fearful ravages of the Black Plague in Europe, the lecturer said that against all sanitary improvements the argument that things had gone on in the same way for years had always been urged as the defence of doing nothing; but people forget that those who were living in the midst of general unsanitary conditions were in a worse plight than people living in the crater of an extinct volcano.

An important fallacy existed regarding the communicable fevers. Without entering into the vexed question of the nature of the poison of such diseases, he merely pointed out the belief that these diseases might originate anywhere, at any time, under suitable conditions, was now almost universally scouted with regard to the majority of them. How many persons there were who believed that small-pox or scarlet fever, measles or whooping-cough, arose independently of previous cases of these diseases, and not a few, supported by the weight of great authority, who believed in the spontaneous origination of the poisons of typhus and enteric fevers, of diphtheria and of cholera. It was a very old and often exposed fallacy to argue against the use of a thing from the abuse of it, and people still talked and wrote as if the water-carriage system and the conservancy system, applied to the removal of refuse matters, stood on the same footing. Whereas the one was a correct and the other a false principle, and the mischiefs

(*a*) "Croup and Diphtheria: A Contrast." Medical Society's Proceedings. Vol. iii. 1875-77. Page 105.

(*b*) Read before the Sanitary Congress, under the auspices of the Sanitary Institute of Great Britain and Ireland, at Croydon, October 23, 1879.

Digitized by Google

which had been traced to the water-carriage system were occasioned by its abuse. The fallacy of having air-tight sewers was fully exposed by the Health of Towns' Commissioner in 1843. Another important matter in which we were liable to be led astray by false principles was the supply of water for domestic purposes. Not long ago, a man, deservedly eminent, told the public that water analysts and medical officers of health had all gone wrong about water; that the small quantities of organic matter that were discovered in water were of no importance; that all water, however pure, was contaminated with organic matter so soon as it got into our mouths; that the greater part of our food consisted of organic matter, and that it was ridiculous to condemn a drinking water because it contained small quantities of organic matter.

The obvious fallacy of such arguments must be patent to all who thought on the subject, but they were calculated to do a vast amount of mischief among the unthinking. The fallacies connected with dietetics were very numerous. There was a curious fallacy about the nutritive qualities of gelatine, it being proved to be an important article of diet; and it was to be hoped that the nonsense about invalids being starved upon jellies and port wine would disappear from our treatises. As to alcohol, there was no question in his mind that the drinking of alcoholic liquors did far more mischief than any other habit whatever. One fallacy in connection with this subject was this. The man who drank his glass of grog at night often defended himself upon the plea that the spirit was diluted, and that the mixture did not contain more alcohol than the few glasses of wine usually taken at meals; but the spirit and water thus taken was taken under circumstances which rendered it most potent for mischief. A highly diffusible liquid, it was taken into the stomach when digestion was over, and when the stomach was nearly or quite empty. It was absorbed directly, unaccompanied by any nutritious substances, into the blood, and was enabled to act in the most prejudicial manner, not only upon the liver, producing the gin-drinker's liver, which meant death, but also degeneration of all the tissues of the body. With regard to tobacco there was a curious fallacy abroad. Although the excessive use of it, as of tea or of coffee, or of any substance that acted directly upon the nervous system, was injurious in various ways, there was no evidence that the moderate use of it was pernicious. Sir John Sinclair, who took pains to investigate this subject carefully, came to the following conclusion in his admirable "Code of Health:" "It does not appear that a temperate use of tobacco can be considered as an obstacle to longevity." On the contrary, the evidence was very distinct that among the old persons available for the investigations the great majority were smokers, so it might, indeed, be argued, with some show of reason, that smoking was favourable to longevity. He, however, expressed his agreement with the late Dr. Parkes that smoking is an injurious and undesirable habit for growing lads. Referring to the fallacies in connection with small-pox and vaccination, he deprecated the attempts to persuade the people that vaccination was not a preventive of small-pox. The Swedish statistics, which had always been pointed to as strongly in favour of vaccination, had been recently manipulated with the view of proving the reverse. He had before him the statistics for 124 years. In the 61 years before the practice of vaccination there was only one year in which the deaths in Sweden from small-pox were less than a thousand, and there were nine years in which the deaths were over 10,000. In the 63 years during which vaccination was practised there were 48 years in which the deaths from small-pox were under a thousand, and in no year did they reach 10,000, or even 3,000. With regard to the class of contagious diseases partially dealt with by Act of Parliament, whatever well-minded people might say to the contrary, it was not their prerogative to visit the sins of the fathers upon the children. He would re-echo the works of Dr. Farr:—"Morality, it may be hoped, will be inculcated by higher agencies than enthetic diseases." Statistical fallacies were sometimes of a serious nature. They were told that in spite of sanitary improvements the death-rate remains the same. Considering that "the mortality of the City of London was at the rate of 80 per 1,000 in the latter half of the 17th century, and 50 in the 18th, against 24 in the present day," according to Farr, this statement seems rather audacious. In conclusion, he said if they wished to make the public believe that they were in earnest about sanitary reform they must be united amongst themselves, and not go about wringing their hands as some did, because others than themselves had a share in the good work.

Clinical Records.

CARLOW COUNTY INFIRMARY.

Foreign Bodies in the Ear extracted by a Hair-pin.

Under the care of Dr. E. A. RAWSON,

Surgeon to the Infirmary.

CHILDREN frequently put stones or other things into their ears and nostrils, and it is often an exceedingly difficult, tedious, and painful operation to extract them. I have used all kinds of forceps, and crooks, and wire loops, with varying success, but the operation is always tedious, and blood is almost always drawn.

I was utterly beaten in one case lately. A boy, æt. 9, pushed a good-sized white stone into his left ear. It could be easily seen. I caught it with all kinds of implements over and over again, but no amount of force or manipulation could dislodge it. I sent him to Dublin, where several eminent surgeons tried their hands on him, without success. He returned home, an abscess formed, and one morning the stone fell out.

In July last a little girl, æt. 10, put some stones into both her ears. I tried the usual instruments, and only succeeded in drawing a good deal of blood. I had that morning picked up a hair pin—a large one; the kind ladies use for heavy coils of hair. I tried it, passing it along the upper side of the meatus, and when, by the feel, the bend was beyond the stone, depressed it slightly and withdrew it; to my gratification it brought out two little stones. As the child was crying, and complaining of pain from my rooting with the other instruments, I left her alone for two days, and then used the same hair-pin in the same manner, on the other ear; and on this occasion also, on withdrawing it, I found it clasping two stones. The time of the operation was about five seconds. There was no blood and it was painless.

Although a hair-pin may have been frequently used before, I have not seen it mentioned, and it is such an exceedingly simple and useful little instrument that I hope many will try it.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

THE Second Meeting of the Session was held on Friday last, when, on taking the chair, the President announced the deeply melancholy news of the death of his immediate predecessor in office, Mr. Callender, F.R.C.S. Mr. Callender was on his return voyage from America.

Dr. SOUTHEY on

TWO RARE CASES OF ACUTE RHEUMATISM.

CASE I.—F. G., æt. 23, first attack. Admitted into St. Bartholomew's Hospital on sixth day of his disease. The symptoms of rheumatism were well marked; there was pericarditis; and patient had a temperature of 103° Fahr., respiration 24, pulse 96. He was a pale, poorly-nourished

Digitized by Google

man, with a tremulous tongue; by his own account, and that of his family, temperate.

Course and Progress.—The pericardial effusion increased, and was well established by its ordinary physical signs. Upon the sixth and seventh days of his illness, the temperature was maintained at 104°, and remained high between 102·4° and 103·8°, up to the eleventh day of the disease. All this time he complained less of pain than of sleeplessness; but on this date the symptoms of typhoid or cerebral rheumatism supervened. His manner of answering questions was altered; he was abrupt in speech, and incorrect in his statements. He lost the pains in his joints, and could move his hands and legs about, but with well marked loss of muscular co-ordinating power. This delirium, with tremor and loss of muscular power, was succeeded by some choreic jactitation and subsultus, on the twentieth day of the malady, when the case, if seen for the first time, might easily have been mistaken for one of typhus. The treatment hitherto had been milk, beef-tea, pudding, eggs, and 4 ozs. of brandy per diem, necessitated by the patient's feeble and dicrotic pulse. For the first few days simple saline medicines, and afterwards sp. of chloroform, cardamoms and peppermint; but succus conii, with bromide of potassium—half-an-ounce of the former to half-a-drachm of the latter—were now, on the twentieth day, given every four hours, and an ice-bag was applied alternately to top of his head and nape of his neck. As he still continued sleepless on the twenty-first day of his illness he was ordered a chloral draught up to 30 grains. This was succeeded by four hours good sleep. Twenty-second day of disease, quite conscious and rational; complains once more of the rheumatic pains in his joints. Hands tremulous, he lay like a log in bed, without any muscular power to help himself. The ice-bags, bromide and conium, were continued for four days, during which period the temperature gradually came down. The respiration became fuller and less frequent, and the pulse regained power. They were then discontinued. The patient recovered quickly and completely; was up and convalescing on the twenty-eighth day of the illness, and discharged some ten days later.

Remarks on Case I.—This was a typical case of cerebral or typhoid rheumatism, complicated, it is admitted, by pericarditis, attended by such a temperature as often is encountered in acute rheumatism thus complicated. The cerebral symptoms do not occur when the temperature is at its highest on the sixth and seventh days, but on the twelfth day, when the temperature at its recorded highest was 102·8. What I wish to point attention to, is the peculiarity of the delirium and the whole of the nervous symptoms. They are quite characteristic of the disease; have been observed by all who have put any similar cases upon record, but have been attributed to alcoholism, and to nervous systems damaged by habits of intemperance. In my opinion alcohol is not found guilty of them, and has really nothing whatever to do with them. It is only a superficial likeness to delirium tremens, which is presented. There is delirium with general tremors. This is, however, not a noisy, busy, delirium, with horrors and delusions of an active kind. There is a coma vigil sort of state, in which the patient lies muttering deliriously, and constantly is talking to himself. If you arouse him he wakes up apparently all right, says he has no pain, feels very well, and answers your questions in a manner that might throw you quite off your guard. Every statement he makes may be incorrect, and is wholly untrustworthy. Then the muscular tremors increase to choreic jactitation; there is constant twitching and subsultus of the muscles, and finally, this condition, as in another case which I watched, and which is recorded in a volume of this Society's "Transactions," is succeeded by a state of general muscular paralysis, whether from asthenia, or actual palsy of the motor powers, I know not, but this I do know, that they lie like logs in a bed, and cannot help themselves a bit. This case recovered, and I attribute his recovery to the treatment pursued. The bromide and conium may have tranquilised the spinal centres, as Dr. Greenhow thought it did in a case in which he tried it; but the ice-bag to the head and neck is, I believe, good treatment; safer, because less fatiguing and equally as efficacious, I think, as the cold plunge or wet sheet. But neither of these strong measures was indicated by the patients' pyrexia, which was not hyper.

Case II.—H. C., æt. 20, admitted into Faith Ward for acute rheumatism. Third attack within two years. The aches and pains began gradually for four days. She felt them, but was able to get up. For last five days had been confined to her bed with pain and swelling of several joints.

Patient's State on Admission 5th day.—Joint inflammations well marked. Mitral regurgitation, with very little hypertrophy, No cardiac pain. Physical signs were attributed to old endocarditis. Temp. 96 only; resp. 28; pulse 96; urine scanty, high-coloured, sp. g. 1020, containing a little albumen. Her tongue had the usual white fur, was moist, and her appetite was *nil.*

5th day of disease.—Evening temp. 102·2; resp. 40; pulse 100. As she was very sleepless and worn out, she was ordered a draught containing Chloral gr. v.; pot. chlor. gr. v.; and mist. camphor. 6ts. horis; and a milk arrowroot and beef-tea dietary.

Course and Progress.—During the 6th, 7th, and 8th days the temperature gradually abated. On the 7th the bowels acted spontaneously; the urine was still very slightly albuminous; but her pains were better, tongue cleaner, and there were no physical signs indicative of any serious complication. On the 9th day of her illness, after a fair night, she complained that her right knee was now painful. Her face was pale and haggard-looking, and her lips were livid enough to make me examine her carefully. There was no friction rub, no increase of præcordial dulness, no evidence of any pleural effusion or of anything in the thorax to explain her aspect or the change in her. Her temperature was 101·2; resp. about 40; pulse small, feeble, 120. Only six ounces of urine had been passed through the previous 24 hours. This was of sp. g. 1018, and contained a considerable quantity of albumen; quite a third. There was no fulness in the bladder region, for I tapped over it; no retention of urine. I stopped the chloral draught, wondering if this might have had any bad effect upon her, and because her pulse was so feeble, ordered her two ounces of brandy and a citrate of potash draught with ammonia and nitric ether. Now, if I had been treating her rheumatism with frequent doses of salicylate of soda, I should have doubtless attributed her symptoms to this substance. I called my house-physician's special attention to all the symptoms of gravity about her, and expressed my fear that she was going to die; what of I could not tell. That same afternoon she suddenly complained of a fresh pain in her epigastrium, and vomited some quantity of green bilious fluid—uræmic vomiting?—and perspired very profusely. Her temperature was taken again at 7.30 p.m.; it was then 102·4, not a high temperature, you must admit. Her respiration was only 32, but hardly any pulse could be felt at her wrist. Asked if her feet were cold, she said, no, they are burning hot. The nurse felt them and assured me they were only comfortably warm. She was sat up in bed; the pain referred to the bottom of the stomach became very acute, and the house-physician was called to her, who thought she must have pericarditis, and ordered a blister for her. Her face now was deathly pale, her eyes wild and staring, and she pointed excitedly to her epigastrium, asking "can no one give me relief for this pain." The house-physician was preparing to give her a subcutaneous injection of morphia at 12.15., when she died. As death was imminent, and the last observation had shown so much albumen in the urine, I am glad that this was not done. It will at least not be found guilty of her death.

Post-mortem 28 hours after Death.—No effusion in pleura, pericardium or peritoneum; no appearance of recent lymph anywhere. Very slight old white patch in pericardium over root of the aorta. Lungs normal, but congested. No clots in pulmonary artery. All the heart's cavities distended with greenish and much decomposed soft clots. Heart's muscular substance was of a dirty brown colour. The muscular fibres were rather granular-looking under microscope, and did not exhibit their normal distinct striation; but may not this be attributed to the rapid decomposition which had set in. Aortic valves normal; mitral valve covered with small vegetation upon its auricular surface; mitral orifice somewhat narrowed. Spleen and liver large and soft. Intestines filled with greenish yellow, slimy mucus similar to that vomited during life. Kidneys swollen, pale, and soft. All these glandular organs then present appearances of general parenchymatous swelling, similar to those observed in persons who die, as it is supposed, of hyperpyrexia.

Remarks.—I have prepared none. I prefer the case should speak for itself. To me it is an intensely interesting one. It furnished a fact I had been long looking out for—sudden death in rheumatism, with appearances suggestive of hyperpyrexia, but without any remarkable temperature reached or

Digitized by Google

observed. She died of asthenia, or heart failure, with gradually failing pulse, until this could not be perceived at the wrist. The appearance of the heart did not, to my knowledge of pathology, suggest carditis the very least. That of the kidneys is no more than is found in any acute disease that dies; pneumonia or fever, for example. To explain it I can only offer what will be accepted as proof of my ignorance—the hypothesis—that in rheumatism there sometimes suddenly takes place a great change in the blood itself, which makes this circulate everywhere with difficulty. It will not undergo its proper oxygenation changes in the lungs; it fails to carry the requisite oxygen everywhere, and to circulate properly. If the blood stasis occurs in certain nervous centres hyperpyrexia may attend this local accident. There have been these two clinical symptoms—extreme pallor of the face, and lividity of the lips. In other fatal cases of rheumatism which I have seen, I know them now to be of almost fatal omen, and wish to direct the attention of the profession to them.

Dr. THEODORE WILLIAMS wished to know if an examination of the blood had disclosed any material change in the appearance of the red corpuscles.

Dr. MACLACHLAN considered the case a peculiarly interesting one, but could not entirely agree with the conclusions reached by the author of the paper. He was of opinion that hyperpyrexia does not cause death, but is concomitant with it. Some particular portion of the nervous centre being affected by the rheumatic poison, hyperpyrexia is induced, and death is hurried on under the action of the morbific agent. He pointed out that the signs recorded were those of carditis and pericarditis.

Dr. SOUTHEY, in reply, said that no examination of the blood had been made. The fluid was in a very decomposed and clotted condition, and no analysis of it had been performed. Any change observed would, he thought, possess no elucidative value, nor could he attach any importance to the alteration of the corpuscles. Thickened patches, evidently of old standing, about the base of the heart, seen on post-mortem examination, indicated the existence of pericarditis in life, and carditis followed very considerable change in the muscle, whereby it had lost its striæ.

Dr. GEORGE WILKS (of Ashford) communicated the case of J. O., who was struck by lightning on June 8th, 1878. He was struck while staying to empty his bladder by a willow-tree close to the window of a shed in which his three fellow-workmen had just taken shelter from a violent storm of rain. The lightning rushed in at the door and out of the window, which it blew into the field. The three were scared for a time, and on recovering sought their companion. They found the tree partly denuded of its bark, and the patient's boots standing at its foot. The patient himself was lying on his back two yards off, and though he was fully clothed previously, he was now *naked*, with absolutely nothing on except part of the left arm of his flannel vest. He was conscious, but much burnt, with a badly-broken leg. The field around was strewn with fragments of the clothing; the clothes were split or torn from top to bottom, the edges of the fragments being often torn with shreds or fringes: they only showed evidences of fire where they came in contact with metal, such as his watch, or the buckle of his waist-belt. There were no laces in the boots; the left boot was torn and twisted into fantastic shapes, but the sole was uninjured, and there were no signs of fire upon it: the right boot had the leather much torn and the sole rent and burnt. The watch had a hole burnt through the case, and the chain was almost entirely destroyed. The stockings were split down the inner side; the hat was uninjured. The patient stated he was struck violently on the chest and shoulders, became enveloped in blinding light, and was hurled into the air, coming down on his back "all of a crash," and never losing consciousness. Three hours later he was seen by Dr. Wilks; he was then quiet, but complained of a little pain in each leg, and of a universal sense of burning, fiery, heat. He was also deaf. The hair of his face was burnt, and the body was covered with burns, superficial on the chest, but deeper on the abdomen and right thigh. Down each thigh and leg was a broad crimson indurated band of burning, passing along the inner side of the knee, and ending below the left inner ankle, and at the right heel, a lacerated wound, with a comminuted fracture of the os calcis. The bones of the right leg were fractured, and the tibia protruded through the skin in the course of the burn. The fracture was reduced, and slung; the burns were treated with carron oil, and milk diet was ordered. After the eighth or ninth day his progress was uninterrupted, but delayed by the slowness with which the heel recovered. He was discharged twenty weeks after the occurrence. Dr. Wilks remarks on the almost complete unanimity of the nervous system, and on the probability that the clothes being wet acted as good conductors, and so diverted the electric current from the great nervous trunks, and so saved the man's life. The various articles of clothing, the man's watch, and portions of the back of the tree were exhibited to the Society.

Sir JAMES PAGET said he had held possession of the clothes (exhibited) for some weeks; seeing them, he felt sure that any one would conceive it impossible that a flash of lightning could do what had been done in the case. He considered the explanation of the man's preservation from instant death, as given by Dr. Wilks, the correct one—as being due, that is, to the dampness of the clothes in contact with the body. It is worthy of note, continued Sir James, the course taken by the lightning flash, as showing the possibility it has of completely stripping a body by clean sweeps. The irregularities in the direction of the rents are to be attributed to interference with the direct passage of the current by dry patches of clothing. This is particularly noticeable in the boots, one of which, at the time of the accident partially raised from the ground, is much more irregularly injured than the other. The watch exhibited proof of the same peculiarity. Sir James further added that, in a tree close by the place where the man was, there remained marks to show that the flash had pursued a path down the moist *liber* of the trunk. He had discussed the question with Professor Tyndall, who endorsed the opinion he had formed, and who, in common with many other men of science, regarded the case as quite unique. He would add that he considered the man had been excellently treated by Dr. Wilks.

Dr. BROADBENT suggested that the stripping of the body may be explained on the assumption that a body of steam had been rapidly formed, and the passage of the flash had been influenced thereby.

Dr. ALTHAUS remembered reading of a similar case some twenty-one years ago, recorded in the "Philosophical Transactions of the Royal Society." He attributed the effects produced by electricity to mechanical force merely of the discharge. This is known, he added, to be very great. He could not but think it strange that the man exhibited no paralysis or affection of the nerve centres. Possibly the man was a bad conductor of electricity. Some people were ill, some well, endowed in this respect, and it is undoubtedly true that, as a rule, the nerve centres are materially affected by such accidents.

Dr. HEWAN narrated the case of a dog belonging to a friend of his, twenty-one years ago, on the West African coast. The animal was lying beside its master one night, when it was (presumably) struck dead by a current of electricity which passed through the house by a central lamp suspender. The animal was discovered to be quite dead after the storm, which raged only a short time. It exhibited no external evidence, however, of such a death.

Mr. HULKE did not see anything in the narrative of Dr. Hewan to prove that the dog *was* killed by lightning at all.

Mr. GEO. LAWSON exhibited a

SPECIMEN OF A CASE OF CANCER OF THE BREAST WHICH HAD FOLLOWED ECZEMA OF THE NIPPLE OF LONG STANDING.

The patient had suffered from eczema of the nipple for four years, and during that time had been under the care of four different physicians. In July, 1878, she consulted the late Dr. Tilbury Fox for a very chronic eczema of the nipple, which involved the skin around it for an area of about one inch. She had tried all the usual remedies, and had also taken arsenic largely. At this time Mr. Lawson saw the case with Dr. Fox, and examined the breast specially to ascertain if there were any indications of cancer, but he was unable to discover any. The skin was movable over the breast, and the breast upon the muscle. There was no enlargement of the axillary glands. The eczema was relieved, but never cured. In July of this year she came under the care of Mr. Lawson, and he was then struck with the great change which had taken place. The breast was now large and hard, with the nipple much retracted, and the skin around the nipple adherent to the parts below. There was also an enlarged

Digitized by Google

gland in the axilla. On the following day the patient saw Sir James Paget, and he concurred in the advice that the breast should be removed. The operation was accordingly performed, and the patient made a rapid recovery. *Remarks.*—Mr. Lawson said that one of the surgical questions of the day was whether we may consider intractable eczema of the nipple the precursor of scirrhus of the breast. The cases related by Sir James Paget and Mr. Butlin have established the fact that scirrhus of the breast frequently follows a condition of the skin which closely resembles eczema in its general characters. There was some doubt as to whether this so-called eczema was indeed true eczema; whether it was not rather a new growth with some of the superficial characters of eczema, but which differs from it in its microscopical structure. The important and practical question was whether in cases of eczema of the nipple which has resisted for a length of time all treatment, we are not justified in advising that the breast should be removed in anticipation of a disease which does not then exist. In one case he said he had removed the greater portion of a tongue because the gentleman had suffered from ichthyosis of that organ for eighteen years, and he had found that all the recorded cases of ichthyosis had terminated in cancer, either before or shortly after the disease had reached that age. He had also frequently excised an eye which had received a dangerous wound in anticipation of sympathetic ophthalmia occurring in the sound eye, feeling that it was better to save one eye than run the risk of losing both. The same principle of treatment, he thought, might be fairly applied to cases of intractable eczema of the nipple, if we could thoroughly establish the fact that in the majority of such cases the disease is followed by cancer.

Dr. THIN explained that he had purposely avoided detailing the differential characters of the sections he had made; to do so would unduly extend the limits of the communication, and, further, he hoped soon to lay all the results of his investigations before the profession. He regarded the disease as not an eczema, the appearance of the skin under the nipple being misleading. The absence of the intolerable itching attendant on eczema went to prove this. In his opinion, cancer, in such cases precedes eczema. The epithelial element at the mouths of the galactophorous ducts, first undergoes pathological changes, and thence the cancerous matter spreads, infiltrating the cellular tissue about, and proceeding gradually into the substance of the gland. Consequently, to treat a patient in this condition, only for the skin affection, involves the gravest error, for during the time attention is being given to a comparatively trivial complaint, the deadly disease is making certain progress in the lactiferous vessels, progressing by certain stages to the axilla and mamma. Such a course, he declared, is a common result.

Mr. BUTLIN felt that he must take the responsibility of the term eczema. He did not, however, intend to imply skin disease solely and precisely, by it. He had seen 4 or 5 cases in which the nipple presented the same indications as in the one under discussion. In one case, under observation, at St. Bartholomew's Hospital, it was not so, however. In it there was no discharge, either from surface or from ducts, and the organ on the affected side was less elastic and firm to the touch than that on the opposite side of the body. Though not eczematous, still the condition of the nipple and ducts, even in this, agreed with those of the other cases. In it, only portions of epithelial structures were involved by disease; but in the others all the ducts were so affected.

Sir JAMES PAGET agreed that it might be unwise to give the term eczema to the condition of the parts, and that grave danger of a cancerous issue was involved therein. He was compelled to differ from Dr. Thin on clinical grounds. In one case which resisted treatment during eight months, a cure was effected in eight more, and no cancer was developed in the breast. Such cases, however, are in danger of becoming cancerous; and similarly, in continued icthyosis, the tendency is to a cancerous disease of the tongue, although it would be wrong to diagnose cancer at the outset. In illustration of the principle he was expounding, he would instance the proved possibility of cancer developing in scars left by burns, even twenty or thirty years subsequent to the original injury. The number of cases in which cancer may appear is very large, and at present we have no accurate knowledge, either of the causes, or the time which determine its growth.

Mr. JONATHAN HUTCHINSON.—The general nature of cancerous disease is a most important subject. Some years ago he had contributed a paper on what he termed "the successful cultivation of cancer," for the purpose of drawing attention to the conditions favouring its development. He considered the term eczema correctly employed by Sir James Paget and Mr. Butlin, seeing that it admitted of a wide signification, and that the nature of the affection so called varied much under different conditions. Probably, in some cases narrated, there is simply, at first, a local disease at the nipple, which disturbing the local nutrition, and setting up irritation lasting to the observed cancerous period of life, may eventuate in production of the fatal disease. With them, may be other cases in which a process, more nearly allied to cancerous degeneration, sets in from the first. In case the eczema resists treatment, then is it sufficiently early to initiate special precautionary treatment. Such resistance to ordinary treatment must strengthen the suspicion of cancer. He agreed with Mr. Lawson as to the advisability of an early removal of white patches on the tongue. It is to the interest of the patient to resort to early operative procedures for the eradication of certain disease. Mr. Hutchinson related that in one of his cases a patient operated on in an early stage, is at present, after four years, quite well.

Mr. HENRY MORRIS supported the statements already made, by citing two cases of reported eczema, followed by cancer of the breast. The condition of the areola had existed too long not to have preceded the cancer; in one case six years. He was consequently inclined to oppose the view held by Dr. Thin. He remembered an instance of similar external disease in the O.P. department of Middlesex Hospital; but here there was no suspicion of cancer. The nipple in a girl 18 years old, had been some time ulcerated. By her account, she had suffered from cancer "of the mouth of the breast," but no sign of the disease could be detected. Possibly the practitioner without, might have deemed its removal necessary. Mr. Morris found much difficulty in reconciling the result of his own observation with the theory proposed by Dr. Thin, and could not, therefore, advise early removal of the diseased organ in such cases. Similarly, he considered icthyosis did not always indicate the operation for amputation of the tongue. Out of 500 cases seen, during six years' practice, he had observed only two in which cancer of the breast followed ulcerated nipple.

Mr. LAWSON, in reply to the criticism, said that in 1865 in a case of eczema which was regarded as epithelioma, treatment by zinc chloride was persisted in, until the tissue of the breast became deeply touched. Two years after, the patient returned with a bunch of diseased glands in the axilla and she is now dying of true cancer.

Dr. THIN—Explained that the epithelium at the mouths of the ducts may be affected, and the pathological change be confined thereto. If the parts be removed at this stage, the patient may be saved. But the destruction of tissue continues if only treatment for eczema be followed out; in time, the affection spreads along the ducts, and plunging into the body of the gland, irremediable mischief is set up, and a fatal termination ensues.

INTERNATIONAL MEDICAL ASSOCIATION, 1879
MEETING IN AMSTERDAM.

THE meeting which was recently held at Amsterdam of the new International Medical Congress, and which takes place every two years, has been one of the most successful reunions of the medical profession ever known. The illustrious professor Donders, of Utrecht, who acted as President of the Congress, was seconded in his unwearied efforts to make the Congress a success, by a host of learned and energetic brethren from among the professors of medicine of Amsterdam, Leyden, Groningen, and Utrecht. The committee of organisation also contained the names of Dr. Warlomont, of Brussels, Dr. Fabius, Dr. Stockvis, and Dr. Tilanus, of Amsterdam, and of the great oculist, Dr. Snellen, of Utrecht. Papers were read by Dr. Chauveau, of Lyons, Dr. Rosenstein, of Leyden, Dr. Stockvis, of Amsterdam, and a lecture was given by the learned German, Dr. Virchow, on "Ancient Troy." Dr. Bastings, of Brussells, Mrs. Hoggan, Dr. Schnitzler, of Vienna, Dr. Drysdale, Dr. Daremburg, of Mentone, Professor Semola, of Naples, and Dr. Delaunay, read papers in the Medical Section. Dr. Tilanus, of Amsterdam, read a paper on "Hernia," in the Surgical Section, and Professor Verneuil, of Paris, gave an admirable address on surgery in the general meeting which took place in the great hall in the Park. Mr. Sayres, of New York, gave demonstrations on his method of treating cur-

Digitized by Google

vature of the spine, at the hospital, and the members had the advantage of seeing the practice of calf vaccination carried out by the physicians of the general hospital. The Surgical Section was well supported, and papers were read by Dr. Küster, of Berlin, on the "Treatment of Aortic Aneurism;" by Dr. Bouqué, of Ghent, on the "Different Methods of Amputation;" by Dr. Magitot, of Paris, on "Cysts of the Jaws." The chief excitement, however, was caused by the address by Mr. Lister, on the Antiseptic Method of Dressing Wounds, delivered by him in the theatre of the Park. The meeting rose *en masse*, and gave the well-known surgeon many hearty cheers on his appearance. Mr. Lister read clearly and calmly in French.

In the Section of Midwifery papers were read by Dr. de la Faille on "Fibrous Tumours of the Uterus;" by Dr. Halbertsma, of Utrecht, on the "Prevention of Puerperal Fever," and one by Dr. van der Mey, of Amsterdam, on "Pilocarpine and Eserine as Contractors of the Fibres of the Uterus." Dr. Petithan, of Liège, read a very interesting communication to that section on the question, "The position that should be taken by Gynæcologists in those social questions which relate to Procreation." In face of the enormous infantile death-rate among the poor, and the consumption caused by overcrowding and too frequent child-bearing, Dr. Petithan recommended much smaller families than at present are in fashion, and said that he was well pleased with the views of Raciborski, which he had imparted to many of his patients, with the effect that they could thereby limit the number of their families. This communication was made at the instance of Mr. Donders, who wished that the question should be discussed.

In the Physiological Section, Professor Marey read a paper on "the Measure of the Pressure of the Blood in Man;" and gave a brilliant lecture in a hall called Felix Meritis, upon the "Circulation of the Blood." Dr. Engelmann, of Utrecht, read on "Muscular Contraction;" Dr. Heinsius, of Leyden, on "Sounds in the Vascular Spleen;" whilst Dr. Ranvier, of Paris, gave a microscopical demonstration, Dr. Javal lectured on the "Physiology of Reading;" and Dr. Onimus on the "Errors in the Theory of the Vaso-Motor Nerves."

One of the most attractive sections was that of Public Medicine, which was presided over by Dr. Overbeck de Meijer, and on the Council of which were Dr. Mouat, of London, Dr. Crocq and Dr. Janssens, of Brussels, Dr. Finkelberg, of Bonn, and Mr. Ernest Hart, of London.

The communication first in importance in this section was made in the general meeting in the great hall in the Park by Mr. S. van Houten, deputy for Groningen, one of the ablest Dutch statesmen of the day. He spoke on the protection of childhood against premature labour, and recommended all means to be taken to induce the poorer classes to relinquish the habit of giving birth to such hosts of unfortunate children as at present, who were only brought into life to die early, or linger on in poverty and degradation until carried off by consumption, by overwork, and privations.

Mr. S. van Houten received quite an ovation on commencing his address, which was in German.

Dr. Overbeck v. Meijer's paper on the "Methods of Preventing Contagious Diseases," was well discussed, as was also that by Dr. Seelheim, of Utrecht, on "Falsification in Food." Dr. Mouat spoke on this latter question.

Dr. Leeman, of Amsterdam, read a paper on "How the Public Health Ought to be Measured," which was also discussed.

Dr. H. A. Allbutt, of Leeds, read a paper on the mortality of children, in English, and Dr. C. R. Drysdale one on the "Comparative Death-Rate of the Rich and Poor." Dr. Drysdale also read a paper on the "Salicylate of Soda in Rheumatism;" and introduced the subject of the regulation of prostitution, at the general meeting in the great hall in the Park.

Discussions upon animal vaccination also took place in this section, and doubtless this custom will soon be adopted in England, since there is really no objection to it, and very many advantages, of which, perhaps, the greatest is that an unlimited supply of lymph can be obtained by its means in times of epidemics very quickly.

In the Sixth Section, that of mental diseases, a paper was read by Dr. van der Swalme, of Delft, on "Insanity as a Ground for Divorce;" and another by Dr. Lubansky, of Russia, on the "Influence of Alcohol in Causing Insanity."

In the Seventh Section Dr. Donders made a communication about the visual faculty of railway men; and Prof. Snellen spoke of the antiseptic method and its application to operations upon the eyes. Dr. Bouchut, of Paris, read a paper on "Retinal Hæmorrhage in Acute Cerebral Affections, and in Diathetic Diseases."

In the Section of Otology Dr. Guye, of Amsterdam, read a paper on "Menière's Disease," and Dr. Magnus, of Königsberg, on "Different Methods for Distinguishing the Acuteness of Hearing."

There was also a Section of Pharmacology, in which papers were read by Dr. Binnendijt on the "Poisonous Qualities of Phenic Acid;" and one by Professor Pacchiotti, of Turin, on "An Universal Pharmacopœia."

The exhibition of apparatus and materia medica was most interesting. Among other articles we noticed an excellent creasote soap made at the suggestion of Dr. Vacher, of Birkenhead, and a preparation of dried serum of the blood, also suggested by that gentleman.

The hospitality of the city of Amsterdam to its foreign visitors was very great. A visit to Imuiden, on the North Sea, took place on Wednesday through the great canal, and dinner was served on board. There were *fêtes*: one in the theatre of the Exhibition of Amsterdam, which still is employed as a concert room and playhouse; the other in a beautiful theatre near the Zoological Gardens, at which champagne and ices were plentifully distributed. Another *fête* took place in the gardens of the Park. In fact, it was clear that the people of Amsterdam know how to enjoy life. At the *fête* on Friday a charming tableaux, "The Lesson in Anatomy," was shown, when the professor and students were all beautiful young ladies. This was loudly applauded.

We append the contents of some of the papers read.

The Theory of Infectious Diseases, and of Vaccinia, was read by Professor Chauveau, of Lyons. The conclusions arrived at by the author are as follows:

1. The demonstration of the part played by the microbion ferments in the production of certain infectious diseases, of which charbon is the best known and most clearly proved type, may be extended to all diseases of the same order.

2. We are, then, authorised to consider infectious diseases as nearly related to parasitic diseases. It is even difficult to trace between these two orders of diseases a very clear line of demarcation. However, it has been proposed to lay down that in the first class the parasitic agent acts exclusively by the mechanical obstacles, irritations, and destructions of local character caused by its presence and development. In the others this mode of action has only a secondary influence; the parasitic agent produces above all its evil effects by altering the humours, and in thus disturbing, by the play of its proper life, the physiological life of the anatomical elements.

3. The parasitic microbions, the agents of infectious diseases, behave within the organism similarly to fermentative agents as injurious by the products with which they infect the economy, as by the subtraction of useful substances which they remove from the humours and tissues.

4. To each specific infectious disease there belongs necessarily a special agent. But it is not proved that the microbions which cause the infection all constitute distinct species rather than different forms of a small number of species. The opinion expressed about the point implies simply the identity of characters and properties of the infectious agent in all cases of the same disease. Besides, there is reason to believe that all the infectious microbions belong to one and the same family, that of septic ferments. All the true diseases which are infectious, such as charbon, surgical septicæmia, pyæmia, and traumatic gangrene, the different kinds of typhus, &c., are, in truth, septic or septicoid diseases.

6. If the infectious microbions are septic ferments, they ought to have the power of living and multiplying out of the animal economy. Experience shows, indeed, that all those which are known possess this common and fundamental character. Thus the germs are disseminated in a permanent way, it may be said, in the external world.

7. In certain infectious diseases (example, marsh fever) the infected person always derives the germs from the external world, never from other persons already infected. The latter appears to be unfit to give back these germs to the external world, and to serve as agents of contagion.

8. Other infectious diseases (*e.g.*, ileo-cæcal typhus) behave differently. The patients, foci of production of germs, which after having been given forth to the external world, infect the injesta, may thus become indirect and limited foci of contagion.

9. Lastly, there are some infectious diseases (exanthematic typhus) where the germs given forth by the patients infect

Digitized by Google

not only the *injesta*, but also the *circumfusa*. The subjects infected thus become extremely active centres of direct contagion.

10. Should the so-called virulent diseases, of which vaccinia is the type, the simplest and best studied of all, form a distinct category of infectious diseases? Experiment has shown, it is true, even before the demonstration was rigorously made for infectious diseases, that the virulence is found in the solid particles of the humours. But nothing proves that these particles are microbions, like those of infectious diseases. We do not, indeed, arrive at being able to cultivate the proper viruses outside of the living organism, and the manner in which they behave in the presence of certain poisonous agents is incompatible with the attributions of the quality of living elements. Still, we must make all kinds of reserves about the radical distinction between infectious and virulent agents. Besides, the limit between the two orders of diseases is very hard to be laid down at present. The progress of observation and experiment will perhaps efface this, and establish the identity of nature of all contagious diseases, which would then, without exception, become parasitic.

Professor Rosenstein, of Leyden, read a paper on "Bright's Disease and Primary Cirrhosis of the Kidneys." His conclusions were as follows :—

1. The anatomical lesions of the kidneys, which make up the *ensemble* of the clinical symptoms described first of all by Bright, always relate as well to the parenchyma as to the connective tissue of the organs.

2. There is no such thing as nephritis, exclusively parenchymatous, or exclusively interstitial. We may affirm, basing our views on experience and clinical observation, that whenever a true inflammation of diffuse kind exists in the kidneys, the two histological elements are affected from the outset.

3. The final product of the diffuse inflammation is the white kidney, and the red granular kidney. They form, in an anatomical point of view, the atrophied kidney, and only differ in this way, that the parenchymatous affection is more marked in the first, whilst the interstitial is more so in the last named. In a clinical point of view, we may distinguish one from the other by the analysis of the urine. The symptoms of atrophy are common to both.

4. Clinical observation makes the opinion probable that the red granular kidney as well as the white, or as it is called, the primary cirrhosis of the organ, is preceded by a period of tumefaction. Post-mortem examinations do not contradict this way of looking on it.

5. The clinical description of Bright relates especially to the white granular kidney. It is certain that in this modification the morbid process runs through two stages, as well in the clinical point of view, as in the anatomo-pathological one.

Papers were read also, in the First Section, by Mrs. Hoggan, M.D., on the "Relation of Carcinoma with the Lymphatic System." Dr. Decrosa, of Paris, President of the Society against the abuse of tobacco, read a paper on the "Influence of Tobacco for or against Scurvy." Dr. Schnitzler wrote on "Syphilitic Lung Affections;" and Dr. C. R. Drysdale, on "Salicylate of Soda in Acute Rheumatism." Professor Semmola, of Naples, had a number of papers, viz., on "Interstitial Hepatitis," on "Nervous Dyspepsia," on the "Treatment of Lead Colic by Continuous Current," on "Addison's Disease," and on the "Treatment of Hydatids of the Liver." Professor Zawerthal, of Rome, read a paper on "Laryngeal Syphilis," and Dr. Delaunay, of Paris, on the "Treatment of Phthisis."

The next meeting of the Congress is fixed for London in the year 1881. There will, however, be a meeting of the Congrès International d'Hygiène in Turin, in August 1880, so that it may be said that the medical men of Europe have now an annual international parliament.

Department of Lunacy.

THE COMMISSIONERS IN LUNACY ON THE LUNACY LAWS.

The Commissioners in their Report, to which we have previously alluded, make some valuable remarks on the recent Parliamentary Committee, and express their own views on the important question of lunacy legislation. We propose to briefly give our readers a short *résumé* of these views of the Commissioners in Lunacy. The suggestions of the Committee as to the consolidation of the Lunacy Acts meets with the approval of the Board. We think that this would be a step in the right direction, and prevent a great deal of confusion that at present exists in consequence of the number of acts of Parliament relating to lunacy that we now have. There are four principal lunacy acts, besides a number of smaller ones, and as many of the sections in the older acts have been repealed in the recent ones, it would be a great advantage to amalgamate these for easy reference, so as to prevent mistakes. The Commissioners state that they are not prepared to suggest any radical change in the existing lunacy law, they say, "we are quite satisfied that the present system of certification, both of private and pauper lunatics, and of visitation of the asylums, hospitals, licensed and unlicensed houses, where they are received, affords in practice ample safeguards, as well against the admission of persons of sound mind, as for the discharge of the insane patients under detention."

This is, indeed, satisfactory to those medical men who devote their lives to the care and treatment of the insane, but who have been so unjustly attacked by som ignorant persons.

With regard to granting of the present "medical certificates" for admission into an asylum, they are considered to be susceptible of improvement by the Commissioners. The name and address of the person furnishing the facts indicative of insanity in the certificates ought to be legally enforced. This is required by the Commissioners, though there is no compulsory enactment to this effect. It is suggested by the "Board" that the "Order" for admission should be called an "Authority," or "Request for Reception."

With reference to the signing of this "Order," the Commissioners think that, if no immediate relative can be found to sign and undertake the responsibility of placing the case under restraint, that it should be distinctly so stated in the "Order" no relative was available. It is suggested, and very properly too, that power should be given to the Board to substitute for this "emergency" signature, a near relative at the discretion of the Commissioners, but who at the same time is prepared to, and has consented to, act in the matter. It appears that this was one of the recommendations made by the Lunacy Committee. It is considered advisable that the person who has signed the "Order for admission" should undertake the visitation of the lunatic at stated periods, but of course, this must be left to the discretion and judgment of the medical officer of the asylum. As a means to enforce this it is suggested that there should be subjoined to the "Order for admission" an undertaking by the person who signed, to visit personally, or by deputy, the patient every six months.

The following is the proposed "Order" and consent to visit :—

"I, the undersigned, being a person aged 21 years and upwards, hereby authorise you to receive A. B., a lunatic [1], whom I last saw at on the [2] day of 18 , as a patient into your house [3]. Sub-

Digitized by Google

joined is a statement of particulars relating to the said A. B., whom I undertake to visit personally, or by some one specially appointed by me, once at least in every six months while under care and treatment under this authority."

Here follows the name, profession, and degree of relationship.

[1] Or an idiot, or a person of unsound mind.
[2] Some day within a calendar month from the date of authority.

(To be continued.)

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, OCTOBER 29, 1879.

SALUS IN NUBIBUS.

DR. RICHARDSON'S Croydon Address must be considered in the light of an addendum to the oration he delivered before the Social Science Association at Brighton in 1875, and naturally the judgment to be passed on it will be materially influenced by the impression remaining from the earlier teachings of this apostle of longevity. In common with all enthusiastic theorists, Dr. Richardson exhibits a too willing readiness to adapt the premises of his arguments to the conclusions he is anxious to deduce from them. Rather than accept without demur the inevitable consequences attendant on continual progress, and apply these as agents in the development of his picture of a perfect life, Dr. Richardson prefers, after the manner of the unpractical speculator, to build up new beings to people his Utopia; beings with feelings, with ideas, with aspirations, with desires, as unreal and as unlike the feelings, ideas, aspirations, and desires of the nineteenth century mortals as it is possible to conceive.

We are far from denying Dr. Richardson the proud distinction that must unhesitatingly be assigned to him, that, viz., of being the foremost, if not the most practical of sanitary reformers. It may be that the attractive discourses which appeal to the imagination, we might at most say to the fancy, rather than to the practical common-sense appreciation of an audience, are calculated to effect a good as great and as lasting as that produced on the mind by unadorned arrays of actual facts, supplemented by inferences drawn from them. But we confess to a dubious uncertainty whether the ultimate outcome of the one mode of exposition is likely to be as productive of great changes as that which will follow from the adoption of the other plan. In the admiration momentarily excited by the ringing utterances of an eloquent and excited orator, burning with eagerness bred of his own impetuosity, earnestly endeavouring to make converts of all to whom he can extend the influence of his speech and manner, we are unconsciously driven to accept expressions and opinions, a further calm survey of the matter and consequence of them must infallibly shatter.

In this way do we regard the speeches of Dr. Richardson. His earnestness, his single-heartedness, even the extremeness of his views, cannot but command the respect of every one who is familiar with the man, or his work. But this does not mean that, therefore, to the suggestions and the pictures shadowed out in forcible and glowing colours, will be similarly accorded the full meed of implicit trust. Herein reason steps, and reason emphatically declares that it is impossible to look on the realisation of the hopes expressed in "Salutland" as aught more than the fanciful sketch of a too vivid imagination.

In determining the conditions to be regnant in the sanitary paradise; in allotting the actions and motives that are to be the attendants on, and incentives to, the continuous advancement of a hygienic *régime*, a *régime* to be eventually exact in accordance with every natural physiological law, the inventor of Salutland departs from the realms of the possible and probable, to dream blissful visions of an impracticable and utterly impossible kind. The life he sketches forth can be lived by no men and women who will inherit the social tendencies of the existing generation; and more than this, the realisation of the scheme presented in Dr. Richardson's address can succeed only to the denial by a community, and subsequent rejection, of one of the most potent laws by which the social organism is controlled. The community grows in the same fashion, and after the same ruling as that on which individual development is dependent. Through the reaction of the environment on the individual is the latter moulded; and until the whole course of human passions and human cravings is entirely changed, not even the first step in the direction of the revolution indicated can be taken. It is not sufficient to say the indications of radical metamorphosis in the customs and aims of society are apparent, and that, under due encouragement, the ultimate goal to which they are directed is the mode of existence depicted by the President of the Sanitary Congress. We have not the proof of this; we have only so much to favour the impression, sought to be conveyed in the recent address, as is contained in the evidence of a growing wish among the masses to be relieved from something at least of the incubus of dirt and the disease

Digitized by Google

dependent on it; but by no stretch of a sanguine imagination is it possible to convert this into a desire on the part of the world, or a nation of it, to enter on the tedious course of life we are called on to inaugurate. The spirit of the age is the spirit of progress, truly; and in such measure as the progress made can bring enlightenment to the people, can expose the dangers incident to disobedience of natural and sanitary laws, and can open our eyes to the importance of rigidly adhering to a system of conduct the best calculated under circumstances to favour healthy living—changing perhaps as circumstances change—but always following the indications of social and instinctive necessities, so far we venture to predict the spirit of this and succeeding ages will be a spirit of productive benefit. But the transaction from this position, to the vain and illusory assumption that a period of years, numbered within the space of the Salutlander's existence, will suffice to bring about changes involving complete remodelling of every social factor, is too abrupt, too distinctly careless, to admit of possibility under the conditions that now attend all human thought and hope.

We do not propose to discuss the separate heads of Dr. Richardson's address. We could not conformably with its deserts treat it in the space at our disposal. We seek rather to demonstate the untenable nature of his imaginings; to show that they can claim only such attention as should, and will, we trust, be always accorded to the eloquent utterances of able and earnest men. But the earnestness and ability of Dr. Richardson do but serve to intensify our regret that he should choose to appeal to his hearers by placing visionary schemes of an impossible life before them, rather than employ his brilliant powers of exposition to demonstrate the errors that beset the path the world is treading. We cannot suppose that injunctions to immediate reform, and assiduous endeavour in the direction of proper hygiene, would be conveyed with any less force, or with any decreased influence, because uttered in the plain language of unadoned common sense. Such a supposition would carry with it condemnation of a fault to which the English public, at its worst, is never prone. It is at all times ready, and can be made anxious, to learn the difference between right and wrong conduct in regard to its own welfare; and if, instead of treating us to a demonstration of "health in the clouds," Dr. Richardson had chosen to expose the chief of the sanitary mistakes constantly made in our midst, and indicated means for their avoidance, simple means, open to all to employ, we should have been better able to give a hearty welcome to his oration.

THE ADMININISTRATION OF THE PUBLIC HEALTH ACT IN IRELAND.

In justice to the medical sanitary officers of Ireland we found it necessary last week to repudiate, on their part, all responsibility for the break-down of the Public Health Act in Ireland, and to show, upon the evidence of Parliamentary papers, that those officers actually performed the duty confided to them with zeal and efficiency, until they were compelled to give way before the opposition of the sanitary authorities and the discouragement by the Irish Local Government Board. Having done justice in that respect to the medical officers of health we hoped that it would not be necessary so soon to revert to the subject of Irish sanitation and the proceedings of the Irish Local Government Board, and we regret that the latest act of that department since we last wrote obliges us to re-open the matter. Within the last week the Board has promulgated an order to certain boards of guardians, which order we believe to be not only inexpedient in the public interest, and most unjust to medical officers of health, but absolutely illegal and a gross breach of faith towards the Irish Medical Association which represents these officers.

Our recent articles have, no doubt, reminded our readers that when the Public Health Act of 1874, became law the Irish Local Government Board availed itself of the terms of the 11th section to forbid sanitary authorities to grant adequate salaries to their sanitary officers. That section was as follows:—"Provided, with regard to salaries or additional salaries, whereof any portion is to be recouped to any local fund from moneys voted by Parliament, the amount of any new salary, and the proportion between any existing salary and the addition thereto, shall be regulated *according to a scale* to be approved by the Commissioners of Her Majesty's Treasury." The force of this clause was, that the Treasury should have power to limit, by a general scale applicable to all cases, the salaries payable to sanitary officers. Either under the advice of the Local Government Board, or *proprio motu*, the Treasury did impose such a limit, and thenceforth all sanitary authorities were ordered to pay no more than one-fourth of the dispensary salary in each case, and in a few instances in which the guardians had already voted a larger sum, they were compelled to fall back to the limit.

The Irish Medical Association had never anticipated that the Irish Local Government Board would make use in this way of the powers given by the Act, and they protested publicly and officially against so foolish and unjust a proceeding. They pointed out that—in any case—one-fourth of £100 a-year, was a preposterous under-estimate of the remuneration proper for an efficient discharge of duty, and that, even if such a sum were adequate, it was a ridiculous system to assess the services of all sanitary officers at the same value, no matter whether the district over which their duty extends was large or small—overpopulous or sparsely inhabited—squalid or aristocratic, fœtid or clean. As our readers are aware—neither argument nor remonstrance had, in those days, much effect upon the Irish Local Government Board and its notable vice-president, and, therefore, they will understand that the protests of the Irish Medical Association produced no effect. But the time came for action. The Public Health Bill of 1878 was introduced, and was found to contain words which we have quoted above. The Association waited by deputation on Sir Michael Hicks-Beach at Westminster, and urged upon him the propriety of withdrawing the limit imposed by this "scale," and leaving the amount of salary to the unrestrained discretion of the sanitary authorities. Again, the Association was represented for the same purpose by Dr. Grimshaw, when the Bill was before the Select Committee, and subsequently,

Digitized by Google

the point was pressed upon the Government with all the vehemence possible by Mr. Meldon, M.P., acting for the Association. The result of these representations was that —the Bill being *in extremis*—the Government consented to the request and undertook to withdraw the "scale," and in the Act as it now stands the word is omitted, and it is explicitly stated that, "the amount of any new salary shall be approved by the Treasury." The object which the Irish Medical Association had in view in urging the change was to insure that each particular case should be decided on its own merits, and the remuneration of the officer decided upon by the Guardians on consideration of the nature and extent of his sanitary duties; that the Local Government Board should sanction the individual assessment if they considered it reasonable, and should then send the whole of the salaries so sanctioned to the Treasury for final approval.

It will be difficult for our readers to believe that—in spite of this change in the terms of the Act, and the explicit understanding acquiesced in by the members of the Government who had charge of the Bill—the Irish Local Government Board now seeks to enforce the "scale" as it existed in the former Act, and has refused its sanction to salaries in excess of that scale, voted by the Rathdown Guardians, and the Blackrock and Kingstown urban authorities, on the ground that they were not authorised to sanction a payment of more than one-fourth of the dispensary salaries. When the Council of the Irish Medical Association received the first information of the intention of the Local Government Board to cause new salaries of sanitary officers to be passed, they at once addressed the Board officials in the letters which we publish in our Irish Supplement of to-day, and of which we give a few excerpts here. The Council of the Irish Medical Association reminds the Local Government Board that, for some little time after the passing of the Public Health Act of 1874, considerable zeal was manifested by many of the medical sanitary officers, and there can be no doubt that that energy was exercised in expectation that their services would soon be appreciated, and that the salaries appointed—which, as a rule, were utterly disproportionate to the nature and extent of the duties—would thereupon be increased.

However, the medical officers soon found that the scale fixed, as directed by that Act, precluded the possibility of equitable remuneration being allowed for efficient services, and that their interests as medical practitioners were very seriously and prejudicially affected by the faithful discharge of their duties; and in consequence of the evident discouragement shown by the sanitary authorities to anything like efficient service, the result was a marked falling off in the efforts of the medical officers which, eventually, greatly diminished.

In consequence of the small amount of work recently performed by the medical officers, the Council fear the local sanitary authorities may avail themselves of this as a pretext for either not proposing an increase in the amount of the former salary, or even possibly of suggesting that it should be diminished, though it is inconceivable that they could fall into the error of supposing that the amount of work which due regard to the public health requires to be done is insignificant.

The Council confidently expect that the Local Government Board will not confirm the allotment of any salary to a medical officer of health which is not equitable remuneration for efficient service.

The Association, furthermore, remarks that unless, and until, reasonable and equitable remuneration is allowed to the medical officers of health, it is futile to imagine that the provisions of the Public Health Act can come into effectual operation; and further, that the past work done by those officers cannot be considered to indicate the amount of remuneration that should now be allowed; but that, on the contrary, the amount of the salary will, to a great extent, regulate not only the manner in which the duties will be performed, but also the extent of them which will be voluntarily undertaken; and, in the absence of any provision for supervision, this appears to be a very important consideration.

To this very reasonable representation the Irish Local Government Board would seem to have given no heed whatever, and—as we have said—their next step was to refuse to sanction fairly sufficient salaries voted by the Blackrock and Rathdown sanitary authorities. The moment the Irish Medical Association learned from the reply of the Board to the foregoing letter, that the re-imposition of the abrogated "scale" was contemplated, they at once entered their protest by a further official communication to the Board.

In this letter the Council "respectfully dissent from such reading of the 11th section of the Act; and express their decided opinion that the Public Health Act of 1878 does not empower the Treasury or any other authority to fix a *general scale* or ratio of remuneration, or to impose any maximal limit whatever upon the discretion of the sanitary authorities, save that which the Local Government Board are authorised to impose when called upon to sanction the proposed salary of each individual officer, whose case shall be separately considered. The Council still most strongly feel, that the fixing of a limit of salary, which could not be exceeded, was tantamount to an intimation to the sanitary authorities of Ireland that the services of the medical officers were not to be requited in proportion to their extent and their nature; and, further, that as there is no relation whatever between the sanitary work and the dispensary medical work of any given district, the dependence of the amount of the salary of the medical officer of health upon that of his salary as dispensary medical officer is, therefore, neither just nor expedient. The Council conceive that the application of any fixed general scale or ratio in the estimation of such salaries would be at variance to the wording and intention of the Act, as well as a direct violation of the assurance of the official representatives of the Irish Executive that each case would be separately dealt with according to its merits."

We again challenge this act of the Local Government Board as totally illegal and contrary to the terms of the Act of Parliament, and—if it were not so—we protest against it as a discreditable infraction of the pledges given by the Irish Government. As to its illegality, we are corroborated in our view by the opinion given by Mr. Purcell, Q.C., on this very point. He says:—

"I am of opinion (in accordance with my view of the

Digitized by Google

construction of the Act of 1878) that all arrangements made by the several sanitary authorities as to the additional salary to be paid to their respective dispensary medical officers, under the 10th section of the Act of 1874, were determined by the repeal of that Act, and that the several sanitary authorities are now bound to appoint the additional salary to be paid to their respective medical officers of health, under the 11th section of the Act of 1878, subject to the approval of the Local Government Board; *and that in determining the amount of such salary, neither the sanitary nor the Local Government Board should have regard to any fixed or particular scale of remuneration, but only to the extent and nature of the work to be performed by the medical officer of health in each particular case.*"

With our previous experience of the legal decisions upon which the Irish Local Government Board have acted, we prefer Mr. Purcell's verdict to that of the legal adviser of the Board.

It certainly seems to us that this is a matter calling for peremptory action on the part of the Irish Medical Association. We may assume that earnest remonstrances will be made at once to those members of Government who pledged themselves to the abrogation of the "scale"; but, if this should not suffice, we think that the legality of the proceedings should be submitted for the verdict of the Court of Queen's Bench.

RESIDENCE ABROAD IN LUNG CONSOLIDATION.—I.

At this time when invalids and swallows are both migrating southwards, it may be well to consider the pathological conditions for which more southern climes are advised. By southern climes we do not here confine ourselves to areas of higher winter temperature than our own, but include areas with a lower temperature, though of greater dryness. It is the moisture of our winters which render them so objectionable to many cases of disease of the lungs. To avoid this damp atmosphere patients have been sent abroad to drier, warmer climates. Then it was found that many patients lost more than they gained by the effects of the higher temperature. What amount of improvement or benefit had accrued to the lungs was more than counter-balanced by the general loss of tone, which resulted from the effects of the winter warmth. Then several such patients found that a high-lying, bracing area suited them much better, on the whole, than the warm climate, the air in each being equally dry. Then came the fashionable resort to the high-lying valleys of Switzerland and the Tyrol. The Engadine became the most fashionable—for no other adjective can correctly be applied—resort, and now Davos Platz is the last new novelty. San Moritz was first described as being free from tuberculosis amongst its aboriginal inhabitants. Then we heard of a "supra-tubercular zone," of areas of such an altitude that tubercle could not make the ascent. Several observers independently had noted the fact that the percentage of deaths from phthisis fell the higher the altitude. The logical conclusion from this was attractively simple, viz., that if we could get high enough phthisis would clearly be left behind. And so it is now the prevailing belief that a high Swiss or Tyrolese valley is the enchanted ground where tubercle may not show its face. No doubt there is much to be said for these places, just as there is much to be said for the shores of the Mediterranean or Upper Egypt, and used to be said for Madeira, the Azores, and the Cape. But so long as fashion determines the locality in which the consumptive must reside, reason must be satisfied to be permitted to stand in the background. Probably there is no harder question to solve in many cases of phthisis than that of where shall the patient go to abroad; for of course it must be abroad now. England is no place for the phthisical—that is quite certain. If the patients' means will not allow of their leaving their foggy, tubercle-stricken fatherland, then they must reconcile themselves to an early death. Yet somehow or other an experience at a large chest hospital convinces us that recovery from apex consolidation is the rule for those who have not a bad family history. We will readily grant certain advantages in winter health resorts abroad. First, they certainly have more sunlight; about that there can be no question. Second, there is a less humid atmosphere, even in Madeira. Third, the air is free from mechanical irritants; a matter which does not receive the attention it merits. Fourth, the rapid and severe oscillations of temperature to which this country is so liable, are avoided. Fifth, if the day variations of temperature out of doors is great, still it is regular; and there are several hours when the patient can get out in the invigorating sunlight. Sixth, in high altitudes the air is still; in more strictly southern climates, if not so still, there are not the gales to which we are so subject at home. Seventh, the greatest care is taken to secure every hygienic arrangement, instead of the invalid having to accommodate himself, or herself to family arrangements. Here are some very valid reasons, then, for sending invalids with lung mischief abroad; especially if intelligent thought be applied to the requirements of the case, and a critical judgment arrived at as to whether it should be Davos, Torquay, Nice, or an Australian voyage. But is such care usually given? We doubt it very strongly. How many men are capable of taking first, and weighing afterwards, the evidence in each case? How much easier is it to rap out the name of the latest fashionable resort, than to justly and painstakingly weigh and appraise the value of each factor in every case. We do not say that such care is not given; but we do confidently assert that there is something suggestive about the proportion of patients which some physicians find it necessary to send abroad, as compared to the practice of others. The physicians who insist so very strongly on the "going-abroad treatment" of lung disease, constitute what the Americans term a "ring." To indicate who constitute this ring would be easy; but invidious.

Having said so much about foreign health resorts, let us look a little attentively at the pathological condition for which patients are mainly ordered abroad. A person, usually a young person, is not very well, or for some insurance reason, or some caprice on the part of some relative or friend, consults a medical man; who, upon physical examination, finds one or other apex consolidated. Immediately thereupon alarm and consternation seize upon all. Hitherto, the patient—for from the moment of discovery he, or she, must be so regarded—

Digitized by Google

has been living indifferent to hygienic surroundings, or even in defiance of them. A girl may have been living in a very damp, low-lying place, amidst any amount of moisture, and with a low barometric pressure, as a rule; in a dark house, surrounded by trees, and on a strong clay soil; in fact, every unfavourable factor secured, as if by malice; but when it is found that she has a consolidated apex she is sent away to Davos. Here she improves. No one can dispute that. Her parents have unquestionably got something for the expenditure, which is no trifle. But surely it is permissible to ask how much of this is due to the fact of leaving unfavourable surroundings; and how much, or perhaps how little, to any peculiarity in Davos? Placed on a bracing southern down, or amongst the heathery hills of Wharfedale, probably an equal amount of improvement would have followed. Even if an absolutely equal amount of good is not quite attained; does Davos give a just equivalent of benefit for the expense, the exile, the danger and discomfort which overhang acute illness in a foreign land Every medical man ought to have an experience, a personal experience, of acute illness and confinement to bed in a foreign land; and then he would be in a fitter position than he ordinarily is, to weigh the factors of each case, and calculate possibilities as well as probabilities. If the patient is going to be absolutely free from intercurrent illness; if the appetite is to remain good, and the digestion equal to a foreign dietary; if the patient can get out pretty constantly; then the answer simply turns upon the matter of pecuniary means. These remarks apply equally to a residence abroad, and a sea voyage; unfortunately, they strike and cut both ways.

THE DUBLIN SANITARY COMMISSION

Has closed its labours and, though its inquiries have not been nearly as exhaustive and complete as they might have been, considering how long we have waited and how important are the issues, nevertheless we feel justified in warmly congratulating the citizens of Dublin upon the result of the investigation. It is to the good sense and zeal of the Commissioners themselves that we owe this, for certainly the Chief Secretary had done what in him lay to tie their hands and discourage thorough exposure of the sanitary defects of the city, and the Corporation would have been well pleased if the Commissioners had confined themselves to the question of Liffey purification, and had kept clear of the wholesome exposure of Dublin filthiness and civic incompetence, for which we have to thank them.

It may not be to much to hope that, if the citizens do not rest from agitation, this inquiry may yield subtantial benefits to Dublin. At all events, it will no longer be possible for the Public Health Committee to poohpooh! the outcry of the citizens, and we are gratified to observe that that committee has been wise enough to effect a complete change of front in its policy. Twelve months ago they could not be brought, by any means, to see that the sanitation of Dublin was not perfect. According to their account the excess in the death-rate was all imaginary, and the apparent mortality was only the exceptional result of the weather and of erroneous registration —the city was as clean and neat as its position in a "mud valley" would allow it to be—the habitations of the poor were quite good enough for such people, and, if they *were* somewhat dirty, that was the inevitable effect of the poverty and intemperance of the artisans. On the whole, in their opinion, it was as safe (and much less troublesome) to "let well alone," and the complaints of the Sanitary Association and of the *Medical Press* were nothing but the splenetic snarling of fussy and self-interested agitators.

What a miracle has the Commission worked!!

Like Baalam, the prophet, the Corporation witnesses came to curse, but stayed to bless, and with one voice they proclaimed the state of the city to be simply indescribable. The scavenging of the city—they allowed—was utterly bad and insufficient, but—they said—was as good as they could afford; the house sewerage was—they admitted—radically defective; the habitations of the poor—they confessed—baffled description of their filthiness; the Liffey—they asserted—was a poison to the city, and the recorded mortality was too true. For such a conversion the Commission cannot be sufficiently thanked, and we can only cherish the hope that the change of opinion is one of honest conviction which will bear good fruit.

In truth, the exposure of the insanitation of Dublin has been complete. Not one witness—engineer, doctor, official, or corporator—was found to dispute the facts, or mitigate their gravity, and we believe ourselves justified in epitomising the evidence by saying that it was unanimously agreed that, neither the Liffey nor the Vartry water had much to say to the unhealthiness of the city, but that that condition was the outcome, principally, of rank, inexcusable filthiness—filthiness in the drainage of the houses of the rich—filthiness spread out on the surface of every street in Dublin—filthiness sweltering in the hovels which, in this city alone, do duty as the habitations of the poor. We need not pursue the subject further. Let the Public Health Committee profit by the lesson they have learned, and, put for ever behind them the policy of seeking out excuses for inaction in lieu of activity and zeal. They have now in hand the powers newly granted to them by the Public Health Act. They have facilities for getting what money they require; they have the line of action pointed out to them by a Royal Commission, and they have the feeling of the citizens strongly with them. We earnestly trust that they will set honestly to work and endeavour to solve the problem.

Notes on Current Topics.

Quack Medicines.

Magna Charta has settled the glorious privileges of Englishmen: the liberty of the subject would be infringed if restrictions were imposed preventing him from poisoning himself or his infants, or preventing the patent-medicine vendor from selling to him patent medicines for the purpose. There are many ways of killing. Direct murder is one thing, indirect another, so we must distinguish. The latter we have to deal with. You commit

Digitized by Google

indirect murder by mistaking your diagnosis, and giving for the disease something which cannot do any good, or which may partially do harm. How many instances are there of this in connection with children and their diseases, and druggists prescribing. Bronchitis treated for, when really the child is suffering from incipient hydrocephalus; albuminuria overlooked, and the child dosed with spirits of nitre to make the kidneys work—and then? Why the nearest churchyard. Patent medicines, containing poisonous ingredients, have much to answer for, and the sale of such quack medicines, we regret to say, is not sufficiently controlled.

Governments take a more philosophic view of the subject. The over-increase of the population is marked; this leads to pauperism and crime, causes a higher poor-rate and other expenses, with police, gaols and convict ships.

Checks on population have been much talked of. There is no better check, than quack medicines of the soothing syrup type.

Fucus-Vesiculosus (Anti-Fat).

Now that this remedy is so universally used for the reduction of obesity, it may interest the profession to recall to mind another use found for it in 1826.

Laennec having observed that on the coast of Brittany, where the air is more humid, but at the same time milder and more equable than in the interior of France, the number of phthisical patients was comparatively small, and having also seen that young men from Brittany became consumptive during their sojourn in large cities, and recovered on returning to their native province, came to the conclusion, that the peculiar atmosphere of the sea coast had something to do in these results.

He, therefore, tried to imitate it, in some measure, by placing near the beds of the patients certain fresh marine plants. He brought together, into two small wards, a number of phthisical patients, and surrounded their beds with the *fucus vesiculosus*, causing them to drink also an infusion of the same plant. None appeared to suffer from this mode of treatment, as long as the fresh *fucus* could be procured.

The cough became less frequent, the breathing less confined, the expectoration less in quantity. In the greater number the hectic fever ceased, and *the progress of emaciation was arrested.*

In 1826 the *fucus* caused fattening and arrest of emaciation; now it produces emaciation, or rather it reduces bulk, according to testimony of many writers, who perhaps do not take into account the diet they adopt, or the hygiene they follow, as being a more important factor in the matter.

We do not hear now of *fucus* in consumption. In fifty-three years' time shall we hear of Anti-Fat?

The Electric Lighting of the British Museum.

During the past week a more successful attempt than that of last winter has been made to prevent the locking-up of the literary treasures of the British Museum at dusk. It will be remembered that for a brief period at the commencement of the present year, Mr. Bond, the indefatigable chief librarian, being anxious to give increased facilities to readers, and extend the hours of reading during the dreariest months of a London winter, persuaded the trustees to let him introduce the electric light into the reading room. To bring gas into the building was out of the question. Its deteriorating action upon the surroundings of the place, its destructive effects upon the bindings of books, and above all the danger of a possible explosion, or a fire at some unguarded moment, were more than sufficiently good reasons for determining the point. Therefore, without the electric light the half-million of books must for ever have remained sealed up during the best part of the reading months of the year.

The present system of electrical lighting differs materially from that before tried. It will be remembered that a number of standard lamps about eight or ten feet high surmounted the several reading compartments. This threw too deep a shadow over the more distantly situated desks, and presented other defects. On this occasion the scientific improvements effected by Siemens, both in the magneto-electrical machine and the candle have been called into requisition. Now, four lanterns, each of 5,000 candle power, are suspended from the dome at regular intervals; and these are found to shed a soft and tolerably uniform white light over the whole area. Those readers situated at the furthest part of the room found the light sufficient for all the purposes of reading and writing in comfort. The various colours of the reference volumes around the walls are perfectly distinguishable, and their titles can be easily read. The effect of the light upon the eye, so far as we have been able to ascertain, after continuous reading, is far less fatiguing to the eye than that of ordinary lamp-light, which from certain well-understood defects, are for the most part rather injurious than otherwise. In pure solar light the blue ray is present in almost equal quantity to that of the red and green together; when this proportion is materially altered, as it is in artificial modes of illumination, then the light, whatever its source, is liable to induce fatigue and injury to the organ of vision. The blue ray also affords by far the best definition of objects, and since this preponderates in the electric light it will be at once understood to be less fatiguing and hurtful to work by than that of gas or oil (or for the matter of that, of our London fog), in both of which there is a preponderance of the red or yellow, or green rays. Owing to some faulty construction of the carbons in use, at times the light flickers and diminishes for a few seconds in intensity, and we notice a preponderance of the red over the blue rays. This is a slight drawback, although of little account, and will doubtless be soon overcome. Those, however, who are exposed to the full glare of the light, will not fail to notice this, and may have some fear of injury to the sight. Meanwhile they will find great comfort in the use of pale cobalt blue spectacles, which tone down the light and render it uniformly comfortable and agreeable. We observe that the lights placed in front of the building and in the entrance hall, which are supplied with an interrupted current of electricity are more perfectly steady and give a more uniform light than those in the library. The cost is somewhat more, but this, after all, is a matter of very little moment, as those in the reading-room can, we are told, be produced for the trifling sum of one shil-

Digitized by Google

ling each per hour. On emerging from the reading room the gaslights in the streets look duller and dirtier than ever.

New Fellows of the Irish College of Physicians.

At the recent elections which took place on St. Luke's Day the provisions of the new supplemental charter took effect, and, under it, the elections were held by ballot. For a very long time, up to a few years ago, the Fellows of the College had always been elected in this way, but the validity of the method was challenged, and a legal decision obtained under the old charter—the election must be by open vote. The college has taken the opportunity of its new charter to revert to its former system, and thus the choice of Fellows was made last week.

The following gentlemen were elected :— Reuben Joshua Harvey, M.D. Dub. 1873, L.K. & Q.C.P.I. 1876, Lecturer on Histology and Physiology in the Carmichael College ; John Rutherford Kirkpatrick, M.B. Dub. 1855, L.K. & Q.C.P.I. 1859, a Fellow and Examiner in Midwifery of the Irish College of Surgeons ; and Francis John Boxwell Quinlan, M.D. Dub. 1862, L.K. & Q.C.P.I. 1859, one of the medical staff of St. Vincent's Hospital, and a Professor in the Catholic University.

Dr. Kirkpatrick is obliged by regulation to resign his fellowship of the College of Surgeons, and, of course, his examinership.

Clinical Society of London.

At the second meeting of this Society held on Friday last, an important discussion took place, in which Sir James Paget, Mr. Jonathan Hutchinson, and others, engaged. We draw the attention of our readers to the report of the proceedings to be found in another column.

The New Membership of the Irish College of Physicians.

We publish to-day in our advertising columns an amended abstract of the regulations, which we gave *in extenso* in our last issue. The following amended regulation are of special interest to the licentiates of the college :—

All persons who have been admitted licentiates of the College before December 12th, 1878, shall be entitled to be admitted members of the College without payment or examination on giving six weeks' notice, in writing to the registrar, of their intention to avail themselves of the privilege conferred by the supplemental charter, and on complying with all or any other prescribed conditions, provided that they have, since their admission as licentiates, obeyed the bye-laws of the College.

Every candidate for the membership of the College must be a licentiate of the College for three years at least computed from the day on which he shall have subscribed his name on admission as a licentiate, unless he be on that day either a graduate in arts of a university in the United Kingdom, or a registered practitioner of seven years' standing, in which case the interval is reduced to one year.

How the Military Authorities Treat the Medical Service.

A correspondent of the *Lancet* calls attention to the fact that, though Surgeon-Major Reynolds was considered deserving of the Victoria Cross for his conduct at Rorke's Drift, nowhere have we seen that the Commander-in-Chief noticed his gallant services, and honoured him in the manner he did Major Chard at Portsmouth, although they arrived in the same vessel.

Again, Major Chard was honoured with a command to appear before Her Majesty at Balmoral ; but no such honour for Dr. Reynolds. He has instead been ordered to report himself to the principal medical officer, Ireland, for duty there ! Is it not very disheartening that such invidious distinctions should be made ?

Suicide of a Scotch Medical Man.

A medical man belonging to or connected with Greenock, who recent went to Newcastle from Staffordshire to seek an engagement as doctor's assistant, was found a few days since in his bedroom at his lodgings, lying insensible on the floor. He had poisoned himself. Near him was found a note addressed to his wife in Glasgow, in which he requested to be buried in the Greenock Cemetery. It was stated at the inquest held on the body that the deceased had lost £3,000 by the failure of the City of Glasgow Bank.

Tetanus Following the Abuse of Hypodermic Injection.

Last week a strange death occurred in Jervis-Street Hospital, Dublin. A lady, aged about 35, named Frances Chapman, a governess, was admitted into the hospital, suffering from an acute attack of tetanus. It appeared that for many years the unfortunate lady had been subject to a severe neuralgic affection, causing her the most dreadful agony. In order to allay the pain she had been latterly in the habit of employing subcutaneous injections of morphia ; the habit grew upon her, until finally, she had been accustomed to inject a quantity of four grains of the hydrochlorate of morphia at a time. She was attended by Dr. Austin Meldon, surgeon to the hospital, the symptoms of tetanus being fully developed when he first saw her. Her person was tatooed with "millions" of hypodermic punctures.

Pepsine.

In the French Academy of Medicine, M. Vulpian has called attention to the fact that pepsines delivered from different pharmacies vary much in their digestive power, some of them modifying albumen so slowly as to make it doubtful what good effect they can have when administered to dyspeptics. He also confirmed a conclusion arrived at some time ago by Dr. Symes (*Pharm Journ.*), that the action of pepsine is retarded by the presence of alcohol. Wines and elixirs of pepsine are very much used in France, and as M. Vulpian went on to say that some of the most renowned elixirs contained an extremely small quantity of pepsine, the rest intended to have been present having probably been precipitated by the alcohol during the manufacture of the preparations, the statement has caused some little sensation amongst the makers.

The Sanitary Congress of 1879.

That the general public take but little interest in sanitary matters was never more fully exemplified than at Croydon last week. In the same town but a short time ago a "Church Congress" was held; the excitement was intense, meetings were packed with attentive listeners, and in some instances hundreds were unable to gain admission. Last week a casual visitor would have been surprised to learn that a Congress was being held there, still more so had he been taken to the exhibition of sanitary appliances, to find that such a magnificent display had not attracted more attention, or the meetings at which valuable papers were being read were so sparsely attended. Yet so it was, and it must be discouraging in the extreme to such enthusiastic sanitary reformers as Dr. Carpenter, Dr. Richardson, and others, to find their efforts so meagrely appreciated. Divines will tell us that it is very right and proper that men should think more of their souls than their bodies, and that they should esteem it a higher privilege to attend the religious than the sanitary congress; but we should like to see more of them practically adopting the tenets of scriptural doctrines on the principle that as "cleanliness is next to godliness," time might not be unprofitably spared in the study and practice of both.

Gas Works Refuse.

It is a question worth asking, what becomes of the ammoniacal refuse from the manufacture of gas? It is too readily, we believe, assumed that this is a marketable commodity of value sufficient to induce the gas companies always to convert it to the crystalline form for sale. The process for effecting this is not one of the simplest or cheapest, and where no special incentive to preservation of the material exists, we have reason to assume that its disposal carries with it germs of danger to public health. In certain country places, the liquor is undoubtedly passed into running streams in the close neighbourhood of the gas-works; and complaints from those living along such watercourses, of the inconvenience they suffer from bad smells, are by no means uncommon. Is such disposal of the ammonia-charged refuse usual in the metropolis? We think it is; and if so, that herein is one cause at least of the filthy condition of the mud wastes exposed along the banks of the river at every fall of the tide. An inspection of the books of each gas company would at once reveal the truth or otherwise of the assumption. The advisability of instituting an inquiry in this direction is obvious.

Counter Practice in Australia.

The counter practice controversy appears to have spread to the Antipodes, Dr. Bowker having introduced into the New South Wales Legislative Assembly a Medical Bill which the chemists and druggists of the colony condemn as ignoring the rights, customs, immunities and privileges secured to them by the Imperial legislation in the Apothecaries Act of 1815. At a recent annual meeting of the New South Wales Pharmaceutical Society, a petition was adopted asking for the erasure of the obnoxious clause and the insertion of one repeating the saving clause of the Apothecaries Act; the construction of which has furnished so much food for argument in this country.

Ergotine.

Dr. Eldridge, surgeon to the General Hospital at Yokohama, Japan, recommends (*New York Medical Journal*) the topical use of ergotine in acne rosacea, granular urethritis, gonorrhœa, and otitis media. The general principle of his treatment consists in influencing the arterioles directly by means of the ergotine, either by external application or by subcutaneous injection. For the latter he employs a preparation compounded of ergotine gr. xv., glycerine ʒss., water ʒij., and injects two minims into the substance of the skin at intervals of three days (in reduction of vascularity of an alcoholic nose). In cases of granular urethritis with chronic gleet, after division of any stricture that may exist, Dr. Eldridge has employed the remedy pure, "by means of the ointment syringe, after evacuation of the bladder, and thorough irrigation of the canal by warm water, the application being followed by an hour's recumbency. Six applications on alternate days effected a cure, the gleet entirely disappearing, and no traces of granulations being visible by the endoscope." The ergotine has been found to cause no pain or irritation, and, in the urethra, can be conveniently applied by means of a swab of lamp cotton attached to a thin bougie. The end of the cotton being held outside the meatus, on withdrawing the bougie, the cotton can be left in any situation as long (half an hour) as may be desired, and then easily retracted by pulling on the free end. The success that has attended Dr. Eldridge's experiments warrant the assumption that the ergotine may with advantage be employed as a means of reducing any obstinate hyperæmia in which topical applications are admissible.

The Mortality in Dublin.

The city death-rate, which had fallen within a few weeks to a little over the most unhealthy cities of Great Britain, has again risen. The deaths during the week ending 18th October represent an annual mortality of 32·6 in every 1,000 of the population. The average in eight large town districts of Ireland (including Dublin) was 24·0 per 1,000. In twenty large English towns (inclusive of London) the death-rate averaged 20·9; in Glasgow 16·1; and in Edinburgh 16·8. Forty-six deaths from zymotic diseases were registered in Dublin during this week, being 19 more than in the preceding week, and 10 over the average of the 42nd week of the last ten years. They include 14 from small-pox, 2 from measles, 9 from scarlatina, 1 from diphtheria, 4 from croup, 2 from fever, (both typhus cases), 5 from diarrhœa, 2 from purpura, &c. Six of the 14 deaths from small-pox occurred in the Meath Street District, where ten deaths from that disease were recorded in the course of the preceding ten weeks, and 6 of the 9 deaths from scarlatina are chargeable to Denzille Street and Grand Canal Street District, making 25 fatal cases of scarlatina in this district during the last twelve weeks. The registered deaths from small-pox are 12 in excess of the number in the previous week, and are double the average number in five weeks preceding. Thirty-two new cases of this disease were admitted into the Dublin Hospitals last week, against 36 in the preceding week, and 17 in that ending 4th inst.

THE French Minister of War has authorised the wearing of spectacles by soldiers on duty, subject to certificates of the military surgeons of their being necessary.

W. B. SAUL states, in the *Pharm. Journ.*, that the most simple and easy way of detaching leeches is to drop a few drops of camphor water on the part, and they will soon relinquish their hold.

AT the first meeting of the Twenty-third Session of the West Kent Medico-Chirurgical Society, Dr. Prior Purvis, Blackheath, was elected President for the ensuing year.

LAST Sunday, collections were made in the various places of worship in Birmingham, in aid of the hospitals of that town. It will be remembered that "Hospital Sunday" originated in Birmingham.

DR. WILKS, of Guy's Hospital, has been appointed Physician to their Royal and Imperial Highnesses the Duke and Duchess of Connaught, in succession to Dr. Murchison, deceased.

DR. BLACKBURN has been elected Governor of Kentucky. He was charged with being the physician who, during the civil war, endeavoured to infect Northern cities by shipping to them the clothes and bedding of yellow fever patients. This charge he neither denied nor confessed, declining to make any reference to ii.

THE death-rate last week from scarlet fever showed the largest proportional fatality in Newcastle-on-Tyne, Liverpool, Leicester, Manchester, Sheffield, and Sunderland. Diphtheria caused 2 deaths in Liverpool, Plymouth, and Birmingham. The deaths from measles were numerous in Leeds and in Liverpool. One fatal case of small-pox was recorded in London, 14 in Dublin, but not one in any of the other large towns.

ACCORDING to the Registrar-General's returns the rates of mortality per 1,000 last week in the principal large towns were—Brighton 12, Portsmouth 13, Wolverhampton 14, Bristol 15, Glasgow 16, Edinburgh 17, Newcastle-on-Tyne 17, Birmingham 18, Leeds 18, Oldham 18, Sunderland 19, Nottingham 19, Leicester 20, Plymouth 20, London 22, Manchester 22, Bradford 22, Sheffield 23, Salford 23, Hull 23, Liverpool 26, Norwich 26, and the highest rate of all, 33 in Dublin.

AN untoward and unexpected event tends to compromise in some degree the perfect success of the Dublin Sanitary Commission. As stated in our last, Mr. Dixon, its secretary, was found dead in his bed, having been slightly ailing for a few days. Mr. Dixon was son of Mr. Hepworth Dixon, of the *Athenæum*—and we understand—was the subject of heart disease, which had followed upon a severe wetting got in an attempt to save life. We learn with much satisfaction that Mr. Robert O'Brien Furlong, Q.C., who represented the Sanitary Association so efficiently at the sittings of the Commission, has been appointed to the vacant secretariat.

AN inquest was held last week at Scarborough, touching the death of a woman, æt. 40, who expired somewhat suddenly. The case was an ordinary one, made extraordinary by the length of the inquiry, lasting from seven o'clock in the evening until half-past one the next morning. We are sometimes told that, were coroners lawyers instead of medical men, inquiries would be of a much more business-like nature; the Scarborough coroner being "a gentleman of the long robe," furnishes us an excellent illustration to the contrary, as we fail to see that a "death from inflammation of the lungs" in a patient attended by legally qualified practitioners, needed so protracted an investigation.

IN the principal foreign cities the rates of mortality, according to the most recent weekly official returns, were —in Calcutta 24, Bombay 38, Madras 38; Paris 22; Geneva 25; Brussels 27; Amsterdam 23, Rotterdam 21; The Hague 23; Copenhagen 26; Stockholm 18; Christiania 15; St. Petersburgh 31; Berlin 26, Hamburg 26, Dresden 21, Breslau 28, Munich 34, Vienna 24, Buda-Pesth 30; Rome 35, Naples 23, Turin 27; Alexandria 40; Brooklyn 21, Philadelphia 15, and Baltimore 19 per 1,000 of the population. Small-pox caused 19, and typhoid fever 22 deaths in Paris.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

ANDERSON'S COLLEGE, GLASGOW.—A largely-attended meeting of the managers of this institution was held on the 20th inst. for the purpose of electing a Lecturer on Aural Surgery, Mr. Jamieson, President, in the chair. Before proceeding to the election, Mr. Jamieson said that the College was never in a better state of efficiency as regards "professors," and lecturers than at the present moment. The want of proper class-room was very much felt, and the dilapidated condition of the buildings generally was a subject that caused considerable anxiety to the managers; and, considering what the College was accomplishing, he hoped that all the trustees would put their shoulders to the wheel when trade revived, and do all that they can to obtain funds adequate to raise a building worthy of the name of Anderson's College. The election of Aural Lecturer was by ballot; and Dr. Barr had a clear majority of votes over all the candidates, and was accordingly elected.

THE ASSUMPTION OF MEDICAL TITLES IN GLASGOW.—Gentlemen, Licentiates of the Faculty, and of the Edinburgh College of Physicians, who has conferred your degrees upon you? Has the Faculty of Physicians and Surgeons nothing to say against the assumption of the prefix "Dr." by its mere licentiates? Titles confer no dignity on men; 'tis men who confer dignity on titles.

DEATH FROM THE BURSTING OF A VARICOSE VEIN.—A quay labourer residing in Glasgow is charged with having caused the death of his wife by a kick on the leg, a varicose vein having been thus burst, and the woman having bled to death. The woman is said to have been under the influence of drink at the time.

REGISTRAR-GENERAL'S RETURNS.—According to the weekly return of births, deaths, and marriages, the death-rate in the eight principal towns of Scotland during the week ending with

Digitized by Google

Saturday, the 18th October, 1879, was 16·6 per 1,000 of estimated population. This rate is 1·6 under that for the corresponding week of last year, but 0·7 under that for the previous week of the present year. The lowest mortality was recorded in Perth, viz., 9·8, and the highest in Paisley, viz., 25·5. The mortality from the seven most familiar zymotic diseases was at the rate of 3·2 per 1,000, being the same as that for the previous week. There was an increase of deaths from croup and diphtheria and whooping-cough, while diarrhœa shows considerable diminution. No deaths from any of these diseases occurred in Greenock. Acute diseases of the chest caused 75 deaths, being 9 more than the number recorded during the previous week.

Death-Rate of Glasgow.—The deaths in Glasgow for the week ending Saturday the 18th inst., were at the rate of 16 per 1,000 per annum. In the preceding week the rate was 18 per 1,000, and in the corresponding week of each of the years 1876, 1877, and 1878 it was 21.

Obituary.

GEORGE WM. CALLENDER, F.R.S.

This well-known surgeon died on board a steamer on his return from a tour round the hospitals of the United States, where he had met with a warm welcome. Mr. Callender was Surgeon to St. Bartholomew's Hospital, and was Lecturer on Surgery in the Medical School. He was a sound, earnest teacher, and his recent advocacy of the plan of treating chronic abscesses by hyper-distension with carbolised water, attracted much attention to the plan both at home and abroad. At one time Mr. Callender was Lecturer on Anatomy to the Royal College of Surgeons, and was also an Examiner in the Royal College of Physicians, and to the University of London. A few years ago he was elected a Fellow of the Royal Society. Mr. Callender held an high place in Surgery, and deservedly so. He was comparatively but a young man when his course was cut short by Bright's disease. It had been known to his friends for some time past that he was the subject of chronic kidney mischief with albuminuria. Mr. Callender's loss will be keenly felt at St. Bartholomew's Hospital and Medical School.

ARTHUR LEARED, M.D., F.R.C.P.

Everyone will miss the pleasant cheerful face of Dr. Leared, who has recently died of typhoid fever caught during a recent tour in Tangiers. Dr. Leared was a great traveller and a good linguist. He paid much attention to Iceland, and he published in Icelandic "a Plan for the Prevention of the Fatal Cystic Disease of Iceland." He also was much interested in Morocco and the Moors. He is best known to the profession by his works on "Dyspepsia." He also studied carefully the sounds of the heart. He was Senior Physician to the Great Northern Hospital at the time of his death. At one time he was Lecturer on Practice of Medicine at the Grosvenor Place School of Medicine. He was at one time Physician to the Royal Hospital for Diseases of the Chest, leaving it at the same time when Dr. W. Richardson withdrew his services from it. In his early days Dr. Leared was Physician to the British Civil Hospital at Smyrna. Few men were more popular among the profession than the late Dr. Leared.

THE LATE DR. BERNAND KAVANAGH, OF LIMERICK.

We regret to announce the unexpected death of this popular member of our profession. Born in the year 1823 of an old and respectable family in Carlow, a family which gave many distinguished members of the profession which he himself afterwards adopted, he prosecuted his studies with marked success in his native town. Some years later he passed to the University of Glasgow, where he obtained his degree. He was next known in the schools and public hospitals in Paris, where he spent about three years, and returning to Ireland he placed himself under the instruction of Sir William Wilde, for the study of eye and ear diseases, and of Dr. Stokes for internal diseases of the heart and lungs. So fully did he profit by the instructions of this latter that he gained from him the Stethoscopic prize, the highest honour then attainable by a medical student in Ireland. It was soon after this that he published his essay on the "Antagonistic Properties of Belladonna and Opium" in the *Medical Press and Circular*, a very valuable contribution to medical literature. He quickly rose to that eminence his instructors had unanimously anticipated for one so promising as a student.

Correspondence.

"THE TITLE OF DOCTOR."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—That interesting individual, the "penny-a-liner" of the lay press, being sometimes driven to hard shifts for "copy," has generally a fertile resource in tales of a big gooseberry; the sea serpent; the freezing into temporary death of live animals; and their restoration to life again by boiling in hot water, and as *un dernier ressort*, the plotting and executing—*on paper*—of a more than usually savage and sensational murder. With such a number of interesting subjects to fall back upon in periods of dulness, such as the long vacation when both the "House" and the Law Courts take their repose, he contrives to sustain both his reader's curiosity and the wants of his own stomach by the due exercise of his "noble art." In this respect he far outvies his professional brother of the medical press, for—unfortunately for him—the refinements of professional journalism restrain him in every difficulty to the hackneyed theme of "The Title of Doctor." I am driven to make these (no doubt unpalatable) remarks by the quotation in your issue, Oct. 15, of "the observations of a correspondent" of one of your contemporaries, and by your own observations thereon, which appear to me, a simple general practitioner, to say the least of them, a little too severe.

In such a case as this, every man interested possesses a right to be allowed to speak for himself, and claiming this right, I now proceed. Know, then, Sir, that I am a general practitioner (L.R.C.P. and Surgeon), practising in a rural district embracing many villages, and surrounded by many general practitioners (a few M.D.'s among those), and that I never "try to appear bigger . . . . by parading in borrowed plumes;" nor because being simply a "captain" do I want to be considered as "big or as good as any "major." In all my dealings with my patients and the public I wish to be addressed as "Mr.," and I am quite content to designate myself by the somewhat hybrid (but nevertheless legal) title of physician and surgeon.

If all M.D. degrees—but especially British M.Ds.—were of the same standard currency, I might then evince my anxiety to appear to be one, if "brains, time, and money" failed me in my attempts thereat; but as long as some degrees represent a currency of 22 carats, some 18, some 12, others 6, and others still an aluminium or gilded bronze value, I much prefer to remain simply "*Mr. Gouger Chiselhem*, Physician and Surgeon." Nor is my opinion of the value of the M.D. degree much improved by the attainments and the practices of the M.D.s, my neighbours, my brother artists, and my rivals. While I charge a minimum fee of a guinea for midwifery, and a fee of "two-and-six" for a "home" visit, with "physic," extra "two-and-six," my neighbour M.D.s are glad to accept of midwifery at "any price" "from half-a-guinea;" and they charge *nothing* for visits or advice, but for bottles of "physic" only. Again, I am bothered from time to time by sundry queer fellows—Odd Fellows and others—who inform me that their "lodge" is in want of a doctor, and inquire if I will make a "bid"

Digitized by Google

for it (the lodge). They make "tracks" themselves, however, when informed of my terms; and my next information is that Dr. Sampson Sawdust, M.D., is the chosen man of the lodge, at an annual payment of three shillings sterling per Odd Fellow—advice, attendance, physic, and all sick and other "lines" included. When I say further that such of my M.D. competitors who "go in" for a sixpenny colliery club practice are known to have an occasional dispute with their "clubbers" over an extra penny a fortnight for physic and advice, I think I may here now most fittingly conclude my "catastrophe," and leave to others the continuation of the tale from their own experiences.

I am yours, &c.,

GOUGER CHISELEM, L.R.C.P., &c.,
Author of "Medical Men and Manners."

18th October, 1879.

THE PORO-PLASTER JACKET.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Allow me space for a few brief and practical remarks, as a supplement to Mr. Ormsby's article, which appeared in your issue on the 15th of October.

The value of the theory of applying a plastic support during suspension, or in other words placing the spine in the best position for rest and recovery, and then keeping it there, I shall take for granted, and confine my remarks to a comparison of the respective value of poro-plastic and plaster as agents for carrying this purpose into effect—not forgetting that poro-plastic can be applied with advantage where suspension would be unwise. In short, that poro-plastic judiciously used does all for which spinal mechanism has been hitherto used, and does it much better. But good results are not to be gained by unskilful applications; and surely the subject is one worthy of attention and study by all those who undertake to treat cases of spinal disease.

I have seen both plaster and poro-plastic applied in such a manner, that to expect good results would be to expect a miracle; and yet the application of the poro-plastic jacket is about as easy, rightly understood, as applying a bandage. The surgeon, or surgical mechanist, should select a jacket the size and shape of the patient. Where the distortion is extreme, either angular or lateral, or both in combination, a jacket should be made specially for the case. The jacket should be thoroughly softened all over before applied, and during application well worked in around the waist and over the hips; then well bandaged round, afterwards laced, and two screws—one at the top, and the other near the bottom—used to fasten the over-laps together and prevent any shifting up and down.

The causes of failure arise from trying to make jackets out of sheet poro-plastic (unless the trunk is almost straight, as in young children this cannot succeed). The felt must be shrunk into the required shape in manufacturing it, and before being stiffened. Mr. Sayre's failure to apply felt successfully arises from overlooking or not knowing this, from expecting too much plasticity from the felt. Felt is plastic, and will extend whilst hot in any required direction a certain distance, but not far; try to make it go further, and it flies into wrinkles. From not using felt thick enough for the purpose—to this mistake I think most of the giving way and going soft is to be attributed—it need not occur; a felt jacket, of the strongest make, and one which would bear anything up without giving way, need not be one-quarter the weight of the plaster jacket. About twelve hundred are now in use. I have heard of but few failures, and I believe Mr. Wm. Adams expressed the conclusion arrived at by our leading surgeons, when after my demonstration before the Association at Cork, he said: "I have had much experience with plaster and poro-plastic, and much prefer poro-plastic, and find my patients prefer it also." On my return from Paris, where, with M. St. Germain, I have to demonstrate my method before the surgical schools, I purpose making a lengthened stay in London, and shall be pleased to give any practical information to medical men or surgical instrument makers interested in the subject, and show them the appliances I have found most efficient.

Yours respectfully,

J. T. COCKING.

Plymouth.

THE "WELL-READ SWINDLER" OR LETTERED SYMPATHY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The letters in the *Times* on the accomplished German gentleman who has so successfully fleeced our profession and the church alike, have drawn leaders on the subject from the *Daily News* and the *Daily Telegraph*. They both estimate his ill-gotten gains at "a few shillings;" I wish it only had been so.

When a handsome, gentlemanly man, speaking English well, and grammatically, but with a distinct accent, as if he had learned it from books rather than by the *vox viva*, the first impression is in his favour on seeing him in one's consulting room. When his next act is well-feigned—no! my vanity tells me unmistakeably *that* was genuine astonishment at the comparative youthfulness of the author of so many books; for has not my experience furnished me with numerous-like instances of such surprise. When this genuine astonishment produces its natural effects, the operator, by accident, gets a strong card put into his hand to play on his victim. His way is comparatively clear, and his course of operation much facilitated. Then comes apparent familiarity with one's writings; that appreciation of their value from an educated foreigner, which is so pleasant, so sweet, because so free from any bias. One's suspicions are largely laid at rest; and it becomes a question whether this is a fraud or a case of genuine misfortune occurring to a brother man of science; who pays one the compliment of coming to one when overtaken by a mischance. A broad honest-looking face, with such sincere indignation at the scoundrels who robbed him of his holiday, and the opportunities of reading at the British Museum and the Bodleian at Oxford; it is this which he regrets, the mere money loss he does not even mention: it is too much for the representatives of medicine and the church; they both backed their knowledge of physiognomy—and lost. It is not the money loss the afflicted gentleman bewailed; his devotion to his work was thorough,—he was crippled in his studies. After receiving the loan, which will enable him to telegraph to his bankers, and to proceed to Oxford; his solicitousness next takes the direction of how shall he make repayment, about which he is most anxious. He may return the loan personally; at which he is delighted, as it permits him to add further to his acquaintance with the author, whose works he so admires, and whose good-natured kindliness has so readily relieved him from his dilemma. Finally, on going out, he adds some counsel, "Do go on working; do not do as some men do, and say 'Oh! I have done enough. I have made a reputation. I need not do any more work.' Do not do that Dr. ——. Your work is so good. Do go on working." (Well, I intend to take this apparently disinterested advice anyhow.) The accomplished deceiver departs, and one feels a glow of pleasureable emotion at relieving a brother-worker in a strait: humanity looks all the better for this mutual confidence betwixt men of culture and of letters. Slowly only, does one awaken up to the full consciousness that the foreign admirer of one's labours is an accomplished impostor; and that one's confidence in one's powers to read character is not as well-founded as one had supposed. There is something specially detestable in this scientific study of the art of fraud. The apparent artlessness of the story; its vraisemblance; the ready confidence displayed in other men of letters: the compliment involved in coming to one, as indicating the estimate of one's character, as formed from the study of one's written works: all combine to anæsthetise one's suspicions. Then the good counsel thrown in at the last rivets the shackles which vanity had thrown away the judgment, and the stern pressure of facts is required to disillusionise one. The *Daily Telegraph* concludes its leader:—"A swindler who has Darwin and Strauss at his fingers' ends, is a very remarkable person, and marks a new era in the history of imposture." Well, that rather soothes one's wounded vanity; but it does not restore the sovereigns thrown away. It is not pleasant to be "done brown;" still, I would rather be open again to be done by so clever a tale than have to maintain an attitude of suspicion so perfect that it could successfully repel the attack of so accomplished a scoundrel. I should certainly like to see whether his performance on the treadmill is on a par with his capacity for imposture. The attention attracted by the skilful work of "Dr. Plieth," will probably put other men on their guard, and prevent their following the example of the swindled

Queen's University in Ireland.—The following degrees were conferred on October 15th :—

Doctor in Medicine.—First Honour Class: James Barron, W. E. Ashley Cummins, Sinclair White. Second Honour Class: J. W. Macnamara, Robert Mowbray. Upper Pass Division: John Acheson, Thomas M. Corker, G. H. D. Gimlette, Myles O'Reilly, Taylor Reynolds, John Smyth, Samuel A. Strahan, T. Kennedy Wheeler. Lower Pass Division: Henry K. Allport, Myles H. Atkinson, Wm. Atkinson, Augustus H. Bampton, J. W. Beatty, Wm. James Cowden, Joseph Crowley, Samuel Dickey, Thomas Dorman, John E. Dowling, John Eadie, Alexander C. Fraser, James Geraghty, Hugh Greaney, Edward Hanly, Patrick C. Hickey, James Frank Holland, John Hosford, John E. Lane, Samuel G. Levis, Henry M'Cormick, John M'Cormick, Thomas P. Madden, Charles Magill, Samuel M. Malcolmson, John Martin, Andrew S. Mitchell, Charles A. P. Mitchell, Robert Mitchell, George R. O'Donovan, Thomas O'Kelly, Alexander Sharpe, Jacob Thomas Shipsey, John Simpson, William Smyth, Alexander C. Suffern, Horace R. Townsend, John Vint, John Watson, David L. Williams, James Wilson, William Mussen Young.

Master in Surgery.—John Acheson, Henry K. Allport, Augustus H. Bampton, James Barron, William Henry Bracken, Thomas M. Corker, Joseph Crowley, W. E. Ashley Cummins, Samuel Dickey, Thomas Dorman, John E. Dowling, A. Osmonde Geoghegan. G. H. Desmonde Gimlette, Hugh Greany, Edward Hanly, Gilbert Kirker, John M'Kinlay, Thomas P. Madden, Charles Magill, Samuel M. Malcomson, Charles Mitchell, Robert Mitchell, Robert Mowbray, Thomas M. O'Brien, T. Taylor Reynolds, Alexander Sharpe, Jacob Thomas Shipsey, John Smyth, Samuel A. Strahan, Alexander C. Suffer, Horace R. Townsend, John F. Tuohy, Sinclair White, David L. Williams.

British Medical Association.—The following is a list of grants in aid of scientific investigation which have been made by the Association :—Dr. Ogston: For the research into the relation between Bacteria and Surgical Diseases, £50; Mr. W. North: To discover what, if any, relation exists between the Nitrogenous Egesta and Muscular Work, £50; Dr. Ewart: To continue his research into the Life-History and Pathological Relations of Specific Organisms already known, and for the discovery of other similar organisms and the channels through which they enter the system, £10; Dr. Crocker: To continue his research on the Physiological Action of Alcohol, with especial reference to its mode of elimination, £24 5s; Dr. Thin: To continue his research into the Nature and Development of Conditions of Life of the Vegetable and Animal Parasites that infest the Human Skin, £5; Mr. Chiene: To continue his research on the subjects (1) Are there present in Organs of Living Animals Particles which originate the Bacteria met with after Death? (2) Do the discharges from wounds which are antiseptically treated contain organisms? £15.; Dr. Barlow: To continue an experimental Investigation into the Changes produced in the Blood-vessels by Alcohol, £8; Dr. Ferrier and Dr. Gerald Yeo: Researches with the view of Testing the Application of Antiseptic Surgery in Cases of Lesion of the Skull, Brain, and its Membranes, £50; Dr. Newman: Research on the Functions of the Kidney and on the Physical Conditions which regulate the flow of Urine, £10; Mr. Malcolm Morris: An Investigation into the Anatomical characters of certain diseases of the Skin allied to Tubercular, Scrofulous, Typhoid, and Syphilitic Affections, £10; Dr. McKendrick: Investigation on Anæsthetics, £50.

NOTICES TO CORRESPONDENTS.

FOREIGN DEGREES.

To the Editor of the Medical Press and Circular.

Sir,—I wonder where the men "were educated" who go over to a foreign country and publicly proclaim that they do not know French by submitting to an examination in English.

Dr. Carpenter, in his discussion with the foreign graduates, has omitted this point.

Yours faithfully,

Oct. 1879. F.R.C.P.L.

To the Editor of the Medical Press and Circular.

Sir,—What is the good of Durham University? What is the use of its faculty in medicine? Can any one answer this question? As a Northern University it is situated in a good position, and should give better results. Has any one *ever* seen or spoken to a graduate in medicine of this seat of — learning?

Might not it then open its portals to those gentlemen who are now crossing the Channel to Brussels, Giessen, &c,

Yours truly,

Oct. 1879. A Word to the Wise.

One who intended being present.—The Congress was a success in some respects, but the attendance fell short of expectations.

F.R.C.S.—The rumour is unfortunately true.

Literate.—Probably in our next.

To the Editor of the Medical Press and Circular.

Sir,—Are foreign degrees recognised by English law? Can Englishmen hold such degrees, or accept them, without the consent of the Crown?

Yours,

Oct. 1879. Scrutator.

Odontological Society of Great Britain.—On Monday, Nov. 3, at 8 p.m., Ordinary meeting. Communications from Mr. C. S. Tomes, F.R.S., and Mr. Hutchinson.

A Vivisectionist's Pipe.—In last Saturday's *Anti-Vivisectionist* the Editor remarks that "Some one, who, we must take it, is a sincere believer in the merits of vivisection, has sent us a page of this week's *Medical Press and Circular*, containing a part of Canon Duckworth's address at the Westminster Hospital, with a kind recommendation to "put it in our next editorial pipe and try and smoke it out." Whoever the "sincere believer" may be, we think he might send a more pleasant smoking mixture for the editorial pipe, as the conductors of that publication are not unnaturally of the opinion that *le feu ne vaut pas la chandelle*.

A Dispensary Medical Officer asks—1. Is there any rule which prohibits the medical officer of a dispensary from giving medicines out of that institution to none others but to those who present a ticket to him; and further, is it lawful for him to keep a certain quantity of the medicines supplied to him by the Poor-law in his own private residence, as often the dispensary is situated some considerable distance from there, and in cases of emergency, as midwifery, &c., it is very inconvenient to have to go to the dispensary to make up the necessary medicines? 2. Have the Local Government Board any rule or bye-law in existence as to who or what qualifications are necessary to constitute a pauper, or is there any fixed rule as to who members of dispensary committees are to give tickets or what circumstances should the recipient of such ticket be in to justify the medical officer in bringing that individual case before the committee at the first meeting with a view to have such ticket cancelled. There is a rule among the several members of the committee in the dispensary to which I belong that they will not give a ticket to any man who has got two milch cows; whereas, other men who are in *much more* opulent circumstances, and have got twice as much land, &c., and income from other sources, but still have only got one milch cow, demand a ticket and get it, because they do not come under the above rule. I have often complained to members of the committee of the injustice of issuing tickets in this manner, and they have advised me to appeal for your advice on the subject in your influential journal, not only for my own preservation, but for their better guidance, and that of dispensary committees in general throughout Ireland, as they know of no better way to finding their discretion. 3. When called into a midwifery case on a red ticket, very frequently no medical assistance of any kind is required, am I bound to remain in that cabin for any length of time till the process of labour is completed, though I find everything natural and not, in my opinion, requiring more than I have already done. I am constantly tormented with cases in which I am sent for, and when I visit the patient I find that labour has not actually begun at all; yet the insolent and intolerant people with whom I have to deal refuse to allow me to leave their abode till *all is over*, and that if I do so I shall be visited with the pain of instant dismissal, as they will make a complaint to one of my *learned* masters (or one of the committee) on the subject. This is a very hard case I have had often to endure, and what makes it worse is, that I have had three other red tickets in my pocket requiring attendance at the same time, and all equally turbulent, and complaining that I was not with them also. I hope to give you some experience of dispensary life on an early occasion that will be more interesting to your readers, in lieu of the information which I now request that you will be kind enough to give me.

[1. There are no distinct rules on these points, but both practices would be quite irregular and contrary to usage. In exceptional cases departures from rule may be allowed, and—we imagine—no serious objection would be raised either to the giving of dispensary medicines to persons who do not present tickets, or to the keeping of a small supply at the medical officer's house. But, of course, no dispensary medicine should, under any circumstances, be given to any but a really "poor" person. 2. There is no definition of a "poor" person, and the Local Government Board has, intentionally, abstained from giving such definition, desiring to afford the widest latitude to dispensary relief. The dispensary committee alone is empowered to form its own opinion as to whether any recipient of a ticket is or is not "poor," and, we believe, it is not *en règle* for them to apply any rigid rule in the matter. The legitimate recipient of dispensary relief is, in fact, a person whom the committee considers "poor," and much depends on the class of persons who form the committee. 3. You are bound to remain as long as—in your best judgment—the safety and welfare of your patient makes it necessary, and no longer. You are responsible for the case, and are bound by nothing but your own sense of what is requisite for the patient. You need not trouble yourself whether the patient's friends desire your attendance or not.—Ed.]

THE PROFESSORSHIP OF MEDICINE IN GALWAY.

To the Editor of the Medical Press and Circular.

Sir,—My attention having been drawn to the *Medical Press and Circular* of the 15th inst. where, under the above heading, the name of Dr. Nolan appears amongst the candidates for the vacant chair of medicine in Galway. If I am the person there alluded to, I will thank you to correct the statement in your next issue.

I am not a candidate, nor have I ever sought any appointment in connection with the Queen's College.

Faithfully yours,

Gort, Oct. 25, 1879. A. O'Kelly Nolan, F.R.C.S.I.

Digitized by Google

THE annual general meeting of the Medical Society of the College of Physicians, Ireland, will be held this evening (Wednesday), chair to be taken at half-past eight. Business: 1. The Election of Officers and Council. 2. Consideration of Amendment of Rule I. of the Society, as proposed by Council.

INQUIRER asks if a medical officer receives a visiting ticket to visit a person in his district, who is reported as being of unsound mind, he visits and examines the said person, who is a dangerous lunatic in his opinion, what is his exact duty as regards the filling up of the medical certificate attached to the information paper? Can he legally refuse to do so until called on by the magistrates before whom the lunatic is brought?

[He must visit if served with a red ticket, but he can, and should, refuse to certify. He should either inform the police himself or see that the patient's friends inform them that the patient is dangerous. The police will then apprehend him and bring him before a magistrate who, under sec. 10 of the Dangerous Lunatic's Act (30 and 31 Vic., cap. 118, "Irish Medical Directory," page 492), will then summon "the nearest available medical officer of the district in which he shall be at the time," who will then certify, and be entitled to a fee for so doing.—ED.]

A HATER OF QUACKERY.—We have exposed the charlatanism of "Dr." Evans on several occasions. We should like to know that his name was erased from the roll of his college and from the "Register." Our correspondent should bring the matter officially before the authorities.

VACANCIES.

Castlerea Union, Castlerea Dispensary.—Medical Officer. Salary, £100. with fees, and £25 as Medical Officer of Health. Election, Nov. 1.

Chipping-Norton Union.—Medical Officer for District No. 2. Salary, £65. Also for Workhouse. Salary, £40. Applications to the Clerk before Nov. 4.

Northampton General Infirmary.—Resident Medical Officer. Salary, £100, with board. Applications to the Secretary before Nov. 3.

Royal Free Hospital, London.—Assistant Surgeon on the Staff. Applications to the Secretary on or before Nov. 26. (See Advt.)

Royal College of Surgeons of England.—Examinerships in Anatomy and in Physiology. Applications to the Secretary before Nov. 1.

Leeds Union.—Assistant Medical Officer to the Workhouse Infirmary and Schools. Salary, £100, with board. Applications to the Clerk to the Guardians before Nov. 1.

Warwick County Lunatic Asylum.—Junior Assistant Medical Officer. Salary, £100, with board. Immediate application to the Medical Superintendent at Hatton, Warwick.

Kent and Canterbury Hospital.—Assistant House Surgeon. Salary, £60, with board. Immediate application to the Secretary at the Hospital, Canterbury.

Banbridge Union, Tandragee Dispensary.—Medical Officer. Salary, £100, with fees, and £20 as Medical Officer of Health. Election, Nov. 5.

Births.

NOAD.—On Oct. 23, at Lower Norwood, the wife of Henry Carden Noad, L.R.C.P. Lond., of a son.

BALL.—On Oct. 19, at 16 Lower Fitzwilliam Street, Dublin, the wife of Charles B. Ball, F.R.C.S.I., of a daughter.

OULTON.—On Oct. 20, at Ballickmooler, Queen's co., the wife of Henry W. Oulton, M.D., of a son.

Marriages.

TUKE—NEWINGTON.—On Oct. 23, at St. Mark's Church, London, W., George Montague, second son of the Rev. Francis Tuke, to Helena, daughter of Dr. S. Newington, of Tickhurst, Sussex.

O'DEA—LYNSKEY.—On Oct. 16, Patrick St. Laurence O'Dea, L.R.C.P., Oranmore, co. Galway, to Kathleen, daughter of Thadeus Lynskey, Esq., Ashgrove, Foxhall.

O'DONOVAN—JORDAN.—On Oct. 14, at Ballybrack, co. Dublin, Jeremiah O'Donovan, M.D., Mount Haigh, Kingstown, to Mary Jane, eldest daughter of Charles Bourke Jordan, Esq., of Thornhill, co. Mayo.

Deaths.

ARNOTT.—On Oct. 16, at Kirkconnell Hall, Ecclefechan, F. S. Arnott, M.D., C.B., Honorary Surgeon to the Queen, late Surgeon-General, Bombay Medical Establishment.

DOMVILLE.—On Oct. 21, at Haslar Hospital, William Thomas Domville M.D., C.B., Inspector-General of Hospitals and Fleets, and Honorary Surgeon to the Queen.

JOHNSTON.—On Oct. 17, at Highter, Virginia, co. Cavan, John Alexander Johnston, L.K.Q.C.P.I.

KAVANAGH.—On Oct. 19, at George Street, Limerick, Bernard Kavanagh, M.D., aged 56.

LEONARD.—On Oct. 13, at Clifton, Crosby Leonard, F.R.C.S. Ed., aged 51.

ROGERS.—On Oct. 18, at East Grinstead, John Henry Rogers, M.R.C.P.L., F.R.C.S.E.

FITZGERALD.—On Oct. 15, at Tiverton Villa, Tiverton-on-Avon, Bath, Dudley Lotus Fitzgerald, M.D., M.C., T.C.D., aged 31 years.

GEOGHEGAN.—On Oct. 20, in London, Thomas Grace Geoghegan, third son of Thomas Grace Geoghegan, M.D., late of Dublin.

DONNELLY.—On Oct. 23, at his residence, Auburn, Malahide, co. Dublin, William Donnelly, Esq., C.B., late Registrar-General for Ireland, aged 75 years.

O'CONNOR.—On Oct. 28, at Welshpool, of consumption, Jane, wife of Bernard O'Connor, M.D.

RILEY.—On Oct. 20, Henry Riley, M.R.C.S., late of Stockwell, aged 70.

GENERAL FURNISHING COY

FURNISH ON THE NEWHIRE SYSTEM

Prospectus Post Free

Offices—9 SOUTHAMPTON ST. STRAND.

Over Thirty Wholesale Houses to Select Goods from.

The 'NEW HIRE SYSTEM" is quite distinct from anything yet attempted. Houses, Apartments, Offices, &c., can be furnished throughout without increased yearly expenditure. The Public Press directs the attention of Merchants, Traders, and others to these advantages. Prospectus, with numerous Press Opinions, post-free.

GENERAL FURNISHING COMP., Offices, 9 Southampton St., Strand.

TASTELESS PILLS.—(COX'S PATENT.)

Surgeons and Chemists supplied with an excellent Aperient Pill (the formula for which will be forwarded), covered with a thin non-metallic film, rendering each pill perfectly tasteless, at 1s. a gross. Postage free. They present an elegant pearl-like appearance, and may be kept in the mouth several minutes without taste, yet readily dissolving, even in cold water, in an hour. Any formula dispensed and covered, and samples, with a list of pills, from 500 different forms which are kept in stock, will be forwarded free on application.

Twenty years' success, as proved by unsolicited testimonials from Medical men in almost every town and village in the kingdom, has produced imitations likely to bring a useful invention into disrepute, as a large percentage of the varnished pills made to imitate ours, pass through the stomach unaltered.

The Registrar of Trade Marks has just granted us, after three months' publicity, the Trade Mark of which the above is a facsimile, thus officially recognising our claim as the "ORIGINAL MAKERS OF TASTELESS PILLS." All packages sent out from this date will bear this mark—

ARTHUR H. COX and CO., Tasteless Pill Manufacturers, Brighton.

DINNEFORD'S FLUID MAGNESIA.

IRISH POOR-LAW INTELLIGENCE.

IRISH MEDICAL ASSOCIATION.

REMUNERATION OF MEDICAL OFFICERS OF HEALTH.

The following letters have been sent by the Irish Medical Association to the Local Government Board :—

Royal College of Surgeons, Dublin,
Sept. 17th, 1879.

To the Secretary, Local Government Board.

Sir,—The Council of the Irish Medical Association having learned that the Local Government Board have issued a circular calling upon the local sanitary authorities to furnish a return showing the amount of salary paid to each dispensary medical officer for his services as medical sanitary officer under the repealed Public Health (Ireland) Act, 1874, and also the amount of salary proposed to be given to each medical officer of health under the new Public Health Act, I am directed by the Council to express their decided opinion that unless the medical officers of health are awarded salaries commensurate with the duties imposed, it cannot be expected that those duties will be fully and efficiently discharged.

The Council are aware that, for some little time after the passing of the Public Health Act of 1874, considerable zeal was manifested by many of the medical sanitary officers (as proved by the Parliamentary return made to the House of Commons upon the motion of Dr. O'Leary, M.P.), and there can be no doubt that that energy was exercised in expectation that their services would soon be appreciated, and that the salaries appointed—which, as a rule, were utterly disproportionate to the nature and extent of the duties—would thereupon be increased.

However, the medical officers soon found that the scale fixed, as directed by that Act, precluded the possibility of equitable remuneration being allowed for efficient services, and that their interests as medical practitioners were very seriously and prejudicially affected by the faithful discharge of their duties, and in consequence of the evident discouragement shown by the sanitary authorities to anything like efficient service, the result was a marked falling off in the efforts of the medical officers which, eventually, greatly diminished.

Ever since the new Public Health Act was passed, the newly-appointed medical officers of health have been waiting to see how their services would be valued, before entering upon the duties with that ardour which is so essential to the well-being of the public; but in consequence of the small amount of work recently performed by the medical officers, the Council fear the local sanitary authorities may avail themselves of this as a pretext for either not proposing an increase in the amount of the former salary, or even possibly of suggesting that it shoud be diminished, though it is inconceivable that they could fall into the error of supposing that the amount of work which due regard to the public health requires to be done is insignificant.

The Council confidently expect that the Local Government Board will not confirm the allotment of any salary to a medical officer of health which is not equitable remuneration for efficient service; and if this expectation be realised, there will be no excuse for omission to discharge the duties imposed.

The Council observe that, by the new Act, and also by the recently issued sanitary orders, additional duties have been assigned to the medical officers, which it is expected will not be overlooked as entitling them to still further remuneration.

I am directed to remark that unless, and until, reasonable and equitable remuneration is allowed to the medical officers of health, it is futile to imagine that the provisions of the Public Health Act can come into effectual operation; and further, that the past work done by those officers cannot be considered to indicate the amount of remuneration that should now be allowed, but that, on the contrary, the amount of the salary will, to a great extent, regulate not only the manner in which the duties will be performed, but also the extent of them which will be voluntarily undertaken; and in the absence of any provision for supervision, this appears to be a very important consideration.

As the delay in fixing the salaries to be paid under the new Act did not result from any fault or omission on the part of the medical officers of health, or of the Irish Medical Association, as the representative body of the profession in Ireland, the Council expect that the new salaries will be paid from the date of the commencement of the new Act.

The Council, also, as a body ever mindful of the public interests, trust that an assurance will be given to the medical officers of health that the amount of their salaries will be subject to reconsideration from time to time; zealous and efficient services, as well as the extent of them, being duly recognised, as the justice of such an arrangement is beyond question.

The repealed Act was authoritatively alleged to be "merely a *tentative* measure;" but as the new Act is an *amending* one, it cannot be so considered. It is, therefore, to be assumed that its provisions are meant to be carried out thoroughly, and that none of them are intended to be inoperative; but it cannot be supposed that Parliament, in compelling the dispensary medical officers, without option of refusal, to be the medical officers of health, meant or intended that their services should not be fully and adequately remunerated; indeed, the justice of the claims of the medical officers to more liberal remuneration than hitherto allowed was admitted, not only by the Government, but also by Parliament, as evidenced by the withdrawal of the fixed scale.

To the Local Government Board, therefore, the Council earnestly commend the consideration of this very im-

Digitized by Google

portant subject in all its bearings, it being but reasonable to expect that the work done will only be proportionate to the salaries paid; and as the success of the measure depends chiefly upon the exertions of the medical officers of health the responsibilities of another failure in this direction will, therefore, to a great extent, rest upon the action in this matter which the Local Government Board may decide upon adopting—the question of the amount of success to be obtained resolving itself into one of proportion between work and payment.

The Council, though most anxious to facilitate and ensure the complete and successful operation of the provisions of the new Act, nevertheless cannot approve of supporting any arrangement which, whilst compelling the medical officers of health to hold office and discharge onerous and important public duties, would not afford them adequate remuneration; and in this view, they feel confident they will meet with the hearty support of Parliament, the public, and the medical profession.

I am, sir, your obedient servant,

JOHN WILLIAM MOORE, M.D.,
Hon. Sec. to the Council.

40 Fitzwilliam Square, West,
Dublin.

Irish Medical Association,
Royal College of Surgeons,
7th October, 1879.

To the Secretary, Local Government Board.

SIR,—I am directed by the Council of the Irish Medical Association to acknowledge the receipt of your letter (No. 19,872—Miscellaneous) of the 19th September, with reference to the salaries of the medical officers of health, under the Public Health Act, 1878.

The Council observe—as stated in your letter—that the Local Government Board are at present in communication with the Commissioners of the Treasury relative to the amount of the new salaries of the medical officers of health, and the proportion between any existing salary and the addition thereto, and interpret the terms of your letter as conveying that the Local Government Board are in communication with the Commissioners of the Treasury respecting a *general maximal scale* of payments for all medical officers of health in Ireland and the ratio which the salaries of such officers might bear to those of the dispensary medical officers as such. If this interpretation of your letter be correct, the Council must respectfully dissent from such reading of the 11th section of the Act; and I am desired to express their decided opinion that the Public Health Act of 1878 does not empower the Treasury or any other authority to fix a *general scale* or ratio of remuneration, or to impose any maximal limit whatever upon the discretion of the sanitary authorities save that which the Local Government Board are authorised to impose when called upon to sanction the proposed salary of each individual officer, whose case shall be separately considered. In confirmation of this opinion, the Council would direct the attention of the Local Government Board to the fact that whereas the 10th section of the Act of 1874 empowered the Commissioners of the Treasury to approve "a scale" under which the medical sanitary officers' salaries were to be regulated, the 11th section of the Act of 1878 omits this restriction, and speaks distinctly in the singular number of "*any* new salary and the proportion between *any* existing salary and the addition thereto." The omission of the scale was a deliberate amendment of the Act of 1874, made upon the representation of the Irish Medical Association, when the Bill of 1878 was before the Select Committee of the House of Commons. That representation was made because the Council felt, as they still most strongly feel, that the fixing of a limit of salary, which could not be exceeded, was tantamount to an intimation to the sanitary authorities of Ireland that the services of the medical officers were not to be requited in proportion to their extent and their nature; and, further, that as there is no relation whatever between the sanitary work and the dispensary medical work of any given district, the dependence of the amount of the salary of the medical officer of health upon that of his salary as dispensary medical officer is, therefore, neither just nor expedient. The Council desire also to remind the Local Government Board that in thickly-populated urban districts especially, the sanitary work prescribed for a medical officer of health would scarcely be adequately repaid by a salary equivalent in amount to the salary and emoluments of a dispensary medical officer.

In view of these facts, I am desired to express the opinion of the Council that, under the terms of the 11th section of the Act of 1878, the Local Government Board are required to consider separately the salary proposed to be given to each individual medical officer of health by the sanitary authority of the district; and, in so doing, to have due regard to the extent and population of the district of such officer, as well as to the nature of the duty with which he is invested, and afterwards to submit the additional salary so proposed for the approval of the Commissioners of Her Majesty's Treasury. The Council conceive that the application of any fixed general scale or ratio in the estimation of such salaries would be at variance to the wording and intention of the Act, as well as a direct violation of the assurance of the official representatives of the Irish Executive that each case would be separately dealt with according to its merits.

Your obedient servant,

JOHN WILLIAM MOORE, M.D.,
Hon. Sec. to the Council.

NEGLECTED LUNATICS (IRELAND).

THE following is the Bill presented to the House of Lords by Lord O'Hagan at the close of last session, being "An Act to extend to Ireland the provisions of English Law as to neglected Lunatics."

Whereas it is expedient to extend the provisions of English law as to neglected lunatics to Ireland,

Be it therefore enacted:

1. The provisions of sections 66 to 68, both inclusive, and of sections 70 to 72 both inclusive, and of sections 78 and 81 of the Act 16 and 17 Victoria, chapter 97, entitled "An Act to consolidate and amend the Laws for the provision and regulation of lunatic asylums for counties and boroughs, and for the maintenance and care of pauper lunatics," shall, subject to the changes next hereinafter mentioned, be extended to Ireland.

2. In applying the provisions of the said sections to Ireland, the following changes shall be observed:

(1) The quarterly list of lunatics reported on by the medical officer of a dispensary district shall, in Ireland, be sent to the inspectors of lunatic asylums, Dublin Castle, and to the resident medical superintendent of district lunatic asylum or asylums within the district of which the dispensary district of such officer is in whole or in part situate.

(2) The sub-inspector, head constable, or other officer in charge of any police district or sub-district shall discharge the duty imposed by said sections upon the constable of a place, and such district or sub-district shall be deemed to be a place for the purposes of said Act and this Act.

(3) Relieving officers acting under the Poor-laws in Ireland shall discharge in respect of their respective districts the duties imposed by said sections on relieving officers of parishes in England.

(4) Governors of district lunatic asylums in Ireland shall exercise the power of checking the issue of orders to hospitals or licensed houses vested by said sections in visitors of asylums in England.

Digitized by Google

(5) Two governors of a district lunatic asylum in Ireland may exercise the power vested by said sections in two visitors of an asylum to discharge a lunatic on the undertaking of a relative or friend that he shall no longer be chargeable, and shall be taken care of.

(6) Documents required by said Act to be sent to the Poor Law Board in England, shall in Ireland be sent to the Local Government Board for Ireland.

3. The provisions of the fourteenth section of the Lunatic Asylums (Ireland) Act, 1875, as to the remuneration of medical officers and payment of other reasonable expenses in and about examinations under that Act, shall extend to and apply to examinations, inquiries, and reports under this Act, and any justice or justices causing any person to be examined under this Act may make a like order, and the money so ordered shall be paid in like manner as orders made and moneys paid under that section.

4. When the destitution of any poor person is caused by his being temporarily disabled from labour by reason of mental defect or from the mental infirmity of any person dependent upon him for support, it shall be lawful for the guardians of the poor to relieve such poor person being destitute as aforesaid either in the workhouse or out of the workhouse, as to them shall appear fitting and expedient in each individual case, and for the purpose of the visitation required by this Act such dependent person, though not directly relieved, thall be deemed a pauper lunatic.

5. Where the net amount or the net estimated value of the property of a lunatic is so small as to entitle the Lord Chancellor entrusted with the care of lunatics under the Queen's Sign Manual to exempt such property from fees or per-centage under the Lunacy Regulation (Ireland) Act, 1871, the Judge of a Civil Bills Court in Ireland may, so long as not restrained from doing so by any general order or by any special order in a particular case of the Lord Chancellor entrusted as aforesaid, have and exercise all the power and authority of the Lord Chancellor entrusted as aforesaid over the persons and property of lunatics possessed of such small property who reside within his jurisdiction, and he shall be entitled to the assistance of the officers of his court in the same manner as they are now required to assist in the care of the person and administration of the property of minors of small property under the County Officers and Courts, Ireland, Act, 1877.

6. The governors of district lunatic asylums in Ireland, or a majority of them present at any duly constituted meeting, may deliver over the custody and care of any lunatic to a private person approved of and selected by them upon terms of such periodical payment as such governors shall determine, and upon the undertaking in writing of such person to the satisfaction of such governors that such lunatic shall be properly taken care of and shall be prevented from doing injury to himself or others.

Every lunatic so boarded out shall be subject to the periodical inspection of the medical officer of the dispensary district as one of the pauper lunatics required to be inspected by this Act, and to such further inspection as the governors of the asylum from which he shall be boarded out shall from time to time determine, and shall for all purposes be under the control and care and at the disposal of such governors, and all expenses duly incurred by such governors in respect of any such lunatic shall be defrayed in the same manner and out of same sources in all respects as if such lunatic was a resident in the asylum from which he has been boarded out.

7. This Act may be cited as the Neglected Lunatics (Ireland) Act. 1879.

REDUCTION OF SALARIES OF UNION OFFICERS.

Local Government Board, Dublin, 10th Oct., 1879.

Sir,—The Local Government Board for Ireland have had before them them the minutes of proceedings of the Board of Guardians of the Trim Union for the 27th ultimo containing a resolution requesting their approval of a proposal that the salaries of all the officers of the Union be reduced 10 per cent., and the Local Government Board desire to state that they have given the resolution their careful consideration, and that it appears to them that on the occurrence of any vacancy in an office it would be a legitimate question for the guardians to consider whether the salary of such office might not properly be altered and reduced. But the Board thinks that when a person engages in the services of the guardians at a salary, and that the terms of his appointment are that he should be paid such a salary, it is not reasonable or just to reduce that rate of payment on grounds such as those which now appear to influence the guardians while he satisfactorily discharges the duties which he undertakes to perform. The Board finds, however, that this is the course which the guardians propose to adopt in several instances, and that in the cases of the medical officer of the workhouse, the porter, and one of the nurses, and in the cases of Dr. Rooney, Medical Officer of the Atteboy Dispensary District, Relieving Officers Byrne, Glaman, and Higgins, and the three Midwives of the Union, the guardians wish to reduce the salaries, which are not by any means exorbitant, to a lower rate than that at which those persons were elected. With reference to other officers, whose salaries have been raised after many years' efficient service, the Board are of opinion that it would be ungenerous to deprive them of the advantages so gained while their duties remain unchanged, and that such a proceeding would tend to produce discontent and a feeling of insecurity in regard to their position which would have an injurious effect on the affairs of the union; and it would discourage zeal and attention on the part of the officers in the performance of their duties. The Board observe that in the following instances the persons whose salaries the guardians desire to reduce are—the matron of the workhouse, appointed in the year 1856, and who has accordingly given about twenty-three years service in that capacity; Dr. Trotter, medical officer of the Summerhill Dispensary District, appointed in the year 1860; the clerk of the Union, in 1864; Relieving Officer Tyrrell, in 1865; the matron of the workhouse, in 1866; Dr. Tiate, medical officer of the Enfield Dispensary District in 1868; and one of the workhouse nurses in 1869; and it would certainly appear reasonable that the length of service of these officers should render them deserving of consideration in regard to the continuance of their existing emoluments. It is open to the guardians to propose an alteration of salary in any instance in which there has been a change in the circumstances under which it has been fixed or increased, but for the reasons given above the Board feel it necessary to withhold their sanction to a general reduction of the officers' salaries in the manner proposed, which, while it would effect a saving of less than one farthing in the pound on the valuation of the union, would operate unjustly on several of the persons effected thereby.

By order of the Board,

B. Banks, Secretary.

THE SANITARY STATE OF LIMERICK.

At the meeting of the Limerick Urban Sanitary Board yesterday week, the Mayor (Mr. P. M. O'Gorman), presiding, a complaint was read from the Resident Superintendent Medical Officer of Health, in respect to the sanitary state of Limerick, and the action of the members relative thereto. After some general observations, Dr. Barry wrote:—

"Since the 1st January last 311 cases of zymotic diseases have been reported by the medical officers of health, and no less than 130 persons lost their lives from more or less preventible causes. It has been frequently brought under the notice of the committee that the measures in force for the prevention of the spread of infectious diseases are altogether insufficient. The process of fumiga-

Digitized by Google

tion is imperfectly carried out, and even were it efficiently performed, I declare it to be perfectly valueless as a protective measure so long as the beds and clothing remain without disinfection. Without a disinfecting chamber your committee and officers are powerless to deal with the infectious diseases, and it is sad to consider that every month 35 persons are being stricken down, and 15 lives are being lost through preventible di-ease, while the necessary and most effective means for their safety and protection are being denied them."

Mr. Hastings—The inference to be drawn from that letter of Dr. Barry's is, that if we had a disinfecting chamber no one would die in the city (laughter). Well, now, will any sane person believe Dr. Barry when he makes such a statement?

Alderman Synan—What he meant is this, that if you had a disinfecting chamber those lives would not be lost.

Mr. Hastings—Dr. Barry lays the whole blame on the want of a disinfecting chamber, and the fact of a few rags not being fumigated. What is to be done with the clothes of the doctor who attends a fever patient, or the nurse? This shows that it is all nonsense stating that because you have not a disinfecting chamber there are so many deaths in the city.

Mr. Corbett reminded the Board that a copy of Dr. Barry's report would go on the minutes to be sent to the Local Government Board.

Ald. Myles—I think we would want to get another officer of health instead of Dr. Barry.

Mr. Bernal—I propose that Dr. Barry's letter be referred back to him for re-consideration.

Ald. Myles—Oh, Dr. Barry will re-affirm every word of what he states in his letter.

Mr. Bernal—Well, if he does, we will re-affirm him in another way.

Mr. Hastings—Dr. Barry's letter is an insult to every man of honesty and intelligence in the Corporation.

Mr. Bernal's motion was unanimously agreed to.

INCREASED DUTIES UNDER THE NEW PUBLIC HEALTH ACT.

THE following communication was read at the last meeting of the Armagh Town Commissioners:—

Armagh Dispensary,
Oct. 6, 1879.

GENTLEMEN,—In compliance with your instructions of last board meeting to furnish you with the amount and nature of duties imposed upon me by the Public Health Act of 1878, I beg herewith to submit the same. First, I would point out the duty under the Act of 1874, now more or less repealed. Under it my duty was to inspect and report to your Board, as Urban Sanitary Authority, all cases of nuisance reported to me, and if found on inspection to be a nuisance or injurious to health, then to report same to you, together with such remedy as the case required. Under the Public Health Act of 1878 there are a number of new duties added to my former duties, as now I must *seek out* all causes affecting or threatening to affect the public health. To carry into full effect this one duty will entail continual watchfulness and inspection, every part of the urban district, now enlarged, together with each house therein, which at present numbers over two thousand, must be periodically inspected; this, in addition to, and irrespective of inspections made upon receiving notice from any person who may feel aggrieved by any unsanitary condition of his own or his neighbour's premises, as also upon receipt of complaint of the existence of nuisance by sanitary sub-officer; and lastly, having now to inspect all works done after issue of order by the Sanitary Authority to see that the work has been executed in accordance with the order of your Board, whenever called upon by the executive officer to do so. I may here observe that during the past five months I have served 61 sanitary reports upon the executive officer, which represents 183 visits to different premises throughout the district. Besides these, I have made over 100 inspections on complaints and otherwise, in which the nuisance or cause of complaint was removed without the necessity of reporting to your Board. Further new duties have been imposed upon me under the Lodging House, Common Lodging House, Bakehouse, and Slaughter House Acts, which are now included in the provisions of the Public Health Act of 1878. The inspection required under the Common Lodging House Act will in many cases have to be made at night, or on complaint I may be required to leave my bed at night to inspect under this Act. Finally, in a city like Armagh, to discharge fully and efficiently all the duties imposed upon me by the Act of 1878 will take up all my spare time, and so far as my province goes I am anxious to have this district in as sanitary a condition as it is possible to have it. The importance of this, financially and otherwise, it is unnecessary for me here to dwell upon, as I am sure that each gentleman present is as fully conversant with and alive to it as I am.

I am, gentlemen, your obedient servant,

ROBERT GRAY.

To the Town Commissioners of Armagh.

The Clerk stated that the Local Government Board had written to know whether the Board would appoint Dr. Gray as Medical Officer of Health at the old salary or would they increase it. The only sum the Board paid Dr. Gray was £6 6s. as consulting sanitary officer, and the one-half of that sum was refunded to them from the Local Government Board. Dr. Gray, as sanitary officer, was paid by the Board of Guardians £20 a year, one-half of which was refunded to them.

Carried unanimously, that Dr. Gray be appointed medical officer of health at a salary of £30 per annum, and consulting sanitary officer at the former salary of £6 6s.

MOUNTMELLICK UNION.

READ letter from the Local Government Board in reference to proposed reduction of salaries.

The Board observe that the salaries in Mountmellick union are not excessive, and trust that the guardians will no longer object to the rate of remuneration which the medical officers of the several districts received under the Public Health Act of 1874.

Mr. Vanston asked if the medical officers of health had done anything at all since their appointment under the Public Health Act.

Clerk—Nothing, except reporting some existing nuisances.

Clerk—I would imagine from the reading of the letter that the Local Government Board are inclined to give way to the guardians.—Resolved.

"That we most respectfully beg leave to inform the Local Government Board that the duties connected with the sanitary laws are so light, and the present state of the country so unequal to bear extra taxation, that we still most earnestly hope that the Local Government Board will confirm the adoption of the salaries already proposed; and we herewith forward the number of cases that have been reported in this union for the past five years."

The number of reports were thirty-two.

TO READERS.

THE Editor will feel especially obliged by receiving copies of newspapers which contain any Poor-law or other intelligence of medical interest, in order that he may, if fit, republish it for the benefit of the readers of the *Medical Press*. Although twenty-one of the leading Irish newspapers are received at the Irish office, many things may escape notice which are deserving of attention. Newspapers should be marked, and addressed to Dr. JACOB, at the Dublin office of this paper.

ON CROUP.

By W. H. DAY, M.D.,

Physician to the Samaritan Hospital for Women and Children

Pathology—Nature of the Exudation—Two Varieties of Croup—1. The Mucous or Catarrhal—2. The Fibrous or Inflammatory Symptoms—Course and Progress of Each Form—Morbid Appearances—Clinical Characters of True or Typical Croup—Diagnosis from Diphtheria and Laryngismus — Treatment by the Vapour-Bath and Emetics—Mercury—Aconite—Tracheotomy.

(*Concluded from page* 369.)

Laryngismus stridulus is another disease which is apt to be mistaken for croup; but the following diagnostic points of difference are so broad and clear that in ordinary and well-developed cases it would be inexcusable to confuse them:—

1. Laryngismus usually sets in suddenly with alarming symptoms, and terminates abruptly; in true croup the invasion is less sudden, there has been cough and febrile disturbance for a day or two, and the symptoms, instead of declining, go on increasing in severity.

2. In a typical case of laryngismus the voice is unaffected, and there is no cough; in croup there is both cough and change of voice, and the latter is often weak and feeble from the commencement.

3. In laryngismus there is no expectoration nor any catarrhal sounds in the chest; in croup such symptoms are constantly met with.

4. In laryngismus there is no fever (that is sufficient rise of temperature to deserve the name of fever), and the circulation is undisturbed, except during the paroxysms; in croup the fever runs very high, there is thirst, heat of skin, and quick pulse.

5. Age comes greatly to our aid. Laryngismus is most common in infants during dentition; croup is most frequent between the second and fifth years.

6. Laryngismus is most common among strumous and rickety children, and those who have been ailing and out of health. It is constantly associated with dentition, and over-feeding or improper food; croup often attacks the healthiest and strongest children, and generally arises from exposure to cold winds, or damp—it is far more frequently fatal than laryngismus, which is only exceptionally dangerous.

7. In croup there is not the same immediate violent struggling for breath as in laryngismus, then, too, in laryngismus there is complete recovery between the paroxysms.

8. In laryngismus the condition is one rather of syncope or fainting; the attacks are usually too short to produce permanent lividity from aeration of the blood.

9. In laryngismus death may occur from complete asphyxia; in croup a sudden termination may result from a portion of detached false membrane exciting fatal spasm of the larynx; but death usually happens from interrupted respiration and circulation through the lungs, with gradual depression of the vital powers.

10. In a case of laryngismus the inspiratory effort is temporarily affected, arrested, or even stopped entirely; whilst in croup the embarrassed breathing is permanent, and expiration as well as inspiration are both involved.

11. The treatment of the two affections is diametrically opposed; the remedies that would relieve the one would aggravate the other.

So much for the distinctions of laryngismus from croup. But I must not dismiss this question of diagnosis without admitting that there are complicated or mixed cases, attended with wheezing and catarrhal symptoms, where a degree of catarrhal inflammation is mixed up with the spasmodic affection. These are the cases which more nearly resemble true croup, cases of modified laryngismus happening to young children, where we have no such precise landmarks as those I have attempted to define. They commence with slight catarrh (*catarrhal laryngitis*), hoarse and noisy cough a day or two before the characteristic crowing inspiration, and they sometimes precede an attack of pneumonia or measles. It is cases of this kind, attended

Digitized by Google

with a croupy cough, which are apt to deceive and mislead us; there is, in fact, some swelling and inflammatory action of the larynx and vocal cords added to the original spasmodic affection. The presence of cough with wheezing and dyspnœa might induce even a practised observer to think he was dealing with an ordinary case of croup, but as it advances he is able to satisfy himself that genuine spasm is at the root of the evil. In the simplest forms of catarrh in some young children the voice is hoarse and the cough barking. To such an extent does this prevail, that a diagnosis is not invariably easy at the beginning of an illness. The mucous membrane of the larynx is highly irritable and sensitive, and readily becomes inflamed and swollen on exposure to cold air. This is probably the condition that is present in those cases of laryngismus attended with incessant and croupy cough. Though we must not expect to find the same pathological change, or the same catalogue of symptoms, in all cases of laryngismus, still viewing these cases from what point of view we may, I can seldom imagine any real difficulty to obscure the diagnosis of these two affections, if we bear in mind that in genuine laryngismus the larynx and trachea are free from inflammation, that the attacks are sudden and temporary, that there is no cough and no fever; all which symptoms are the accompaniments of croup.

Of the forms of croup there is, firstly, the catarrhal croup, a mild class of cases of frequent occurrence which rarely places the life of the patient in imminent danger. It may come on in the night, with some heat of skin, frequent husky cough, quick pulse, and flushed face; and for a few hours the symptoms are severe and alarming to the parents; even the medical attendant is doubtful about the issue of the case; but after a dose of calomel and the free action of an emetic (the room being kept moist, and its temperature high), the symptoms soon decline, and the child is himself again, with the exception of being a little prostrate and pallid.

Again, there is also another class of cases, the *Fibrinous Croup* or *Tracheitis*, happening to healthy children, which comes on suddenly and is attended throughout with danger. These cases are rapid in their onset, and are quickly fatal.

The tendency to a recurrence of croup in some children is a favourable sign so far as regards its severity—such cases seldom terminate fatally, for these are of the *catarrhal* form. If we are told that the child has had one or two previous attacks, we may generally regard the case as satisfactory. Such cases stop short of actual exudation, and spasm also plays an important part in the production of the symptoms. The mucous membrane of the larynx and trachea is in a state of inflammatory excitement, and the vessels are full and congested. Prompt treatment rapidly unloads the distended vessels and encourages expectoration. Intelligent mothers whose children are so attacked come at last to view the symptoms with little or no anxiety, feeling confident that a good fire, with a steaming kettle in the room, a brisk emetic, and hot sponges kept constantly applied to the throat will soon bring the child round. The lesson to be learnt here, as in every other variety of croup, is to lose no time, for success in treatment depends on meeting the symptoms with promptitude. Above all, care must be taken not to confound these cases with laryngismus, for in the one there is fever and persistent difficult breathing; whilst in the other there is no fever, and the breathing between the paroxysms is calm and tranquil.

Treatment.—Careful study of the disease has done much to instruct the medical attendant, and the knowledge that no time is to be lost is so commonly spread, that before we are summoned to give relief some useful measures have been tried, and thus many lives are saved which neglect would have rendered hopeless; yet for all this it is estimated, according to the returns of the Registrar-General, that about 6,000 children die annually of croup in the United Kingdom, a mortality which ought to enlighten us as to its fatal nature, and induce us to study the best method of dealing with it.

I have observed nothing of late years to induce me materially to alter my opinion from the following conclusions at which I arrived in 1863 (*Brit. Med. Journ.*, May 30). The temperature of the room should not be lower than 65°.

1. The vapour-bath is indispensable in the treatment of croup, and should be used at the commencement in every case, and continued unremittingly until all fear of a relapse has departed.

2. All cases of croup are invariably relieved by the vapour-bath, especially if the tracheal membrane is dry; when it is moist there might be fear of causing too much depression.

3. The earlier that a case comes under treatment, the greater the probability of a successful termination, because it is then possible to prevent the tracheal secretion becoming organised.

4. The most trying difficulty we have to contend with in the management of croup in the catarrhal form is a relapse, because with it comes exhaustion; and the weaker the patient, the less will be the chance of recovery.

5. Tartarised antimony is our sheet-anchor as a medicinal agent; not so much from any specific effect it exerts on the tracheal membrane, as from its certainty in effecting free and speedy vomiting.

6. Tartarised antimony should, however, be mainly given for the purpose of procuring vomiting; that failing, it is comparatively useless, because, if continued in small doses at intervals, its depressing effect is too great.

7. When the emetic has fully operated, if there be much febrile excitement and disordered primæ viæ, which aggravate the laryngeal symptoms, a grain of calomel every four hours, or one full dose for the purpose of emptying the bowels and controlling the fever, will be found necessary. In the fibrinous form, when there is violent and acute inflammation, with a firm, hard pulse, and a full reserve of strength, two or three leeches may be applied over the thyroid cartilage, and bleeding can easily be arrested by pressure with the finger, and if need be, with cotton wool; then mercury may prove a valuable addition to the antimonial treatment. Some of my cases improved from the moment the mercury affected the bowels, the fever diminishing, and the expectoration of the false membrane being promoted. When employed in small doses at regular intervals it would appear to diminish the cohesive attachment to the mucous membrane, and to render the lymph less fibrinous and more readily absorbed.

8. When in a case of croup, seen at an early stage, and satisfactorily progressing, forty-eight hours have elapsed, we may generally augur a favourable termination; and we should then begin, if not before, to support our patients with good beef-tea, milk and arrowroot, and (it may be) a little wine and water.

If after vomiting the temperature remains high, and especially when the bowels have acted freely, minim doses of aconite every two or three hours are of great service in inflammatory croup. This keeps up a gentle diaphoretic action on the skin, diminishes tension of the pulse, and controls vascular excitement in a very striking manner. At this stage it comes in well, because antimony should not be long continued in any of the diseases of children, and it certainly ought not to be in this disorder.

On the question of tracheotomy, I am inclined to think we may urge a great deal in its favour. When the respiration is so involved as to produce almost complete unconsciousness, swelling and distension of the features, and lividity of the lips (convulsive efforts that indicate approaching suffocation), we should cling to the chance it holds out. When all remedies have failed to improve the patient's condition, and death is near at hand, shall we let the patient die without giving him the chance of life which an operation affords? Though it be a slender one, it is not to be rejected at a time when medical treatment has signally failed and every hour finds the patient worse.

In most of the cases of tracheotomy that have fallen under my notice, I have almost invariably observed an improvement for a time in the respiration, and the fact that a few days have been gained when death must have ter-

Digitized by Google

minated in as many hours is a great point in favour of the operation, and for not delaying it too long. If tracheotomy is to succeed, it must be done before the strength is quite exhausted and asphyxia has thoroughly set in.

M. E. Dudon, of the Hôpital St. Andrè, Bordeaux, performed the operation in twelve cases, with six recoveries; and he is of opinion that could he have performed the operation earlier in some of the cases he would have had more recoveries. When medical means have failed, and the larynx is invaded by false membranes which cannot be got rid of by vomiting or other means, M. Dudon thinks tracheotomy justifiable. (a)

It should be our earnest endeavour to recognise whether we are dealing with the catarrhal or the fibrinous form of croup. If we are convinced it is the fibrinous form, then it must be at the discretion of the surgeon whether or not the symptoms are such as to lead him to expect that resolution will take place. If not, tracheotomy should be performed at once, as its postponement would render a successful issue less probable.

Tracheotomy in itself is not a dangerous operation, but if it be delayed till the lining membrane of the larynx and trachea are covered with false membrane, extending as far as the primary divisions of the bronchi, and the constitutional symptoms are becoming severe, the chances of its success are materially diminished.

This we often see when tracheotomy has been performed at too late a period of the disease, and the operation has the discredit of the fatal result.

When extensive, or loose, or purulent portions of false membrane occupy the primary branches of the bronchi, and extend to and choke up the smaller or minute bronchi, the operation cannot be expected to succeed. It is performed too frequently as a last resource, when the respiration is too impeded and embarrassed and exhaustion has advanced too far. Under a combination of asphyxia and asthenia the child sinks.

Now what are the dangers of tracheotomy? There are no doubt some; but are they of sufficient importance to contra-indicate an operation?

Many successful cases have been recorded from time to time. If the symptoms are urgent, I would strongly advocate its adoption; for when death is threatening, and cannot otherwise be far distant, an incision in the trachea has been attended with the escape of the fibrinous exudation through the wound which no coughing or vomiting could have removed. Immediate improvement in the symptoms has set in, followed by complete recovery.

Though the unsuccessful cases usually terminate in twenty-four hours from exhaustion or loss of blood, life has been prolonged from one to thirty days after the operation, and the mode of death has, in some cases, been rendered comparatively easy.

In those children who survive the operation for some days, bronchitis, pneumonia, broncho-pneumonia, and convulsions are the most frequent causes of death. A tendency to pulmonary excitement already exists, and indeed the operation itself is calculated to originate it. Tracheotomy is a very successful operation when performed for the relief of chronic laryngeal diseases, or for the removal of foreign bodies from the air passages. But it is significant that this operation does not generally yield satisfactory results when undertaken in cases of œdema of the glottis, occurring in children who have sucked boiling water from the spouts of kettles. After this grave accident, lung affections very often supervene, from the inspiration of scalding vapour simultaneously with the boiling fluid. Tracheotomy aggravates the pulmonary complication; yet it must be done, on account of the œdema of the glottis. Very similar considerations apply to croup. In some cases where children have been saved from the prospect of immediate death by tracheotomy, and the canula cannot be removed with safety for a moment without the danger of asphyxia, the chances of ultimate recovery are very slight. The little patient having rallied from the operation, goes on satisfactorily for some days, when it becomes restless and feverish at night, with a hot skin and a quick pulse. If we auscultate the chest, we find extensive bronchitis, and perhaps some pneumonia. No more sputa are evacuated through the canula, and the child soon becomes convulsed, or dies in a comatose condition. There may be no accumulation of false membrane in the larynx; but if the glottis is nearly closed by swelling and œdema, and the mucous membrane injected and vascular, the extension of inflammation down the trachea and bronchi into the tissue of the lung constituting lobular pneumonia is almost certain to ensue. If the case goes on, abscess of a portion of the lung, pleurisy, or empyema are among the morbid changes discovered after death. From all I have been able to ascertain, the operation of tracheotomy is less likely to succeed in children under two years of age than in those above it. The trachea is small and undeveloped, it is not so easily reached as in older children, and hæmorrhage may occur, but a competent surgeon may readily overcome it. Yet in the face of these difficultles, infants have survived the operation; but the greatest number of recoveries after the operation has occurred between the ages of five and six years.

It has been alleged that the direct admission of the air to the lungs without having previously passed through the mouth and nasal passages is attended with real danger, and that congestion of the lungs is another danger induced by the operation. But seeing that the temperature of the room can be raised to any extent, and that appliances for the supply of warm moist air are to be procured, congestion of the lungs from this cause alone ought not to occur.

(a) *Lancet*, July 20th, 1872.

SANITARY SCIENCE AND PREVENTIVE MEDICINE. (a)

By ALFRED CARPENTER, M.D. Lond.,
President of the Medicine Section of the Sanitary Institute of Great Britain and Ireland.

Dr. Carpenter, after alluding to the age of the subject, said its newness as a science pressed the necessity for strict investigation into the causes of disease, and declared that nearly all the diseases which are fatal to young people were amenable to prophylactic measures, capable of diminution in their fatal effects; and he considered it to be probable that many might be altogether prevented by a right application of knowledge, so that pneumonia, bronchitis, mesenteric disease, and other causes of death would cease to be common, as well as those deaths produced by enthetic disease. He urged the necessity for an improvement in the mode of registering deaths, in order to show the origin of the diseases ending fatally, some being, in fact, by enthetic disease, or by continuous indulgence in intoxicating drinks. A very large portion of the diseases which affected particular organs, and in which the first starting point was a kind of fatty degeneration of tissue, had their origin in the habitual use of intoxicating liquors. The Registrar-General's returns, as at present constituted, gave but little real insight into the habits of the people. Then, too, he said, it was necessary for every family to have some knowledge of their hereditary tendencies before they could have the best measures for the removal of such tendencies from their own persons. The prevailing diathesis and the hybrids which arise from intermarriage must be recognised and treated accordingly if good health was to be obtained. Treatment must not be limited to those times at which there was a local manifestation of disease. Prophylactic measures were necessary in apparent health as well as during actual illness. It was a mistake to suppose that the date at which a given illness had apparently commenced was that at which it

(a) Read before the Sanitary Congress at Croydon, 22nd October, 1879.

Digitized by Google

really began, and he pressed the point that people should know their own tendencies, so as to counteract them in themselves and families. He impressed upon his audience that each type of disease required a different kind of pabulum for its production, just as wheat grew better in some soils than in others; while there were soils in which it would not grow at all, but where water-grasses flourished. So we had searlatina abounding among one set of people, typhoid fever among another, and dysentery a third. There was nothing more curious or out of the way in the rise and fall of epidemics than there was in the abundance or scarcity of certain forms of vegetable life according as the season was dry or moist, or hot or cold, and according as the material required for its nourishment was abundant or the contrary.

Urging as the basis of sanitary work the particulate nature of contagia, and that the particles upon which disease depended for its development were germs connected with the vegetable kingdom of the algæ rather than fungi; and he adopted Cohn's classification as to their position. He regarded the rise of temperature in disease among animals as caused by the multiplication of vegetable growth in the blood; whilst the diseases which were incident to vegetation he ascribed to the fungi—the latter having aerial, the former an aquatic fructification—and he especially drew attention to the fact that each class has an evanescent and a persistent form of fructification. That attention was especially required to the latter form if the re-appearance of disease was to be prevented; and he illustrated these points by reference to animal and vegetable pathology.

He then dealt at length with the pathology of zymotic diseases, and with the problem of the often discussed germ theory of disease. He then went on to say :—"We cannot look upon the diseases of organic nature with perfect complacency; we must not consider that they only affect our pockets and not our health. Before English people can have that perfect health which is the birthright of every child born into the world, it will be necessary to alter our plans regarding the breeding of cattle and the methods of housing and feeding them. Our domestic animals fall an easy prey to every kind of epidemic. For all sanitary law is, as a rule, ignored by the farmer. Knowing something of the customs of the country, I was not surprised when I heard an inspector from the Metropolitan Meat Market declare upon oath, in the Croydon Police Court, that 80 per cent. of the meat which was sent to the London market was the subject of tubercular disease, and that to exclude it from the market would leave London without a meat supply. The foul air in which animals are often kept, the foul water with which they are supplied, and the musty food which is given them to eat, easily account for the readiness with which they fall victims to every kind of malady. The deaths among cows during the calving process are very great and is one of the reasons why meat continues dear. Such deaths ought not to occur at all. We cannot remove disease from our midst or reduce our death-rate much below 17 in the 1,000 until we can insure a more healthy progeny among our domestic animals. To do this something more is necessary than to insist upon measures for the prevention of disease among men." He proceeded at length to urge the value of ventilation for the remedy for many sanitary evils. He contended that currents of air must be established to lessen the quantity of carbonic dioxide to something less than 450 parts in a million; and by introducing a fresh supply of oxygen, the albuminoid matters which living creatures give out might be altered in their chemical characters. Motion of both air and water was a principal law of sanitary work. Stagnant air in the house-drains of Croydon produced more or less evil in almost avery house in the place until their local senators were convinced of the evil. It was in Croydon that the law for ventilating sewers was first put into operation by a local authority. But the local authority were then in advance of the intelligence of the people; and, although the command was issued, the work was not generally done until much more proof of its necessity was afforded. Now, the ventilation of the sewer and of the house-drain was required by the law of the land, but it was not nearly so general as it should be. Assuming that sewers were necessities in a thickly-peopled neighbourhood, they must not be allowed to ventilate into houses. There must not be any communication directly between sewer and the interior of the house. There was no occasion for any departure from the law, and it should never be allowed in practice. There was another danger which arose from sewers if they were not constructed of impervious materials; brick sewers were open to great objection when they passed through pervious soil in close proximity to houses.

Unless they were very freely and efficiently ventilated, they contaminated the air of a sub-soil of a town until it became a perfect hotbed of mischief. This was a frequent cause for the continuance of endemic diseases in districts in which the water-line rose and fell at distinct intervals. He gave some practical observations, which will be studied with interest by all local authorities upon whom sanitary questions are being pressed now, in the following remarks : "A local authority, in providing for the utilisation of sewage by irrigation, must be prepared to pay the difference in value between the price of the land and its ordinary agricultural worth. One penny in the pound on each rate, or at the most 3d. for the year, ought to be amply sufficient for this purpose, as well as for the payment of interest on money sunk in unexhausted improvements. The Beddington Farm, which has now been in operation more or less for 20 years, costs more than this; but if the farm had to be formed now, the experience which has been gained (if it was available, and if members of a local board could condescend to think that anybody else knew what was wanted better than themselves) would enable the Board to carry out the work at a much less cost. I say if that experience were available; but, unfortunately, local self-government tends to scatter experience to the winds. Those works, upon which considerable sums of money have been sunk in as yet unexhausted improvements, are not followed up because present managers do not know anything about them. Then, although sewage should be conveyed to the soil as rapidly as posible, rainfall should go into the river. It is a wrong thing to conduct rainfall into sewers, as by this means a sewage farm is swamped with unnecessary water. Not that storm water from the streets of London should be sent into the Thames, or the washings of thickly-peopled cities at once into the waterway, but ordinary surface water should be strictly excluded; and, when possible, the rain-water from house-roofs should go to the water-courses. This is a good reason for excluding sewers from thinly-peopled districts; ordinary sewers will only drain the sub-soil, empty the water-courses, and dry up the smaller source of our rivers, and produce as much evil in the subsoil as cess-pools now do. They are serious blunders too often perpetrated for the personal benefit of private individuals. A great law of sanitary work is for sewer and water services to be decidedly separated, so that no interchange either of liquid or gases should be possible. It was shown not long since that just where a water-pipe passed over a sewer, there the pipe was defective, and as a consequence a serious epidemic arose. Sewage soon decomposes iron, and if water-pipes were allowed to lie in sewers, and to occupy portions of cespits on the road-side, or to be in communication at those points at which water is delivered into a house, and slops and sewage removed, there can be no real safety for the people. I am sometimes astounded when I hear men who put themselves forward as sanitary authorities utterly ignore this fundamental law. Another law is that the individual house is the unit of sanitary work; that it is in each houge, and it is with each individual that the first action must be taken to diminish the power of *z* to grow and reproduce its kind; while, should *z* be introduced, it is the individual case which is the unit of repressed. But all these canon laws have their foundation upon the particular nature of the contagia, and it is by bearing this one

Digitized by Google

fact in mind that sanitary work can produce sufficient fruit to be successful.

The sum of his conclusions were that the primary sanitary laws are—

1st. The particulate nature of contagia.

2nd. The necessity for motion of sewage and all excreta.

3rd. That there must be no direct communication between the sewers and the interior of the house.

4th. That sewers must be freely ventilated.

5th. That sewage must be utilised the moment motion ceases.

6th. That sewers and water services must be completely separated, so that interchange should be absolutely impossible.

7th. The the individual house is the unit of sanitary work.

8th. That the individual case is the unit of suppression.

Besides these eight laws there were nine conclusions which the reader had arrived at from personal experience on the Beddington sewage farm.

Clinical Records.

ST. BARTHOLOMEW'S HOSPITAL.

Sub-diaphragmatic Abscess, with Tumour, consisting of Left Lobe of Liver, and circumscribed Peritoneal Thickening, apparently derived from Cicatrix of an old Perforating Ulcer of Stomach—Death by Lung Gangrene, and Perforation of Abscess through into Left Pleura.

Under the care of DR. SOUTHEY,
Physician and Lecturer to the Hospital.

ELIZA M., æt. 50, married, and mother of several healthy children; a nervous, sallow, emaciated-looking woman, with black hair, rather over-grizzled for her years, was admitted into No. 19 bed of back ward of Faith, May 28, 1878, complaining of pain in her epigastrium and left hypochondrium, and of vomiting. The pain she described as of a sharp cutting nature, not constant, but coming on at various times in the course of the day, easily provoked by any sudden movement or pressure in the region of her stomach. Here a knobby-hard mass was to be felt, about the size of a hen's egg. The tumour could be traced extending downwards towards the umbilicus, but was quickly lost upwards, beneath the arch of the thorax and ribs in the left hypochondrium, but the manubrium sterni was not bulged forward as if by any considerable mass beneath it.

Tumour was dull to percussion, lobulated to feel, or consisted of an irregular-shaped lump; it exhibited well-marked pulsation, this being communicated to it apparently by large arteries passing behind or near it. The tumour did not expand in a manner at all suggestive of an aneurismal sac; it gave an up and down tilt to a stethoscope held over it. It was further very tender to pressure, and the abdominal muscles were instinctively thrown into contraction to protect the tender parts beneath them, and prevented any attempts to explore its limits more closely. Skin of abdomen much pigmented from hot applications to it. Abdomen itself flat.

History.—She stated that for the last two months she had been entirely prostrated, with complete loss of appetite, occasional vomiting, and the pains above described. For five or six weeks she had had no inclination to try anything solid in food, but did not think this would necessarily increase her pain, or be followed by sickness. She had subsisted recently chiefly upon milk and beef-tea; bowels had been constipated; urine scanty, and high-coloured; sp. g. 1025, acid, no albumen or sugar. She said she had wasted a great deal, and sweated much. Told us the pain was at times so intense as to make her burst into a cold sweat. She had been obliged to take sleeping draughts latterly, and after them had only slept indifferently. Further and later inquiry elicited that her illness dated further back than two months. She had had dyspeptic symptoms for some years, and referred her troubles to a blow in the region of her stomach, which she had received twelve years previously from the shaft of a hand-truck that she was pushing up a hill. Late that same day she vomited for the first time a large quantity of black blood, and since that time she has vomited and passed blood at stool on several occasions. The last time she remembered this hæmatemesis distinctly, was two years ago, when certainly more blood was passed at stool than vomited, but she then had very severe pain in her stomach; was completely laid up for some days, and was unable to take any solid food for some time, by reason of pain thus provoked. The blood vomited was partly congealed, that passed at stool, for four days after it was dark-coloured. Whenever on previous occasions she had vomited or passed blood at stool, she had had pain after eating solid food.

Previous Health.—Had rheumatic fever when a girl, and was laid up for four months with it. Her father died of phthisis. No history of cancer in her family that she knew of.

Physical Examination.—Skin hot, clammy; temp. 99; resp. 30; pulse, small, feeble, regular, 108; extreme muscular debility, she being unable to lift much less move herself.

Thorax.—Thin, bony, long, shallow; resonance boxy generally, anteriorly, and at upper parts posteriorly. Respiration sounds loud and coarse; no moist sounds unable to examine bases posteriorly, for she was too feeble to sit up.

Heart.—No increased precardial dulness; sounds feeble; glands of groin and axilla enlarged; epigastrium, as already described above, filled with tumour; abdomen empty and shrunken.

Treatment.—Ordered an enema, simple; milk and sago; milk and lime water; ext. opii., gr. j., formâ pils. n. et. m. Carslbad salts if required each morning.

Course and Progress.—Note of May 30.—Although she has adhered strictly to her milk diet, she has vomited three times to-day, but no blood; nothing but milk and mucus. She remains extremely feeble. Temp. 98·8; resp. 30; pulse 100.

Morning of June 7th she coughed up some quantity of extremely fœtid purulent matter. Temp. 100; resp. 36; pulse 112.

June 8th.—Cough very troublesome. Breath has the fœtid odour of gangrene of the lung. Copious fœtid expectoration. Abundant moist sounds in left lateral region, with dulness on percussion. She was too feeble to examine much. Respiratory sounds elsewhere coarse and compensative.

10th.—Passed about a pint of bright red blood per anum.

She gradually sank and died on the morning of the 14th, her temperature having risen up to 100·6; resp. 40; pulse 136, two days before her end. She continued to take fluid nourishment without vomiting to the end, as well as her opium, and appeared to suffer little or no pain.

Terebene inhalations relieved her fœtor considerably, and chlorinate of lime in the spittoon was found to make the sputum least disagreeable to the ward.

Post-Mortem Book, p. 306.—Post-mortem 26 hours after death. Body much wasted; rigor persistent; both pleuræ adherent. Pericardium and heart natural. Upon opening abdomen a large irregularly circumscribed abscess cavity was discovered between the upper surface of left lobe of the liver and the diaphragm, and between the lower part of liver and upper part of stomach. The abscess was strictly bounded below by the suspensory ligament of liver. Sinuses led in several directions, backwards and downwards, between the diaphragm and liver and stomach, and the diaphragm was perforated through into the left pleura by

Digitized by Google

several such shreddy openings. The base of the left lung was broken down into a foul gangrenous abscess, and above the sloughing part were a few scattered abscesses; and in lower part of upper lobe another small abscess.

Right lung œdematous and emphysematous. Spleen firmly adherent to surrounding parts, its upper part forming a boundary wall of an abscess sinus; its substance not involved. Substance of liver not implicated; its structure normal. No dilatation of gall ducts. No gall stones.

Stomach orifices normal; but at posterior aspect at usual site in lower curvature upon peritoneal surface was seen the old cicatrix of a round ulcer, with thin transparent floor about the size of a sixpence. One sinus from the abscess led direct down to this cicatrix, and although no perforation in the stomach was apparent, it was plain that the abscess had derived origin from the old healed stomach ulcer; and fluids from the stomach might well have oozed through the thin walls of the cicatrix tissue here in times past. There was nothing found in the intestines to explain the recent bleeding therefrom.

Kidneys small; surface red and somewhat granular. Cortex narrowed. Bladder, uterus, and appendages normal. No amyloid reaction in liver, spleen, kidneys, or intestines.

Remarks.—Pain; tumour in epigastrium; enlarged glands; vomiting; wasting. Insidious commencement of illness were symptoms which I believe justified me in making the best diagnosis I could—because the most probable—namely, carcinoma of stomach. It will be seen how wrong my inference from the symptoms proved to be. Yet in nine cases out of ten this would have been not merely the more probable, but the only safe interpretation, of the clinical facts. These subdiaphragmatic abscesses, with their fistulous passages, localised peritoneal thickenings, and final outbreak into stomach, lungs, or intestines, are rare events in disease, though several are scattered through the medical journals, *vide* one recently in *Brit. Med. Journal*, October 11, 1879, p. 575. Had I paid more heed to the history than I did, I might not have erred so widely. But histories which date back more than a few months I am cautiously sceptical about. Unless you know your patient's mental calibre, and can rely upon their capacity as well as their desire to tell you truth, distrust of their statements as to facts happening long ago may be advised, unless the facts themselves are of a striking impressive kind. Directly the symptom of lung gangrene manifested itself I recanted from my original views of the case. Gangrene of the lung is not a common complication of cancer, as I told my class.

OPHTHALMOLOGICAL NOTES.

Translated by ARCHIBALD HAMILTON JACOB, M.D.Dub., F.R.C.S.I.,

Formerly Ophthalmic and Aural Surgeon to the City of Dublin Hospital and Dublin Eye and Ear Infirmary.

On The Surgical Treatment of Detachment of the Retina.

By J. Hirschberg.

Analysed by Dr. G. Claeys, of Gaud.

Among 22,500 patients, the author has met with 113 cases of detachment of the retina; that is to say, about five per thousand. He has never, unfortunately, been in a position to prove a case of spontaneous cure; ameliorations even, of any duration, have been rarely observed by him. He has given up the practice of puncture of the retina, as recommended by A. von Græfe, as he has never obtained by it any satisfactory results. The drainage of the eye, as proposed by M. de Wecker, he also rejects, considering the continued presence of a foreign body in the eye to be both irrational and dangerous. In ten cases of detachment Hirschberg has punctured the sclerotic and obtained the following results:—

1. Extensive detachment, of three months' duration, of the inferior half of retina: puncture of sclerotic: complete cure, which has now lasted for a year.

2. Detachment of nine months' standing, patient an old man; extensive defection of field of vision: puncture of sclerotic; relative cure; momentary enlargement of field of vision; amelioration of visual acuteness.

3. Complete cure lasting for a month; relapse.

4. Puncture of the sclerotic was successful as to the detachment, and ameliorated the disturbances of visual functions; a relapse, however, occurred during patient's stay in hospital.

5. Complete cure of detachment of recent date; relapse with hæmorrhage after traumatism; spontaneous cure: fresh relapse.

6. Puncture of sclerotic re-established the retina, which had been during several months detached; traumatism—relapse, with diminution of visual functions.

7. Traumatic detachment of several months' duration, with progressive contraction of field of vision; puncture of sclerotic did not re-establish retina, but enlarged the field of vision.

8 and 9. Detachment in two cases of strongly pronounced myopia; operation, to a certain extent, profitable to both patients.

10. Operation too recent to admit of operator being yet able to pronounce a decided opinion as to results.

M. Hirschberg is of the opinion that puncture of the sclerotic is to be recommended in all cases of detachment. The general result is to procure amelioration; this may, it is true, be only temporary, but as the operation does not entail any inflammatory reaction, it may, in case of relapse, be again practised without inconvenience. In all cases it is necessary that after the operation the patient should maintain absolute immobility, and should remain in hospital for a period of from three to four weeks.

As to the most favourable moment for operating, the author considers that the best is from eight to ten weeks after the first appearance of detachment. He has learned, however, from experience, that puncture of the sclerotic may lead to most favourable results in cases of detachment of from two to three—or even of from six to nine—months' duration, the retina having not yet lost all irritability. Puncture of the sclerotic may also have a certain semeiological value in the diagnosis of tumour of the choroid, commencing by detachment of the retina. Experience alone can decide on the proper moment for repeating the operation in case of relapse.

On the Employment of Eserine in Cases of Glaucoma. (a)

Since the close of the year 1877 eserine has been used by M. Knapp in numerous cases of glaucoma. Most satisfactory results have been obtained by him in certain cases of acute glaucoma, but in some he has found that the administration of eserine was not only useless, but even harmful.

In cases of chronic glaucoma M. Knapp has never either observed or obtained satisfactory results; on the contrary, in one case, of which he gives us a full account, the employment of eserine has had a harmful effect. He has taken notes also of a case of absolute glaucoma in which it has remained completely inactive. As to the employment of eserine preparatory to iridectomy, the author, although he has frequently made use of it, and fully recognises its advantages, warns us that in one case the use of this myotic engendered congestion, true inflammation of the iris.

In cases of corneal fistula, in which the use of eserine has been so highly recommended, the author has found it but moderately successful.

Finally, M. Knapp, taking into consideration the series of cases of glaucoma treated by him with eserine, believes

(a) By Knapp.—*Archiv für Augen und Ohrenheilkunde*, v.—vii. Pp. 257.

Digitized by Google

himself fully authorised in deducing from his personal experiments the following conclusions :—

The cure of acute glaucoma by the use of eserine is rare, and requires a considerable period of time ; its use, however, leads to temporary amelioration, which prepares the patient for iridectomy.

In cases of subacute glaucoma eserine is of doubtful utility.

In cases of chronic glaucoma, with or without the appearance of inflammatory symptoms, the action of the eserine is either null or harmful.

In cases of glaucoma occurring in a healthy eye during the closure of the other eye (on which iridectomy has been practised for glaucoma), eserine has no curative effect, that is to say, in those cases which have fallen under the notice of the author.

The instillation of eserine into the healthy eye for prophylactic purposes, when the other is attacked by glaucoma and awaiting iridectomy, has not been practised by M. Knapp, who considers, however, that this method may have its utility.

The danger of engendering iritis, and that also of provoking acute attacks, should be sufficient to warn us against the immoderate use of this powerful myotic. M. Knapp instils eserine only in those cases in which the eye on which he is about to operate has the following peculiarities, which might render the operation difficult :—Exceptional hardness of the globe, an exceptional pupil, and considerable diminution of the anterior chamber.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 5, 1879.

THE OPENING OF THE SCOTCH MEDICAL SCHOOLS.

WITH the exception of the Medical School of the University of Aberdeen, which opened on the 29th ult., the remaining Scotch schools were opened on the 28th, with the customary introductory addresses. It affords us pleasure to say that the various lecturers may fairly be complimented on the success which attended their forensic efforts, notwithstanding their conflict of opinion, and the inevitable operation of the "class-bias" in more than one instance. To this allusion will be made in the sequel. At the University of Aberdeen there was no special ceremony, and the only Professor who had a special opening address was Prof. W. D. Geddes, LL.D., who made a touching and deserved allusion to Mr. W. Jenkyns, who was recently massacred while secretary to the Cabul Embassy.

At the University of Edinburgh Professor Grainger Stewart indulged in his favourite apotheosis of the no doubt deservedly renowned school with which he is honourably associated. Claiming for it the honour of its antiquity, he pointed out the curious fact, in a medical point of view, elucidated by Mr. Fraser, in his report before the commission on the Argyll papers, that the office of coroner existed in various parts of Scotland in the fifteenth and sixteenth centuries ; and that an office then existed entitled that of principal physician within the isles of Scotland.(*a*) In 1681 the physicians of Edinburgh, who had long been aiming at incorporation, received from Charles II. a charter constituting them the Royal College. They knew unfortunately very little as to how the practitioners of those early times received their education. The surgeons learned their work by a system of apprenticeship, but their class education must have been very deficient. Although the teaching of anatomy was contemplated from the time of the incorporation of the surgeons, it must have been very inadequately performed, for in the year 1671 a skeleton of a Frenchman brought from Paris was regarded in Edinburgh as a very great curiosity ; and the fact that wealthy Scots sought to secure the services of foreign physicians ; that sometimes they went abroad in order to consult individual practitioners ; and that in one instance a rich Bishop of St. Andrew's called for consultation a physician from beyond the Alps—showed that the repute of native doctors was not then very high. In 1720 Dr. Andrew Sinclair, a graduate of Angers, Dr. John Rutherford, a graduate of Rheims, Dr. Plummer, a graduate of Leyden, and Dr. John Innes, a graduate of Padua, began, with the approval of the Town Council, to teach the theory and practice of medicine and chemistry in rooms connected with the old Hall of the College of Surgeons, and after a few years' work outside, the four teachers, upon their own petition, supported by the Royal College of Physicians, were admitted within the University as Professors. In 1728 the first steps were taken for the establishment of the Infirmary, and the arrangement was made whereby the apprentices of the surgeons and the students of physic should have the opportunity of observing the practice at

(*a*) As bearing on this, and the subsequent remarks of Professor Stewart, it may be noted that in the reign of James VI. two brothers of the name of Bethune were famous for the profession of physic in the islands of Islay and Mull. They were both educated in Spain, and were well versed in the Greek and Latin languages, but did not understand one word of English. The Islay physician held free lands of his Majesty as one of his physicians. He wrote a treatise on physic in Gaelic, and in the Gaelic character, with quotations from Hippocrates.—ED.

Digitized by Google

the bed-side. The earliest development of clinical study must certainly be regarded as very crude; but in the year 1748 a better plan was introduced, Dr. John Rutherford, who was then Professor of the Practice of Physic, establishing a series of lectures. Soon a number of his colleagues were associated with him in the arduous work. It was an immense advantage, Dr. Stewart considered, that the students thus obtained the opportunity of seeing the practice, not of one professor, but of three or four. Dr. Stewart then entered into details as to the requirements of an hospital, and especially into those of the new infirmary about to be opened. He contended that longer attendance on the hospital wards was required by students, and that the period of study for the degree of Bachelor of Medicine should be extended to five years.

At the Extra-Mural School of Edinburgh the inaugural address was delivered by Dr. Batty Tuke. He fancifully portrayed the wonderment of the professors of 1850, should they be released from Hades for a brief space of time and be permitted to visit the clinical wards of the Royal Infirmary. Let them picture to themselves that Syme, who was wont to amputate a limb in the simplest fashion, surveying the Annandale of to-day performing the like office, shrouded in a halo of carbolic spray generated by a steam engine, laving himself, his assistants, and his instruments in mysterious lotions, suspending the limb to be removed from a gallows, and investing the stump in complicated dressings. When he reflected on the space which had been traversed by medical explorers during the last quarter of a century, he confessed he stood somewhat appalled at the future of the medical student. He stood appalled even at his present position when he reflected how very much more scientific knowledge he had to acquire than the student of thirty years ago; how little improvement had taken place in the direction of his education towards a proper understanding of the science of physics, by means of which the advances of medicine and surgery had mainly been made; and how heavily he was overweighted to acquire a vast amount of non-essential knowledge. Not only had the candidate for University honours to be a better physiologist, anatomist, and pathologist now, but a better botanist and naturalist. He had no hesitation in saying that the aspirant for University honours was unnecessarily weighted by being called upon to be a naturalist or a botanist at all. As regards both subjects, the medical student was sorely taxed in pocket; and what was far worse, in brain power. He wondered whether the world had any conception of what a pillar to science the medical student was. He was taxed in pocket to support the teaching of a subject such as botany, which was of great importance to the community at large, but which had not only no bearing on his professional usefulness, but was a bugbear of the early years of his studentship, and the means of robbing him of most important time. Their examination in physics required nothing more than a smattering of knowledge which could be ground up in a few weeks, or even days; whereas as regards botany and natural history, months were required and wasted. After noticing that year by year the student of medicine was becoming more heavily weighted in the essentials also, especially by reason of the necessity of attending so many extra classes, Dr. Tuke went on to argue that whilst every one should take a University degree who could spare the time and the money necessary to secure it, those who could not should content themselves with one or more of the licences of the various corporations which granted qualifications in medicine and surgery, for by taking a licence instead of a degree a man was more likely to gather in four years a practical knowledge of his profession than by forcing into the same time all the essential and non-essential subjects demanded by the University curriculum. He was exempted from botany, natural history, and to a certain extent from chemistry, having only to acquire in that subject such an amount of knowledge as was sufficient for practical purposes, and he would then be able to apply the time thus saved in bringing himself face to face with disease. The practical knowledge he spoke of was not to be obtained by merely walking the hospital; it was in the dispensary where they could acquire an insight into those minor complaints which formed the staple of everyday practice; and he would rather choose a man for an assistant who could show his dispensary book filled with the names of patients whom he had personally attended in the Cowgate, than the holder of a gold medal for natural hisrory, or for the largest herbarium collected within twenty miles of Edinburgh. Dr. Tuke finally advised the study of insanity, and inculcated the wholesome lesson which few, however, sufficiently appreciate, in its scientific bearing, that the student should study with a doubting mind, and never accept as ultimate the opinions and statements of their teachers.

Of the absolute justice of Dr. Tuke's animadversions against the non-essential subjects; the multiplication of classes, and the crowding of the whole still into the short space of four years, no doubt can be entertained, and it is one of the arguments in favour of the much-needed medical reform at present under consideration, that the farming of their chairs by the professors is a clamant abuse, which ought at once to be put down by the strong arm of the law. Courses are at present spun out, multiplied, and called into existence, for no obvious reason than one which will only be too patent to the most careless observer. In certain universities there are *three* courses of surgery, two or three of materia medica, two of midwifery, *three* of physiology, and *three* or more of anatomy! We affirm most unhesitatingly that, with the exception of the anatomy classes, the supernumerary classes in all the other subjects are excrescences which ought to be lopped off, in the interests of the students, and of the science which professors affect to have so much at heart. All the experiments in connection with physiology proper might be demonstrated in connection with the theoretical teaching, for, so far as the value of the great bulk of them is concerned, there underlies the weighty fallacy that it is *hopeless to expect physiological results from pathological conditions artificially induced*, and that a science so based can have no claim to be termed physiology, while, in point of fact, physiology has always followed in the wake of practical medicine, and has never yet preceded it.

We propose commenting upon the other addresses in our next.

RESIDENCE ABROAD IN LUNG CONSOLIDATION.—II.

WHEN on examination of the chest an apex is found consolidated, it seems, as a rule, to be taken for granted that active mischief is a-foot. But is this really the case? Personally, we would feel warmly grateful to any observer who could tell us, in a great many cases, whether that consolidation has existed weeks, months, or years. The patient's real condition is not modified by the discovery of the consolidation; further than the influence the discovery exerts upon the future management of the case. Yet, ordinarily, the discovery is followed by hasty and excited action, as if acute illness were being encountered.

In a large number of cases the physician and the friends alike lose their heads; the occupation must be abandoned; the prospects in life, maybe after years of persistent toil, must be foregone; everything must be sacrificed; and the most acute mental misery occasioned, as well as monetary loss. For why? Because we are only slowly emancipating ourselves from the thraldom of Lænnec's views on tubercle. The dark shadow of his teaching overhangs the professional mind to a great extent, and the lay mind completely.

Once tubercle is established, and the patient is as certainly doomed as was Jephthah's daughter. That was the belief of the past. But what is tubercle? We have heard a physician say he would rather serve on the treadmill than be compelled to write an exhaustive treatise on the subject at the present time. When consolidation is established, it may last for years, without undergoing any active stage of change; and the only discomfort the patient experiences is from a want of breath on exertion, *i.e.*, so much lung is rendered functionally useless, and the only danger, often a remote one, is the risk of the part breaking down. There is no evidence of such a change setting in until moist râles are heard, and the temperature rises. The physician then having detected the consolidation—a very easy matter—has next to face a subject of infinite difficulty, viz., the aspect of the case.

It is not sufficient to jump to the conclusion that the condition is a recent one, imperatively demanding the complete overturning of the patient's existence. Such tumultuous action is neither creditable to our knowledge, nor advantageous to the patient. An exact calculation should be made as to the condition of the lung, the general state of the patient, and the family history; and this should precede the decision. The lung trouble may not dominate the whole subject so tyrannously as partial knowledge may suppose. Certainly a consolidated apex lowers the value of the life from an insurance point of view; but, if the researches of pathologists are to be credited, evidences of by past apicial mischief are commonly found in persons who have long survived any symptoms of lung-trouble; some of whom have reached a fair length of days without being conscious that there ever was anything abnormal in their chest. When a person with a consolidated apex begins to emaciate, either from night sweats, or diarrhœa, or indigestion, and if a woman, leucorrhœa, then this weak spot becomes a cause of anxiety. Just as in a regiment, when sent on a campaign, it is the weakest, the men who are diseased which break down first; so in the body when the organism is running down, then the injured structure is most likely to break down first. Defective nutrition, with the loss of blood-salts, is felt in the lowered tissue more than elsewhere; degeneration of the altered lung follows, and caseation reduces portions to a pulp; ulceration opens an air-tube, and the softened *débris* is expectorated, leaving a cavity. In the meantime the patient's life has been in most imminent danger. If the ulceration opens one of the pulmonary blood-vessels, probably the patient dies suddenly of hæmoptysis. At other times the patient dies of exhaustion; the result partly of a persisting high temperature, partly of the loss of blood-salts in the profuse night sweats.

Now let us seriously ask, Are we still in such outer darkness that we can only influence the lung condition and avert danger by sending the patient away from home and from England? Are the advantages to be derived therefrom sufficient to outweigh all other considerations? Does the discovery of a consolidated apex authorise exile, family sacrifices, often comparatively ruinous, and an upheaval of the patient's whole existence? Is it not possible that the cases which improve very markedly at Davos are just the cases which would have improved at home in a suitable locality and under judicious medical and hygienic treatment. Is there not a tendency towards regarding these health resorts as possessing powers so peculiar as to approach the miraculous? Consequently, a strong probability that cases which, nothing short of a miracle could cure, will be sent there—or order themselves there—to die in the delusive search after cure.

It is high time that a protest be made against the prevailing habit of ordering opulent patients away to foreign lands; if it were only on behalf of those unfortunate persons who, with lung disease, cannot afford to go abroad, and who are unnecessarily depressed thereby; who lose hope accordingly; and whose peace of mind is destroyed, and their prospects of life diminished, because they cannot reach those lands where they believe they could live and recover; but must stay at home and perish. Do those fashionable physicians who lightly order their wealthy patients abroad—in many cases because they wish a change, rather than any actual need—do they, in doing this, ever reflect on the poor consumptive lady's maid pining in a cheap lodging, whose remainder of life is embittered because she has not the means to reach those lands of which she has heard, or over-heard, so much; where phthisis cannot exist. Is it humane to extol so highly these far-away places? and, in doing so, to add to the sum total of human wretchedness in those who cannot reach them?

This is an aspect of the subject which we present to these physicians for their consideration.

LAST WEEK the French Anthropological Society received as a present from the venerable *savant*, Dr. Broca, two heads of Canaques, preserved in spirits of wine, and forwarded by a navy surgeon. One is that of Altai, the insurgent chief, and shows great intelligence and energy; and the other that of a medicine man.

Notes on Current Topics.

The Anti-Vivisectionists at Peterborough Again.

A few months ago we commented on the utter defeat the anti-vivisectionist party suffered at the hands of Dr. Thomas J. Walker, of the above town. Smarting under this defeat, Mr. Cooke, the itinerant lecturer of one of the anti-vivisection societies, took with him as allies a Mr. Gilbert, a medical man advanced in years, and Dr. Lee, of Lambeth, who has made himself notorious for his fierce opposition to all advance in physiological knowledge. Of course the action of the Bishop of Peterborough in the House of Lords excited the divine's wrath, and the meeting was in one sense an attack on Dr. Magee. But Dr. Walker was ready for them again, and, armed with the Bluebook of the Parliamentary Committee on Vivisection. Mr. Cooke opened the discussion with the usual rashly confident statements in which the anti-vivisectionists so constantly indulge. The progress of ovariotomy under Mr. Spencer Wells was denied, of course. Then the venerable Mr. Gilbert stated that surgery had made no progress during the last forty years. We benevolently trust he meant to have said that he individually had made no progress in surgery the last forty years. Dr. Lee denounced vivisectors with his wonted sonorous eloquence, and Bishop Magee, by implication, for daring to say a word in their defence. Dr. Walker disposed of them in a most effective manner, which was thoroughly appreciated by the audience. He was followed by Dr. Fothergill, of London, who pointed out some of the most recent advances made in therapeutics by well-directed experimentation. Mr. Cooke replied, and in his reply spoke of frogs being boiled alive, but on Dr. Walker handing him the Blue-Book he could not find the passage he referred to, and naively remarked that he would look it up. This tickled the audience immensely, and one voice suggested that he might have looked it up before with advantage. Despite the most obvious bias on the part of the chairman, the show of hands was "three to one" in favour of the Vivisection Act being left as it now stands; and a petition to Parliament, deprecating the imposition of further restrictions on the practice of vivisection, was signed by the chairman on behalf of the meeting. Probably in the future these anti-vivisectionist agitators will turn their energies to places where they will have a less able and energetic antagonist than Dr. Walker to encounter. These mischievous persons may be beyond the reach of reason or argument, but perhaps they may still be affected by defeat.

Communication of Typhoid.

The question of the contagiousness of typhoid fever forms the subject of an article contributed to the *Nineteenth Century* by Dr. T. J. Maclagan. After detailing the ætiology and pathology of the disease, and pointing out the necessity for the extremest precautions in dealing with the excreta of typhoid patients, the author of the paper concludes that, "Using the word contagious in its proper sense of communicable by contact, and regarding the typhoid poison as a parasite, whose nidus is in the glands of the bowel, we are led to the conclusion that the disease to which it gives rise, though undoubtedly infectious, can scarcely be contagious." Some care is employed, in the course of the essay, to distinguish the different meanings attaching to the terms contagion and infection. Dr. Maclagan insists on the zymotic action of the disease germs; and throughout the paper—only a short one, which will repay perusal—lays down simple and easily-observed rules for the guidance of attendants on the sick.

Opening Ceremony at St. Bartholomew's.

On Monday last, St. Bartholomew's Hospital was visited by their Royal Hignesses the Prince and Princess of Wales, when certain recent additions to the Hospital College were formally opened. The new buildings comprise several class rooms, a library, museum, and physiological laboratory. We can heartily congratulate the professors of physiology on the acquisition of the last improvement; and we hail the evidence it presents of the growing importance attached to the teaching of physiology and physiological chemistry in our medical schools. Dr. Klein may well be proud of the facilities he now enjoys for imparting sound practical knowledge in the subject of his lectures, and we shall look to see much good work issue from the St. Bartholomew's centre. The library is a pretty and conveniently arranged room; but we cannot help thinking that too limited anticipations of its growth have been indulged in. A medical library, to be a good one, must necessarily be a large one; so many allied sciences claim relationship with medicine, that a collection of works, illustrating both the history and the present state of the science and art of medicine and surgery, must occupy a space that the new library of St. Bartholomew's cannot possibly afford. Apart from this want of forethought, however, the room provided is admirably suited to the purpose for which it is intended. Of the other portion of the new structure the arrangements are very complete, the comfort of students being secured by the addition of a well-arranged cloak-room, and an excellent lavatory.

The formal opening took place in the new museum—a light and roomy chamber, with two galleries running entirely round it. The audience, assembled by invitation, numbered some three hundred, and included a few prominent members of the profession. Among others, Sir James Paget and Sir George Burrows were received by the students in a manner that testified the hearty goodwill subsisting between these notable chiefs and the juniors. Sir Sydney Waterlow, the treasurer, delivered his speech, which consisted of a careful *résumé* of the history of the hospital, compiled and extracted from the introduction to the calendar issued each year. The original points were a feeling reference to the death of Mr. Callender, and the loss sustained thereby; and a short description of the arrangements under which ladies were trained in the building to become fit to undertake the higher nursing duties of sisters and matrons. His Royal Highness's reply contained a congratulation on the prosperous condition of things existing in the hospital and school, an expression of his and the Princess's satisfaction at being present on the occasion, a hope that matters might continue favourably, and grateful thanks for the reception accorded to himself and his consort. He concluded by declaring the new building duly opened.

The Church and the Public Health.

THE long-continued and determined opposition of the Church to any mode of healthy recreation for the people on the day of rest; to anything approaching a people's Sunday; is at length yielding before the force of the assaults made on the bigotry and prejudice to which it has been chiefly due. It is gratifying to note that at the Croydon Conference of Churchmen, a resolution has been passed—after a fight, as may be imagined—approving of the Sunday opening of certain public institutions. It does seem incongruous that the profession which ought to be most nearly allied to the medical in its efforts to promote the bodily welfare of mankind, should, by its determined rejection of health-promoting schemes, so effectually bar the way of progress in this direction. With galleries, museums, reading rooms, and appropriate concerts at which to spend his leisure, the working man will naturally be less the slave of drink than he is now—driven to be so for mere comfort's sake; and hence, relieved from the punishment of his Sunday's orgie, he will feel the benefit during the week succeeding; and, as a result, he will be in every way a better member of society. In Manchester as many as four thousand people use the free libraries on Sunday. There is no reason why, with the advantages possessed in all large towns, the death and disease due to drink, and to a great extent due to Sunday drunkenness, should not be very largely diminished. In this assurance, then, it is pleasant to see the Church at last rejecting the misguided, beery, bigoted policy that has influenced it, bearing toward the movement for a healthy Sunday of intellectual recreation.

Discharged Lunatics.

OCCASIONALLY, it may almost be said frequently, cases occur in which life is lost through suicide committed by discharged patients of lunatic asylums. A death of this kind took place on Friday in Dublin. A lady who had been discharged as cured from an asylum, relapsing again into a condition of insanity, threw herself on to the ground from the roof of her husband's house. Falling a depth of forty feet, she died almost at once. The difficulty of accurately defining the actual mental state of a recently insane patient is undeniably very great. But the frequent accidents that result from the existence of this difficulty, render it highly important that some special attention should be devoted to the subject, if we are no longer to hear of these distressing accidents.

The Queen's University in Ireland.

A MEDICAL contemporary calls attention to the necessity that medical graduates of the Queen's University should register as members of convocation before the issue of a charter to the new university. By the University Education (Ireland) Act of last session all graduates who are members of the Convocation of the Queen's University at the date of the new charter, are, on complying with such conditions as the charter shall prescribe, to become members of convocation of the new university; whilst other graduates, in order to become members of convocation, must not only fulfil "the conditions," but possess "the qualifications" to be prescribed by the new charter. It is evident, therefore, that members of the existing convocation will be in a more favourable position than graduates as regards the convocation of the new university. At present all graduates of two years' standing are qualified to register, and can become life members of convocation on payment of one pound to the clerk of convocation.

Dublin Hospital Sunday.

THE annual collection is fixed for next Sunday, the 9th inst., and we earnestly trust that the occasion may be favourable for a liberal subsidy by the Dublin public towards this benevolent purpose. Last year the weather was unhappily most inclement on the day of collection, yet the amount subscribed was over average, which has already benefited the sick poor of Dublin and the surrounding country to the extent of upwards of £18,000, and this without diminishing the income derived by the hospitals from annual subscriptions. The amount of the collections has steadily increased, being in 1874 £3,306, in 1875 £3,619, in 1876 £3,873, in 1877 £4,107, and in 1878 £4,301. The reforms in the method of distribution of the Sunday fund which were decided upon by the managing council last year afford a reason for supporting it to those who had hitherto stood aloof because of the injustice and inequality of the system. There remains still much, very much to be done in the way of re-adjustment, before the subscribers can be satisfied that the public charity is honestly applied for the greatest benefit of the greatest number of sick poor, but we may hope that the Committee, having commenced to set their house in order in these respects, will persevere. This year the public may give with confident anticipation—next year they will require to be satisfied that something real and substantial has been done to correct the aberrations of hospital charity in Dublin.

A Nuisance in Chelsea.

WE have received a complaint from a resident in Chelsea of a very serious nuisance existing on a property owned by the Chelsea vestry. It is situated in the Lot's Road, and known as Lot's Road Wharf, where a refuse heap of an extremely offensive nature is lodged. The foul smells constantly emanating from the pile are of the most disagreeable kind, and cannot fail to exert an injurious influence on the surrounding atmosphere. The passengers from the embankment along the road rightly regard the continuance of the evil as a grave source of danger, even to themselves, and for those who are constantly subject to it the consequences must be still more injurious. This is no solitary instance, however, of the kind of abuse; and we deem it desirable, in the public interest, to draw attention to such violations of sanitary principles. In the present instance, it may be, the parish authorities are not directly responsible in the matter, but we doubt not that they will move in the direction of the abatement of the nuisance when it is brought to their notice.

Poor Miss Finch!

SOME modern novelists are fond of introducing medical cases to the reading public, and we believe the public like

Digitized by Google

such food. Wilkie Collins is particularly distinguished for this *penchant*.

In "Poor Miss Finch" we have an excellent example of his skill. We have two medical cases, one of epilepsy cured by nitrate of silver, and one of operative surgery.

The case of "Poor Miss Finch" has been considered over-drawn, and it has been said that after so many years an operation—say of artificial pupil—was out of the question. Did Wilkie Collins borrow from medical history, or draw from the philosophical transactions?

There is a very singular case reported in one of the old numbers, by James Wardrop, F.R.C.S., of a lady born blind, who received sight at an advanced age by the formation of an artificial pupil, in which the accuracy of Collins's description of the after-effects of the operation is singularly confirmed.

The lady was 46, had been blind from birth. Mr. Wardrop made an artificial pupil.

In returning home from Mr. Wardrop's house, with the eye covered with a loose piece of silk, she noticed a hackney coach, and exclaimed, "What is that large thing passing by?".....

"In the course of the evening she requested her brother to show her his watch, which she narrowly surveyed close to the eye. She remarked there was a dark and light side. She then looked at the chain and seals; remarking that one of the seals was bright, which was the case. Next day she refused to look at the watch, observing that she was confused by the visible world thus opened for the first time for her."

"Poor Miss Finch's" doctor was more particular about his patient, keeping her in a darkened room.

Those who have read the novel—and if any of our readers have not, and should desire to pass a few pleasant hours, we would advise them to—will remember Miss Finch's instruction in sight, and her disappointment at not being able to tell the shape of things, or to measure distance, or to distinguish colours.

In Mr. Wardrop's case we have the same phenomena.

"On the third day she observed the doors on the opposite side of the street, but mistook *their colour*. On the sixth day she saw still better, but was bewildered, from not being able to combine *the senses of sight and touch*, feeling disappointed in not having the power of distinguishing at once by the eye those objects which she could so easily distinguish from one another by feeling them. She had almost everything to learn, for although she could distinguish one object from another, she could not by the newly acquired sense discover what any object was, nor could she form any idea of its distance from her. She was, however, highly delighted with her restored vision."

Wilkie Collins has most artistically and scientifically described a good medical case, and his medical observations are both truthful and based on fact.

The Universal Pharmacopœia.

Amongst the reports presented to the International Medical Congress, recently held in Amsterdam, was one by Professor Gille, of Brussels, from the International Commission nominated two years before at Geneva to deal with the subjects of uniformity in medicine and the construction of an universal Pharmacopœia. This report is epitomised in last *Pharmaceutical Journal*, and is interesting in several respects, and especially because it discloses something like an abandonment of the idea of an international Pharmacopœia in some pharmaceutical quarters. It will be remembered that the principles agreed to at the previous International Medical Congress, held at Geneva in 1877, as suitable for the basis on which to construct such a work, were closely in accord with those adopted at the last Pharmaceutical International Congress, held in St. Petersburg, in 1874. This fact was accordingly communicated to the St. Petersburg Pharmaceutical Society, to which body the carrying out of the decisions of the Pharmaceutical Congress appear to have been entrusted, through its President. This, however, led to no response. On the other hand, the St. Petersburg Society is said to have decided in March last to take no part in the next International Pharmaceutical Congress, which was to have been held this year in London, and in July, to have sent back to M. Mehu, without a word of explanation, the scheme for an universal Pharmacopœia elaborated by the Paris Society of Pharmacy, which had been referred to a committee of pharmacists to report upon. Under these circumstances, the present reporters think that it devolves upon the medical profession to take up the question of the universal Pharmacopœia, and to apply the stimulus necessary to arouse the flagging interest of pharmacists. The report proposes that the commission should be authorised to select a Government to which application should be made to open negotiations with other Governments, with a view to the nomination of an international commission to deal with the subject, utilising as far as possible the work already done. This commission, it is proposed, should commence its labours immediately after its nomination, and the members of it to report progress to their respective governments every two years, the subjects upon which they are not in accord being reserved for further investigation. The report and its recommendations were agreed to by the Medical Congress, and it was decided that the scheme of the Paris Society should be printed in the official proceedings of the meeting at Amsterdam. It was also decided to add to the members of the Geneva Commission, Messrs. Sayre, of New York; Dechambre, of Paris; Ernest Hart, of London; Warlomont, of Brussels; Goye, of Amsterdam; and Palasciano, of Naples.

Animal Vaccination in Holland.

Dr. Charles Drysdale describes in the *Times* his experiences of animal vaccination in Belgium. As member of the International Congress of the Medical Sciences held in Amsterdam, he visited the general hospital at the hour when vaccination from the calf was going on there. Dr. Crocq, of Brussels, Dr. Palasciano, of Naples, the eminent physician and deputy, who was the chief means of inducing the public authorities in Belgium, France, and Germany to adopt animal vaccine, &c., were present. The room was full of mothers, with their infants ready to be vaccinated direct from the calf, which reclined comfortably on a table, while the physician performed the little operation of transferring lymph from the animal direct to the arm of each infant. He says that three-fourths of all the vaccinations in Amsterdam are now per-

Digitized by Google

formed direct from the calf in this way. In Belgium also the same practice is equally popular in Brussels, under the able direction of Dr. Warlomont.

That gentleman informed me at the Congress that he intends coming to London this winter to endeavour to make our public authorities take up the matter; and he would submit that they ought to do so. 1. Because in times when small-pox is epidemic, a quite unlimited supply of calf lymph can be obtained in about five days, while human lymph at such times is often quite insufficient. 2. Because when we, as he believes we have the right to do, force parents to vaccinate their children, we ought to give them the choice between human and animal vaccine. Vaccination, being the greatest triumph of hygienic science, should be made as popular as possible.

Coroners and their Victims.

THE unhappy general practitioner is thought by many gentlemen who occupy the coroner's seat to be a fair mark at which to direct uncalled-for and often grossly unjust condemnatory remarks. A case illustrating this agreeable propensity has recently occurred in Hull, where Dr. Ballinghall has been censured in the most undisguised manner by the jury; and this censure further endorsed by the coroner. The facts of the case are briefly these: Dr. Ballinghall, after a very hard day's work, was called to a case late at night, and with the most justifiable reasons he did not proceed to it until assistance was too late, and the patient beyond all hope of aid. The circumstances were such as entirely to exonerate the medical attendant from any real blame in the matter; but in spite of this he was branded by the intelligent twelve and their chief, for the time, in terms of most unmitigated reproof. We urge that the responsibilities of a coroner's position require that it should be filled by one able to discriminate nice questions of rule and conduct; and the necessity points to the fact that many of those now in possession are eminently unfitted in this respect to discharge the proper functions of the office. Dr. Ballinghall has our hearty sympathy.

Irish "Crowners" Law.

LAST WEEK some remains, supposed to be those of a child, were found in the ceiling of a house near Kilkenny. An inquest being held, two of the jurors expressed their doubt that the bones were human, and wished to have a medical opinion on that point but the Coroner objected, stating that there were persons present who were satisfied that they were human remains. The charge of the Coroner is reported in the local paper in the following terms:—"Gentlemen, you have heard the evidence; we cannot find by whom the child was left there, but it *was illegal and unlawful to find it there.* Neither can we learn was it alive or not, nor its sex. It must have been there a long time. I have drawn up the following verdict, which I think you will agree to, viz.—'That the remains were found illegally and unlawfully concealed by some person or persons to us unknown. From the size of the skull and bones we believe them to have been a full matured infant at its birth, from the years of decay unable to say whether male or female.'"

AT the Croydon Congress last week, Dr. Norman Kerr read a paper on "The Mortality from Alcohol and Preventive Mortality," in which he stated that he estimated the annual mortality through intemperance on drinks at 120,000, of whom 40,500 succumbed through indulgence, and the remainder through poverty, disease, accident, or violence arising from the indulgence of others.

THE late Mrs. Charlton, of Priory House, Dudley, whose death was announced last week, has by her will left the following magnificent bequests:—Guest Hospital, Dudley, £10,000; Dudley Dispensary, £1,000; Wolverhampton Orphanage, £1,000; Institution for the Deaf and Dumb, Asylum for the Blind, Eye and Ear Infirmary, Birmingham, and Asylum for Idiots, Knowle, £300 each.

AT a meeting of the Council of the Hospital Saturday Fund, held on Friday last, it was arranged that the distribution of the money collected this year should take place on the last Saturday in November, or the first Saturday in December. It was announced that the "Employers' Fund" was progressing favourably. In spite of the great depression in trade it is expected that the distribution will exceed that of any previous year.

WE understand that the late distinguished surgeon, Mr. Callender, whose obituary appeared in our last, was to have been present at the opening ceremony in connection with the Massachusetts Medical School, Boston, United States; but a telegram was received at the last moment that he was too ill to attend. This was about the middle of September, so that he must even then have been in grave danger.

CHOLERA is reported to be making terrible ravages in Japan. The epidemic made its appearance last April, and by the middle of August over 40,000 cases had proved fatal. Up to the end of September the number of victims is said to have reached 100,000. The Government has tried to arrest the progress of the epidemic, but unfortunately the quarantine regulations have been disregarded by foreign vessels, and the result is that the cholera is spreading in all directions.

DR. HUGHLINGS-JACKSON and Dr. Buzzard intend delivering a series of six clinical lectures alternately, each Thursday, from November 13 to December 18 inclusive, at the National Hospital for the Paralysed, Bloomsbury. The former will take "Diseases of the Brain" as his subject; the latter "Diseases of the Spinal Cord." The lectures will commence at 5 p.m., to which practitioners and senior students will be admitted free on presentation of visiting card.

ACCORDING to the Registrar-General's returns, the rates of mortality per 1,000 last week in the principal large towns were—Wolverhampton 15, Bristol 16, Portsmouth 16, Bradford 18, Glasgow 18, Edinburgh 19, Leicester 19, Norwich 20, Sheffield 20, Birmingham 20, Newcastle-upon-Tyne 21, Brighton 22, Plymouth 22, Hull 22, Nottingham 22, Leeds 22, Sunderland 22, London 23, Salford

Digitized by Google

24, Oldham 25, Manchester 26, Liverpool 26, and Dublin 32.

THE death-rate from the seven principal zymotic diseases last week ranged from 0·0 and 0·7 in Wolverhampton and Plymouth, to 5·5 and 5·7 in Liverpool and Newcastle-upon-Tyne. Scarlet fever showed the largest proportional fatality in Bradford, Dublin, Manchester, Liverpool, Sunderland, and Newcastle-upon-Tyne. In Birmingham 5 deaths were referred to fever, and 2 to diphtheria. The deaths from measles were numerous in Liverpool and in Leeds. Small-pox caused 7 deaths in Dublin, 5 in London, and one in Birmingham.

IN the principal foreign cities the annual rates of mortality, according to the most recent weekly returns, were —in Calcutta 24, Bombay 34, Madras 43; Paris 24; Geneva 20; Brussels 23; Amsterdam 20, Rotterdam 20; The Hague 21; Copenhagen 27; Stockholm 21; Christiania 17; St. Petersburgh 31; Berlin 25, Hamburg 24, Dresden 23, Breslau 29, Munich 38, Vienna 23, Buda-Pesth 31; Rome 30, Naples 23, Turin 22; Alexandria 40; New York 24 per 1,000 of the various populations.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

ST. ANDREWS.—MEDICAL OFFICER OF HEALTH.—At a special meeting of the general committee of the parochial board, held on the 25th ult., for the purpose of appointing a medical officer for the burgh, Mr. John Jamieson Kingask presiding, Dr. James A. Lyon, M.A., Edinburgh, was unanimously elected to the vacant office. There were eight applicants.

HEALTH OF EDINBURGH.—Dr. Littlejohn's report for the month ended 30th September last shows that there have been 297 deaths, giving a death-rate of 16·19 per 1,000. The deaths of the past quarter numbered 901, giving a death-rate of 16·37, a lower death-rate than any quarter during the past five years.

HEALTH OF GLASGOW.—The report by the medical officer for the fortnight ending the 18th ult. states that, during the fortnight preceding there were 379 deaths registered, as compared with 348 the fortnight preceding, representing a death-rate of 47 in place of 16, of 18 instead of 17 on our lower estimate of the population). The death-rate in the first week of the fortnight was 18; in the second 16. The number of deaths of persons aged below one year was 82, in place of 90; and of persons aged 60 years and upwards 55 in place of 52 as compared with the previous fortnight. The number of cases of fever registered was 82 in place of 72, viz., 66 of enteric fever, 10 of typhus, and 6 undefined. There were also 76 cases of scarlet fever, 59 of whooping-cough, 37 of measles, and 16 of diphtheria, which were the occasion of sanitary assistance and supervision in various ways. The numbers in the hospitals of the board have steadily increased during the last two months, until they are now nearly doubled.

THE UNIVERSITY OF GLASGOW. FACULTY OF MEDICINE.—The Winter Session of the Medical Faculty of this University was opened on the 28th ult. Professor Balfour, the newly-appointed Professor of Botany, delivered the introductory address in the lower hall of the museum. Principal Caird presided, and there was a full attendance of the members of the medical faculty. Professor Balfour was received with loud applause, and delivered an interesting and instructive address. He contrasted with much clearness the functions of plant and animal life. Referring to the agitation for medical reform, as became a newly-appointed professor, he viewed with alarm the contemplated changes. It was hard to conceive (and it will be equally hard for any other person to conceive) how the lowering of the standard of education to a minimum would tend to the better protection of the public, or how the exclusion from the curriculum of the study of those sciences which even the reformers designated the fundamental medical sciences would produce practitioners more fitted for the work of their profession. In concluding, Professor Balfour urged upon the students, at the outset of their career especially, a due attention to the natural history sciences.

OPENING OF THE EDINBURGH NEW ROYAL INFIRMARY.—The New Royal Infirmary for Edinburgh was formally opened on the 29th ult. by Lord Provost Boyd, in the presence of a large assemblage of contributors and members of the various public bodies. The cost of this building has been the large sum of £350,000, of which nearly £100,000 has been subscribed, the greater part of the remainder being supplied from the accumulated funds of the institution. This enormous increasing hospital accommodation, the growing debt on such institutions, the extent to which hospitals are taken advantage of by all classes of the community, and the incessant appeals to the public to maintain them, involve questions of serious import, not only to the medical profession, but to society at large.

A DINNER AFTER THE ANCIENTS.—At the annual dinner of one of Dr. Low's (High School) Latin classes, held in Messrs. Ferguson and Forrester's, Glasgow, on the 28th ult., the following was the bill of fare :—

CIBARIORUM TABELLA.
Clara sorbitio vegetabilis.
Sorbitio ostreorum.
Asellus et conditura ostreorum.
Apuae frixæ.
Ostrea coccisa frixa.
Segmina ovina.
Caro assa.
Meleagris et lingua.
Vegetabilia in varietate.

Literary Notes and Gossip.

St. Luke, a journal which has been on the *tapis* for many months, has at last made its appearance as "a clerical, medical, and art review." Its leanings under the first of this descriptive heading, are extreme high churchism; under the second, decidedly lunatic; and under the third, not yet fully developed. We wish our contemporary every success, but think it would have a better chance of attaining it were its conductors to stick to one specialty.

* * *

THE new number of *Brain* is an excellent specimen of

Digitized by Google

what journals taking up a special branch should be, though we fear the number on whom editors and publishers can rely for support in such ventures is not encouraging. *Brain* should be read by all who have sufficient brain power to grasp its valuable articles and original researches, and by all who desire to educate themselves up to this psychological point. Such a quartett of editorial talent as Bucknill, Crichton-Browne, Ferrier, and Hughlings-Jackson, is not often associated on one journal, and we should be glad to hear that their efforts were more liberally appreciated.

* * *

Recent numbers of the *Financial Record*, *Economist*, and *Railway Review*, contain a leader on the position of the medical profession in relation to insurance companies—life accident insurance. The position of a medical officer to an insurance company may be looked at under three heads: first, if referred to a first-class company; secondly, if referred to a second-class company; thirdly, if referred to a rotten company. There are a few of the first-class, a great number of the second, and a still greater number of the third. We are not called on to give names.

* * *

First-class companies have first-class men as their medical officers, second-class have second-class men, and third-class have men to suit their requirements, so that the duties and responsibilities are felt very much in proportion to the time, spirit, and position of the office with which each medical officer is connected. After this division of ours, we need not say one word about the well-meaning article of the *Financial Record*, *Economist*, and *Railway Review*. The profession are fully alive to the responsibilities in connection with life assurance, and full instruction is given to students on the subject, so that the suggestion of these journals is quite unnecessary.

* * *

We have been taking a cursory glance at the "New Dental Register," just issued under the auspices of the General Council of Medical Education and Registration, and can understand what an immensity of labour and anxiety the compilation of a first issue of such a work must be; and we can only congratulate the editor, Mr. Miller, upon the conclusion of his heavy task, and to add that everything officially affecting dentists or surgeons practising dentistry will be found therein, from the application to be registered, to every Act of Parliament relating directly or indirectly to dentists.

* * *

The Registrar of the General Medical Council certainly performs prodigies of literary work. Not content with his ordinary avocations, and in addition to the extra labour entailed this year in the production of a New Dental Register," he finds time to edit volumes of mathematical questions, with their solutions, which are certainly the reverse of child's-play. Among the contributors to these abstruse volumes, is our learned friend, Dr. Samuel Haughton, F.R.S., otherwise, medicine would be unrepresented, he being the single exception therein to prove the rule that "medicine is not an exact science" at present.

* * *

"Gray's Anatomy" made for itself a deserved reputation. It is a large and formidable volume for the student. We notice that a small compendium, called the "Pocket-Gray, or Anatomist's *Vade Mecum*," has just been produced, and we have pleasure in saying that it is one of the best little compilations we know of. It is small, well-printed, containing a very large quantity of matter, and as it can be easily slipped into a pocket, the student can have this friend with him to turn to, as he walks from home to hospital, and thus can "run and read."

* * *

We have just received a very pretentious work: "Hygiene and Public Health," edited by Dr. Brutz, so well-known in connection with "Ziemssen's Cyclopædia," and so *dear* to the subscribers. It is published by Wood and Co., New York; Sampson, Low, Marston, Searle, and Rivington, London. We hope in a few weeks to review it.

* * *

Dr. Æneas Munro, nothing daunted, has once more essayed in his new work, "Deaths in Childbed," writing in the English language. His last book, and obviously his first, "On Nursing," created a great deal of amusement in medical, and other polite circles. The countrymen of Hume and Dugald Stewart, were naturally enough led to hope, that a medical graduate of the University of Edinburgh would be, at all events, conversant with the grammar of the language spoken in these islands. A perusal of this book disappointed not a few of them. The honest opinion of an intelligent lady of our acquaintance, on looking over the pages of "Nursing the Sick," was that "it seemed the work of a foreigner, imperfectly acquainted with the English language." The book, if we mistake not, fully annotated, lies on the shelves of the "Faculty Hall Library," Glasgow, and it may beneficially be taken home by anyone in an atrabilious mood.

* * *

Midwifery practice is becoming rather a troublesome and onerous part of the general practitioner's work. Now there is an association on the *tapis* to prevent practitioners attending any confinement, if scarlatina, or any other zymotic affection be prevalent. What are the women to do? The ideal accoucheurs of the future, will have, before every confinement, to take a carbolic bath, to have a new suit in readiness for each case, to give up attending midwifery if he has a fever patient, and if attending, or likely to attend, a parturient, to refuse all other patients, to carry with him to all confinements a bag with all the instruments of precicision (advertised in Maw, Son, and Thompson's list of Gynæcological Curiosities), so that he may be prepared for any of the emergencies which occur in midwifery experience; to carbolise his patient's vagina before, during, and after, labour, and in fact to live in an antiseptic atmosphere. Thus we may have the process of parturition brought to such perfection that no deaths ever occur owing to infection, and the ideal practitioner of the future will be able to attend the Obstetrical Society, and boast *with truth*, "that he has never lost a patient."

* * *

Foreign degrees are still exciting a considerable degree of attention. There is evidently a desire amongst the profession for letters after their name. But it is not confined to medical practitioners. What a number of F.G.S., F.S.A., F.A.S., &c., &c., there are knocking about? What is the precise scientific value of a title which costs about a guinea a year, and for which there is no qualification required, but an introduction by a friend, and payment of the said guinea or guineas? In these so-called scientific societies, there is a blending of elements. The drones and the workers are classed together, and certainly the time has come for some of these societies, which have the right or power of conferring fellowships, to draw the line, and to put a stop to the custom of admitting anyone to their fellowships.

* * *

There is a class of men in England who are deserving of having some recognised titles. We allude to workers in original research, to the men who devote themselves to clear up the nature of some hidden or obscure point in connection, it may be, with plants, animals, or man; with geology, or some other subject. We know a number of such men, and we regret that such workers are simply herded together, it may be in a Geological Society, with a number of *dilettanti*, who know nothing whatever of the subject of geology. Our scientific societies must either draw the line, or the *original* workers must form a society of their own; admission to which should be strictly confined to men who have claims to be considered men of science, in virtue of what they have done, or are doing, in any department of science. There is, of course, the Royal Society. This excellent Society does not meet the want we allude to.

* * *

In our last "Literary Notes" we asked for curiosity sake some information as to the expenditure by those who uphold the non-alcoholic doctrines, on the literature of that body,—to wit, on the *Alliance News*.—Although delighted that "Teetotalers" support their views in so handsome and practical a manner, we think it will surprise a good many to hear that from October, 1878, to October, 1879, the enormous sum of £19,878 1s. 11d. was expended in the promotion of this cause in the shape of literature, lectures, tracts, office expenses, &c., leaving a balance in hand of £1,598.

* * *

It will be seen that the propagandism of Alliance principles is rather expensive. What is the result? Is it worth the expenditure? For ten years, taking a rough estimate,

Digitized by Google

the organ of the Alliance and the agencies have cost about £20,000 a year, so that the drink traffic has caused another indirect expenditure of £200,000.

* * *

We wonder how much a certain popular lecturer has had of this? Rumour reaches us that, as much as £100 has been demanded by, and paid him, for a day's work; £50 being a not uncommon sum for disinterested services in this direction. Probably, both lecturers and agents would be sorry to find their occupation gone, but if the subscribers are satisfied, we must leave them in that happy state.

* * *

A wonderful work has lately been done by children's hands—a work which will, in all probability, gladden the hearts and help to lighten the sufferings of many little weary ones in the Children's Hospitals throughout the country. Early in the present year the proprietors of *Little Folks' Magazine* instituted a prize competition for coloured copies of the "Little Folks' Painting Book," the prominent feature of the scheme being that all the books were eventually to be distributed among the Children's Hospitals, as a Christmas present from the young artists. In response to this invitation, hands and brains have been very busy for six months past, and during the closing days of the competition the number of books received by the editor has, we understand, averaged as many as 500 *copies a day*, thus bringing up to *many thousands* the total number of Painting Books received, which will be available for distribution among Children's Hospitals. We are not informed in what manner the publishers, Messrs. Cassell, Petter, and Galpin, of London, propose distributing this immense number of hand-coloured picture books, but they will doubtless be glad to receive applications from members of the staff of Children's Hospitals throughout the Kingdom.

* * *

New Books and New Editions.—The following have been received for review since the publication of our last list, Oct. 15th:—"A Treatise on Chemistry," by Professors Roscoe and Schorlemmer, vol. ii., part 2. "An Atlas of Human Anatomy," by Mrs. Fenwick Miller. "St. George's Hospital Reports," vol. ix. "The Riviera," by E. J. Sparks, M.A., B.M. "Annals of Chemical Medicine," vol. i., by J. L. W. Thudichum, M.D. "Saint Thomas's Hospital Reports," New Series, vol. ix. "Syllabus of a Course of Lectures on Physiology," by J. Burdon Sanderson, M.D.

* * *

Pamphlets.—The following have been received since the publication of our last list, Oct. 15th:—"Report on the Pathological Histology of Epizootic Pleuro-pneumonia," by Chas. S. Roy, M.D. "Neurasthenia," by G. M. Beard, M.D. "Morbid Fear as a Symptom of Nervous Diseases," by G. M. Beard, M.D. "Annual Report on the Health of Kensington," by T. O. Dudfield, M.D. "The Functional Stage of Granular Kidney," by R. Saundley, M.D. "Otorrhœa, or Discharge from the Ears," by W. Douglas Hemming, F.R.C.S. "Overcrowding and Crime." "Observations and Comments on Certain Convulsive Disorders," by Hy. Day, M.D. "On the Electrical Excitability of the Skin," by Drs. Tschiriew and de Watteville. "Clinical Charts," by L. J. Hobson, M.B. "A Bird's-eye View of the Scientific Claims of Vivisection." "Water for Nothing," by S. Hibberd, F.R.H.S. "Sanitary Fallacies," by W. H. Corfield, M.D.

Correspondence.

HOW THE POOR-LAW MEDICAL OFFICERS OF IRELAND ARE TO LOOK FOR A REASONABLE SALARY FOR THEIR SERVICES?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In the copy of the *Press* of the 22nd inst., I read, with some interest, the letter of your correspondent, "Scarlet Runner." In that letter he states that union amongst the poor-law medical officers is necessary (and here I agree with him), in order that we may be able to obtain reasonable remuneration for our services. As I don't think there is any chance of bringing about that union by the means "Scarlet Runner" suggests, would you kindly allow me to put before your readers the only method, which, to my mind, appears practical, and I hope the Council of the Irish Medical Association will give it their consideration. As soon as the time arrives for soliciting names of members to join this Association for the coming year, let the Secretary, instead of applying to each person individually, as heretofore, now apply to the workhouse medical officer of each union, to get *every medical man residing in that union* to become a member, on conditions of signing the following agreement, which should be sent, accompanying the application to become a member.

We, the undersigned, residing in ——— union, do hereby promise and agree not to undertake the performance of medical duties of any dispensary district from this forward for a salary under £250 per annum, exclusive of vaccination and registration fees, nor the duties of any workhouse hospital under a salary of £200 per annum, exclusive of salary as Consulting Medical Officers of Health.

Signed this.....day.....1879.

(Signature here).

I don't think there would be any difficulty in getting every poor-law medical man in Ireland to sign this, and subscribe at the same time, half a guinea to the Association. In case of big practitioners in cities, it would be unnecessary to get their signatures of course, but if they could be got to subscribe on those terms, so much the better, and from my experience of them, I must say that they are inclined to help their less fortunate brethren in every way they can. There is another class of medical men, those who are not long qualified, and who are waiting for appointments, home or foreign. The subscription may be an obstacle in their way, but the poor-law medical officers should get those to join at any cost, even pay the amount of the subscription for as many as reside in the union. I don't think their number would amount to one in every two unions.

To some of your readers, the salaries named in the agreement to be signed may appear large, but let any of your readers show me any body of public men, whose education costs so much time, trouble, and money, working for a smaller salary. The nearest body to the Poor-law medical officers in that respect, that I can see, are the inspectors of national schools. There education is not quite so expensive as ours; their duties may be a little more onerous, but certainly there is no comparison as regards disagreeableness and danger, and look at their salaries. They commence with £250 per annum, *exclusive* of *car hire;* their salaries are increased £10 a year for the first ten years, and £15 a year for the second ten years. Besides this, they have chances of promotion, which may give them a far larger salary in less time, although at the end of ten years' service they are receiving £350 per annum, and at the end of twenty, £500 for length of service alone. I think, then, that your readers will so far agree with me, that the sums mentioned above are rather below than above what are justly due to us.

If, after signing the agreement, any person should break through, and accept of dispensary or workhouse, at a lower salary, he should be immediately reported to the Secretary of the Irish Medical Association, who should summon a meeting of Council, the offender should then and there be ignominiously expelled, and the proceedings fully reported in all the local papers, and in addition, he should be blackballed and coldshouldered by the entire profession, as "Scarlet Runner" suggests.

The signatures and subscriptions obtained (and I say the signatures and subscriptions of every man in Ireland could be obtained if the Irish Medical Association set to work properly); the Irish Medical Association need not be running every second day with cap in one hand and a petition in the other, seeking for justice by instalments; they could then and there make *their own terms* for the unfortunate Poor-law medical officers, and they would also put the Association on something like a proper footing. They could then *suggest* to the Local Government Board the *propriety* of increasing our salaries; and if they refused, they could put their heads together, and try whether they could not be *compelled* to increase them. Until this, or something similar to it is done, let "Scarlet Runner," and every other "runner" hold their tongues, and let the Irish Poor-law medical officers remain as they are, game for any scoundrel who presents them with a medical relief ticket, unless they are dancing attendance on *his honour*, the hardest worked and worst paid public body in Europe. Until they unite by those means (and to my mind, this appears to be the only way of bringing about their union), let them remain as they are, with scarcely the means to support life, and certainly no earthly means of putting a

Digitized by Google

shilling by for the rainy day; let them keep themselves in a position in which they dare not look crooked at any individual, from the smallest cow-boy committeeman to the biggest gun on the Local Government Board, and lastly, let them remain as they are, with little or no social standing, or, at least, certainly nothing near what their profession and education entitle them to.

I am, &c.,

ONE WHO RECEIVES LITTLE MONEY, AND LESS THANKS FOR HIS SERVICES.

TETANUS FOLLOWING THE ABUSE OF HYPODERMIC INJECTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I think the above title of the case reported in your last issue does not accurately express the nature and cause of the malady from which the patient died. I am of opinion that the neuralgia caused the tetanus, and that the morphia injections, so largely used, "staved off" for a considerable time the "evil day" from the poor patient, who finally gave in to the blood disorder, and the tetanus therefrom. I am led to believe this from my remembrance of a case of trismus in a young woman (rheumatic) which I treated successfully, five years ago, with hydrate of chloral, Fleming's tincture of aconite and bromide of potassium, and with chloroform inhalations. At the time I did not deem the case of sufficient importance to publish; but having very recently succeeded in saving a bad case of traumatic tetanus in an interesting little girl of nine years old by the same means, I intend shortly to collect my notes of the first case, and to publish both cases together with your permission in the columns of the *Medical Press*.

Yours, &c.,

J. O'FLANAGAN.

Houghton-le-Spring, Durham.
31st October, 1879.

[We shall be glad to receive these cases from our correspondent.—ED. M. P. & C.]

"WHAT DID DR. DAVID WILSON SAY?"

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In every country there are to be found in its records extraordinary cases of innocent persons being incarcerated in order to benefit certain interested parties, or for *secret state reasons*, and, whatever the gentlemen of the long robe may assert to the contrary, these instances of injustice are so numerous and glaring, that but little credence can be placed in their statements, and neither can we divest ourselves of the opinion that the ways of justice are past finding out, and that the technicalities of law are an incomprehensible jumble, so as to prevent truth coming to the front and shaming falsehood and deceit. Judges and barristers are but men, and are consequently liable to err, and, being so, it is no want of respect to those who dispense justice to observe that sometimes their decisions are of such a nature as to make one regard them in the same light as we regard the "unjust judge" in holy writ. We must, as thinking men, question the wisdom of these decisions when they are antagonistic to indisputable facts.

A few days ago a pamphlet was sent to me entitled "What did Dr. David Wilson say?" and as it contains the medical evidence which was suppressed during the trial of the Claimant anent the *peculiar malformation* of his penis, I cannot but help thinking that a few extracts from it will be exceedingly interesting to your readers, not only as establishing the fact of the identity of the Claimant, but as an anatomical curiosity deserving record in the pages of your widely-read journal.

"Has he a malformation?—He has a peculiar formation.

"What is that peculiar formation?—The penis retracts in a most unusual degree, so that on one occasion when he passed water, which had been retained for some hours at my express wish, the penis was absolutely out of view, and nothing whatever of it could be seen but the orifice from whence the stream issued. Yesterday I found the member more turgid, but I endeavoured to push it back towards the neck of the bladder with which it is continuous, and found it perfectly easy to push the whole member out of sight.

"Dr. Kenealy—Now my learned friend will cross-examine him, my lord.

"The Lord Chief Justice—Whatever the theory, still there is the fact?—There is the fact."

Further on we read—

"Mr. Hawkins—Am I to understand you, then, that was not so in passing water; the member was not at all protruding?—It was not protruded.

"Not at all?—Not at all.

"Did you ever meet with a case such as you described in the whole course of your experience?—I never have.

"Mr. Justice Lush—You never met with such a case before?—I never have.

"Mr. Hawkins—Did you ever examine anybody before?—I have seen, I should think, a few thousands of people, and examined them, and had to do with the passing of catheters, in very old men at times, whose virile parts are generally considerably contracted, but nothing like what I saw here."

The preceding establishes a fact. Sir A. Cockburn acknowledged it to be such, and this fact is in favour of the Claimant. It would be a most astounding thing for two men to be alike in this particular, and I do not believe another medical man has seen a similar case. I could give several more extracts, but my letter would be taking up too much space; and it may be that some of your readers will think it a bore, short as I have made it, after so long a decision of the case. If so, my excuse must be found in the fact that the pamphlet has only just appeared—at least, so far as my knowledge goes; and my love of the truth in spite of lawyers.

I am, Sir,

A FELLOW OF THE ROYAL COLLEGE OF SURGEONS.

[We have given space to the foregoing letter, lest by its refusal, we should be charged as the majority of journals have been, with "persecution" of the claimant. But we are not to be considered as entertaining any doubt as to the justice of Orton's sentence; and, considering that the testimony of Dr. David Wilson was so easy of corroboration, and that it was not effectively corroborated, we must conclude that any abnormality that may have existed was unimportant.—ED. M. P. & C.]

VACCINATION AND ITS SUPPOSED DANGERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—At a time when the public mind is disturbed on the subject of vaccination, and public confidence sought to be shaken, it becomes, I think, the duty of every man practically acquainted with the matter, to give the result of his experience and his opinion in the calm and unprejudiced manner which the gravity of the subject demands. Until the question of vaccination is thus met, individual indignation will avail nothing, and medical evidence based on hearsay or book information becomes worse than useless—it is mischievous and unjustifiable. Now, that vaccination in itself is dangerous, or attended with the evil results laid to its charge, I entirely deny.

No reasonable person or competent judge would condemn any valuable operation, if followed by death, when performed on an unsuited case, or at an improper time; no one would condemn the use of opium and its various compounds, even if followed by a fatal result, because through the ignorance or carelessnes of the prescriber it was administered in a case where such treatment was inadmissible. Thus it is with vaccination; children are continually brought out of health from improper diet, with irritative fever from dentition, or imbibing the milk of a diseased or intemperate mother; no information given, or perhaps sought, on these important subjects, and with the lymph taken, perhaps from a child of whom nothing is known, and vaccinated from a vesicle at an improper time, when the lymph has become perhaps pus; is it to be wondered at that various diseases crop up, which, if this simple operation were carried out with the care and attention it deserves, would not follow so valuable a discovery? Do we not continually prescribe for children, for protracted and serious complaints, who have never been vaccinated, who if they had been, would have been exhibited to the public as martyrs to vaccine blood-poisoning. Now, in all this, which is in no way exaggerated, and far from unusual, can vac-

Digitized by Google

cination be blamed, or should it be cried down, when after the trial of a century, it has been productive of incalculable benefits?

Solid and unmistakeable facts, the result of some years' experience, should alone be accepted as valuable and decisive on such a subject as this, and I base my statements upon the experience I have had for over thirty years as a public medical officer, which entitles, I think, my remarks to some consideration. During this period I have vaccinated and re-vaccinated over 9,400 cases, varying from the age of infancy to that of sixty, and in no one instance have I seen or known of any specific disease or symptoms arise from vaccination. This statement is the more valuable, because having completed thirty years of this period in Bray, I have been in a position of personally knowing and seeing what the results have been here.

Much of this work has been done before vaccination became compulsory upon the people, who, nevertheless, from the confidence placed in the operation, failed not to bring their children, which certainly would not have been the case, if all the evils we now have such clamour about had ever made their appearance. It is also, I think, most satisfactory to be able to state, that whilst several outbreaks of small-pox have occurred in various localities throughout Ireland, and in neighbouring districts, an epidemic of the disease has not, during this period, appeared in Bray, notwithstanding the uninterrupted intercourse existing with infected districts; the few cases which have occurred had not long been residing here, and were traceable to contagion received elsewhere. Now I think I may fairly claim on behalf of the value resulting from vaccination, that such an exemption in this populous district from so contagious a disease has resulted from the care and attention bestowed by other medical officers here, as well as by myself.

I have now before me the published official report of my friend, Dr. Abbott, during the seven years he acted as Chief Sanitary Commissioner in the Hyderabad districts, when nearly 300,000 successful cases of vaccination were performed under his superintendence, and he informs me "that he never saw or heard of any specific disease arising as the result of vaccination. In some cases inflammation appeared, such as would arise from any wound."

I would add a few words of advice to those who may be just commencing their duties as public vaccinators, and I congratulate them that the law has made it compulsory to have infants vaccinated at three months old. I never vaccinate until I am in every available manner satisfied as to the child's health, and that of both father and mother, which, from my knowledge of the people and their occupation, I do not find difficult. I never scar the arm, as I have often seen, and never make more than four short light incisions, and only in one place, and so avoid the severe inflammation and erysipelas often resulting. I never take lymph, except from an unmistakeably healthy child of known parents, and I take it on the seventh or early on the eighth day. I am careful as to the lancet used, and adhere to the square glass in preference to the tubes, by which I can effectually rub in the vaccine, and thus very seldom have to repeat the operation, whilst I secure a good mark.

I am sure, sir, the great importance connected with this subject, and its having been, very lately, so prominently brought before the public in two editorial articles by a Dublin journal, which has withheld the letter I offered for publication in reply, will plead as an excuse for making these few observations, which I do from a sense of duty, and with the hope that the matter will be more fully and more ably discussed by other members of the profession.

Yours, &c.,

THOS. L. WHISTLER, M.B. Trin. Coll. Dub., F.R.C.S.I.

[We would suggest that someone should supply an answer to the question whether any other virus than that of vaccinia can be or ever has been communicated by vaccination; and—if so—what the percentage of risk may be which any individual runs of being so infected? Is there really any conclusive evidence that a disease which did not already exist in the patient's system has ever been communicated along with the vaccine virus?—ED. M. P. & C.]

FOREIGN BODIES IN THE EAR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am much interested in the case of foreign bodies in the ear, recorded by Dr. Rawson in your issue of to-day; and I shall be much obliged if you will kindly insert the following observations on the subject.

The profession cannot be too grateful for any suggestion that assists its members in the prevention and cure of disease, and aural surgery is one of the branches of the healing art that is most in want of such assistance; but while fully admitting with Dr. Rawson that "a hairpin is an exceedingly simple little instrument for extracting foreign bodies from the external auditory meatus" (provided always that the operation is performed under a full illumination of the part, and this cannot be unless the hairpin is previously bent at an angle, so that the operator's own fingers do not get in his light), I must beg with all respect to doubt its utility, and I hope sincerely that no medical man will attempt to use it until he has first of all adopted the following method, which is the usual plan of all aural surgeons now-a-days, and has, after repeated efforts, failed in the attempt. In case a man does adopt the hairpin, it cannot be too strongly insisted upon that the illumination, by means of concave mirrors or otherwise, must be so good that the end of the instrument is never for one moment lost sight of during the whole operation.

The correct procedure is—1st. See the foreign body.

2nd. Syringe it out with lukewarm water, using a syringe that throws in a small jet, in order that the water may be able to insert itself behind the foreign body, and pulling the auricle slightly backwards and upwards, in order to straighten the canal. Try this with the patient lying on his side or on his back, as well as in the upright position.

3rd. Leave the foreign body where it is. Patients have been killed by attempts to remove foreign bodies which were otherwise perfectly harmless.

There has hardly been an aural surgeon of any note for the last half-century who has not protested against the use of any means but the syringe for the removal of foreign bodies from the meatus, except in very exceptional circumstances, and with very marked precautions. I might almost cite names at random to justify this remark. Kramer, Gruber, Toynbee, Hinton, are all eloquent upon the subject. However, not to go out of Ireland, I fancy you will find in one of your back numbers that Dr. Jones, of Cork, has epitomised all that can be said on the subject into a quotation from Hinton, "*I believe it may be laid down as a rule, that whenever an instrument will succeed, syringing will also succeed; and that, when proper syringing will not succeed, all instruments are full of danger.*"

In conclusion, I would observe that you will find the hairpin mentioned in Field's little treatise, 1876, p. 15:—"I can affirm that in nearly every case in which a patient has been brought to me with a foreign body in the ear, mischief has been caused by some anxious friend using a hairpin."

It is in the hope of preventing my medical brethren from being classed among such anxious friends, that I have trespassed so long upon your valuable space.

Yours, &c.,

JOHN B. STORY,

Surgeon to St. Mark's Ophthalmic Hospital.

Oct. 29, 1879.

THE DUBLIN INTRODUCTORIES

Have been in course of delivery during the past week, and nearly concluded. At the Royal College of Surgeons, Dr. Rose, Professor of Midwifery. At the University School, Dr. MacAlister, the newly-elected Professor of Anatomy and Chirurgery, and at the Catholic University, Dr. Nixon inaugurated the session. The Meath Hospital Session was commenced with an admirable address on the microphytic diseases of the blood. At the Richmond, Dr. B. J. MacDowel, at the Ledwich School, Dr. Nixon, at the Adelaide Hospital, Dr. Barton, and at St. Vincent's, Dr. Quinlan, delivered the introductories.

The Carmichael College threw open its new building in

Digitized by Google

a somewhat unfinished state, and signalised the occasion by an address from Dr. Gordon. We hope to give a brief *résumé* of each of these addresses in our next.

THE "College Club" of the Irish College of Surgeons had their annual dinner on Saturday last, which was made the occasion of a demonstration of welcome to Surgeon-Major Reynolds, V.C., who is at present in Dublin. Dr. Reynolds has already received the Honorary Fellowship of the Irish College of Physicians, and is to be made an LL.D. *hon. caus.* of the University of Dublin at the next commencements. The College of Surgeons is forbidden by its Charter to give its Hon. Fellowship, except for special eminence in the domain of Surgery, and could not, therefore, recognise in this way the heroic conduct of Dr. Reynolds at Rorke's Drift. The opportunity of the "Club" dinner was, therefore, availed of to entertain him fittingly. The President of the College, Dr. Mapother, held the chair, who was supported by Dr. McClintock, the Vice-President. The Albert Hall was crowded almost to inconvenience, and amongst the guests who accepted invitations were Lord O'Hagan, the Attorney-General Lord Massarene, the Lord Mayor, Mr. Gray, M.P., Mr. Brooks, M.P., Mr. Meldon, M.P., Dr. O'Leary, M.P., Mr. Rawlinson, C.B., the Director of the Catholic University, the Medical Commissioner of the Local General Board, Sir Robert Stewart, Sir George Owens, General Darby Griffiths, the President and Vice-President of the College of Physicians, and the leading members of the profession in Ireland. The name of Dr. Reynolds was associated with the toast of the guests, and he replied at length. The entertainment was diversified by a most excellent selection of music, and, on the whole, it may be pronounced a most successful gathering.

Medical News.

Royal College of Physicians of London.—The following gentlemen having undergone the required examination, were admitted members of this College on October 30th :—

Henderson, G. Courtenay, M.B. Lond., University College Hospital, London.
Smith, W. Wilberforce, M.D. Heidelberg, 2 Eastbourne Terrace, W.

The following were admitted Licentiates on October 30th :—

Ashby, Thomas Harry, M.B., Toronto, Cheltenham.
Ballance, Charles Alfred, Stanley House, Lower Clapton, E.
Bradford, Cordley, Smethwick, Birmingham.
Butler, Gamaliel Henry, Westminster Hospital, S.W.
Campbell, Robert Huntly, Gilling Rectory, York.
Delgado, Daniel Gelasio, 36 Palace Road, Lambeth, S.E.
Da Silva, Pascoal Manoel, Bombay, India.
Fischer, Carl, M.D., Würzburg, 62 Gower Street, W.C.
Fisher, Frederick Bazley, Queen's Road, Clapham Park, S.W.
Gofton, Joseph Edward, 22 Borough Road, North Shields.
Greenwood, F. Stowell, M.D., McGill, 149 Kennington Road, S.E.
Howell, Thomas Arthur Ives, Old Vicarage, Wandsworth, S.W.
Lithgow, Thomas George, Farnborough Station.
Robinson, George Somerville, 47 Claverton Terrace, S.W.
Sheild, Arthur Marmaduke, 88 Warwick Street, S.W.
Smith, Sydney, 54 Camden Road, N.W.
Weakley, Arthur, Forest Gate, E.
Wright, J. Wellington, M.D., McGill, 149 Kennington Road, S.E.

Royal College of Surgeons of England.—The following gentlemen were admitted Licentiates in Dental Surgery at a meeting of the Board of Examiners on October 28th :—

Davis, Harry, Kew.
Hammond, Gurnell Edward, Leinster Square.
Isard, William Alexander, Buenos Ayres.
Maggs, William Adolphus, Yeovil.
Major John Bernard, Penzance.

Faculty of Physicians and Surgeons of Glasgow.—The following gentlemen were admitted Licentiates of the Faculty during the October meetings of the Examiners :—

Brysen, Mungo, Glasgow.
Jones, Richard Thomas, L.S.A., Aberystwith
Morton, James C., Melbourne.
Ruddock, Thomas C., Heckmondwike.
Sutherland, Chas. J., L.R.C.P.Ed., South Shields.

Royal College of Physicians of Edinburgh and Faculty of Physicians and Surgeons of Glasgow.—The following gentlemen were admitted L.R.C.P.Ed. & L.F.P.S.Glas. at the October examinations in Glasgow :—

Andrews, Thomas M., Swansea.
Downes, Timothy C., Glasgow.
Holt, James, Newchurch.
Kelman, George, Glasgow.
Maconachie, James, Glasgow.
Nelis, William Francis, Glasgow.
Pullin, Frank B, Devon.
Stancer, Charles Ed., Glasgow.
Stilwell, Samuel D., M.D., Wigan.
Sutcliffe, Joseph, London.
Taylor, William, Durham.

Queen's University in Ireland.—The diploma in Midwifery was conferred on the following gentlemen during the October sittings of the Examiners :—

John Acheson, Henry K. Allport, James Barron, Robert Beattie, Henry Bingham, Thomas M. Corker, Joseph Crowley, W. E. Ashley Cummings, Samuel Dickey, Thomas Donovan, Hugh Greaney, John Hartnett, John Hosford, Gilbert Kirker, Henry M'Cormick, John M'Cormick, Samuel M. Malcomson, John Martin, Chas. A. Mitchell, Robert Mowbray, Myles William O'Reilly, Daniel Reardon, Thomas Simpson, John Smyth, William Smyth, Samuel Strahan, Alexander Suffern, Horace R. Townsend, T. Kennedy Wheeler, Sinclair White, David L. Williams, John Wilson.

The Pharmaceutical Society of Ireland.—The fourth annual meeting of this Society was held at the College of Physicians, Dublin, at 4 o'clock p.m., on October 6, Professor Tichborne, President, in the chair. Mr. Allen, jun., moved, in accordance with notice sent to the registrar a few days previously, that the voting papers of all members who had not paid their subscription for the preceding year be rejected, in accordance with rule 8. The President declined to put the motion—the effect of which, if carried, would be to reject the votes of the original members named in the Pharmacy Act; and he stated his opinion that those members were entitled to record their votes, and that the regulations relating to subscriptions applied to elected members only. If Mr. Allen, or any other member, thought his ruling was wrong, they could appeal to the Privy Council. The voting papers which had been returned, 57 in number, were laid on the table, and the President appointed Messrs. Bennett, Goodwin, and Minchin, as scrutineers, to count the votes. The statement of accounts showed a balance to credit of £81 in bank, and £307 in stock. The following were the votes obtained by each of the candidates: Aquilla Smith, M.D., 51; William Goulding, M.P., 34; John Thomas Holmes, 49; Sir George B. Owens, Kt., M.D., 43; Henry Bennett, 45; John Chilcott Charles Payne, 44; Henry Whitaker, M.R.C.S.E., 41. In addition Mr. Allen, jun., obtained 25 votes. The President hereupon declared the seven outgoing members of Council to have been re-elected. Professor Tichborne was re-elected President; Dr. Aquilla Smith, Vice-President; Mr. Hodgson, Treasurer; and Mr. Fennell, Registrar. The present Examiners, viz. :—In Latin, English, and Arithmetic, Dr. Collins; in Materia Medica and Botany, Dr. Walter G. Smith; in Pharmaceutical and General Chemistry, Mr. H. Draper; and in Practical Pharmacy, Dr. Robert Montgomery, were re-elected for one year. The meeting then proceeded to the consideration of—"The report of the Committee on the Pharmacy Act, Ireland, 1875." Amongst other changes it was resolved :—"That it is desirable that the Pharmaceutical Council should seek powers which will enable them to compel all persons who have their right to sell poisons preserved to them, to register their names." It was also resolved "That the Council be instructed to insert a clause to have an examination instituted for assistants to pharmaceutical chemists."

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber,'

Digitized by Google

"Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

MR. W. D. HEMMING, F.R.C.S.—If possible in our next.

INQUIRER.—*St. Luke* is a new "Clerical, Medical, and Art Review," price threepence weekly. You will find it referred to in our "Literary Notes" column.

DR. KNAPP.—Many thanks for the information.

MR. CROFT.—You should send your neighbour a copy of "Medical Etiquette;" the shilling so expended would, if appreciated according to its merits, be "heaping coals of fire upon his head."

THE "WELL-READ SWINDLER."

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I regret to see from your Correspondence columns that some eminent authors have been lately swindled by a literary sharper. If those gentlemen had read to any advantage a little book well known to schoolboys forty years ago—namely, "Æsop's Fables;" or had they remembered what happened in the second chapter of "Gil Blas"—the supper at the inn at Penaflor—my opinion is they would have been more "wide awake."

Yours, &c.,
A MEDICAL AUTHOR.

LUNG CONSOLIDATION AND FOREIGN HEALTH RESORTS.—We have received a number of letters referring to our last week's leader on "Residence Abroad in Lung Consolidation," which, owing to pressure on our space, we are compelled to hold over. We have evidently touched a blot in our present system.

OBSTETRICAL SOCIETY OF LONDON.—This evening (Wednesday), at 8 o'clock, Specimens: Solid Tumours of Ovaries, by Mr. C. J. Cullingworth; Parts from Tubal Gestation, by Dr. Godson. Papers: "On a New Method of Operation for Repair of the Female Perineum," by Mr. Lawson Tait; "On Expression of the Cord," by Dr. Matthews Duncan.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—You would oblige by informing me in your "Notices to Correspondents" what works would be the best to read on the following subjects for the membership of the College of Physicians—viz., comparative anatomy, histology, medical chemistry, principles of public health, and psychology.

Yours truly,
G. H. Y.

[There will not be an examination for membership of the King and Queen's College of Physicians before January, 1881, so that the text-books have not yet been arranged. As soon as they are we will publish their names.—ED.]

APPRECIATIVE.—It is at all times flattering to human vanity to be spoken well of and to be welcomed, and without egotism we hope we may lay claim to a fair share of this; we were, however, scarcely prepared to receive a letter from Dr. Warner, of Michigan, United States, stating that whilst travelling on the Continent this summer he came across a copy of the *Medical Press and Circular*, and was so impressed with its value and usefulness, that immediately on his return he determined to show his appreciation by asking us to place him on *the free list*, to mail him the journal regularly in future, and if we would further extend our kindness, he would like all the back numbers for this year that he might bind them. We feel flattered at our correspondent's desire to bind, but would suggest that he shows his appreciation in the more practical method adopted by so many of our readers in the States, of which the International Post Office Order authorities will be glad to furnish particulars.

THE "WELL-READ" SWINDLER.—In reference to the letter of "M.D.," which appeared in our last, Dr. H. D. Fowler, late Surgeon-Major of the 82nd Regiment, writes that his name has been made use of by the same man in an application for a loan to a brother officer.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I cut this from the *Manchester Guardian*, Oct. 11, embedded among the usual quack advertisements:—

MRS. C. MACKIE, Midwife and Ladies' Nurse-tender, Licentiate of King's and Queen's College of Physicians, Ireland, is open for Engagements, monthly or otherwise.—Apply to Colour Sergeant Mackie, 11th Regiment, Salford Barracks.

Can you inform me if the lady is a registered medical practitioner? If she is, and this is the way the profession is to be prostituted, the sooner the law is altered with respect to female practitioners the better.

I am, Sir, yours obediently,
A NON-ADVERTISING PRACTITIONER.

[Mrs. Mackie appears on the roll of "midwives and nurse-tenders" certified by the Irish College of Physicians; but she is not a "licentiate" in the usual acceptation of the word. We are not aware whether the College has any express regulation which forbids the use of the title of "licentiate" in this way. If not, we think it ought to have such a rule.—ED.]

VACANCIES.

Abbeyleix Union, Ballyroan Dispensary.—Medical Officer. Salary, £100, with fees, and £20 as Medical Officer of Health. Election, Nov. 18.

Ballieborough Union, Kingscourt Dispensary.—Medical Officer. Salary, £90, with fees, and £22 as Medical Officer of Health. Election, Nov. 11.

Dublin University.—Professorship of Zoology. Salary, £300.

Kent and Canterbury Hospital.—Assistant House Surgeon. Salary, £50, with board. Immediate application to the Secretary at the Hospital, Canterbury.

North Dublin Union Workhouse.—Medical Officer. Salary, £150.

Royal Free Hospital, London.—Assistant Surgeon on the Staff. Applications to the Secretary on or before Nov. 26. (See Advt.)

Warwick County Lunatic Asylum.—Junior Assistant Medical Officer. Salary, £100, with board. Immediate application to the Medical Superintendent at Hatton, Warwick.

APPOINTMENTS.

BARR, T., M.D., F.F.P.S.G., Lecturer on Aural Surgery at Anderson's College, Glasgow.

CALDER, Mr. M., a Resident Surgical Assistant to the Royal Infirmary, Glasgow.

DICK, W., M.B., L.R.C.S.Ed., a Resident Medical Assistant to the Royal Infirmary, Glasgow.

HARKNESS, T., M.B., C.M., a Resident Surgical Assistant to the Royal Infirmary, Glasgow.

HOWLETT, E. H., M.R.C.S., L.R.C.P., Assistant Demonstrator of Anatomy at the London Hospital Medical College.

HYBONS, Mr. E. A., a Resident Medical Assistant to the Royal Infirmary, Glasgow.

JACKSON, Mr. W., a Resident Surgical Assistant to the Royal Infirmary, Glasgow.

JONES, Mr. J. H., a Resident Medical Assistant to the Royal Infirmary, Glasgow.

KERIGAN, L., L.R.C.S.I., Medical Officer, Medical Officer of Health, &c., for the Castletown Geoghegan Dispensary District of the Mullingar Union, co. Westmeath.

KRAUSS, Dr. A. (of Nuremberg), Resident Medical Officer to the German Hospital, Dalston.

MAAKAY, Mr. A., a Resident Surgical Assistant to the Royal Infirmary, Glasgow.

MACKEY, G. I., M.B., L.R.C.S.I., Medical Officer to Bishop Foy's School, Waterford.

MCLACHLAN, R., M.B., C.M., a Resident Surgical Assistant to the Royal Infirmary, Glasgow.

MCWATT, J., M.B., C.M., a Resident Medical Assistant to the Royal Infirmary, Glasgow.

MAPOTHER, E. D., M.D., F.R.C.S.I., Consulting Surgeon to St. Joseph's Hospital for Children, Dublin.

PATTERSON, J., M.B., L.R.C.S.I., Certifying Factory Surgeon for the District of Ramelton, co. Donegal.

QUINLAN, D., L.R.C.S.Ed., L.R.C.P.Ed., Medical Officer to the Ballyhooly Dispensary, Fermoy Union, and Medical Attendant to the Royal Irish Constabulary.

SIMON, E. M., B.A., M.B., M.R.C.P., Assistant Physician to the General Hospital, Birmingham.

WITHAM, Mr. A., a Resident Medical Assistant to the Royal Infirmary, Glasgow.

Births.

BAILEY.—On Oct. 30, at Hopesay, Salop, the wife of J. Battersby Bailey, M.D. Q.U.I., of a son.

CHETWOOD.—On Oct. 30, at 10 King Street, Finsbury, London, E.C., the wife of William Chetwood, M.R.C.S., of a daughter.

DAVIS.—On Oct. 28, Newport, co. Mayo, the wife of Hugh A. Davis, M.D., of a son.

JENINGS.—On Oct. 29, and 28 Rathmines Road, Dublin, the wife of Ulick A. Jenings, Surgeon-Major A.M.D., of a son.

KELLY.—On Oct. 26, at Mullingar, co. Westmeath, the wife of Joseph Dillon Kelly, L.R.C.S.I., of a son.

OLDMAN.—On Oct. 29, at Bletchingly, Surrey, the wife of C. E. Oldman, M.D. Cantab., of a son.

Marriages.

LODGE—DAVIS.—On Oct. 29, at St. Pancras Church, London, Thomas Arthur Lodge, Esq., of North Warnboro', to Alice, daughter of Dr. H. P. Davis, of 1 Euston Square London.

WHITELAW—SPENCE.—On Oct. 30, at Huntly, Wm. Whitelaw, M.D., of Cupar, to Isabella, third daughter of A. Spence, Esq., of Huntly, N.B.

Deaths.

BOWKER.—On Oct. 4, at Appleby-Magna, Robert Stanser Bowker M.R.C.S.E., aged 64.

COLLEDGE.—On Oct. 28, at Cheltenham, T. R. Colledge, M.D., F.R.S.Ed., aged 83, for 42 years Medical Missionary in China.

DAVIDSON.—On Oct. 31, at Shaftesbury House, Bayswater, W., Thos. Davidson, M.D., aged 77.

DONNELLY.—On Oct. 23, at Auburn, Malahide, co. Dublin, William Donnelly, Esq., C.B., late Registrar-General for Ireland, aged 75.

GOODDAY.—On Oct. 19, at Werter Road, Putney, Horatio Goodday, M.D., aged 72.

MASSINGHAM.—On Oct. 26, Joseph Ebenezer Massingham, M.R.C.S.E., of Green Street, Victoria Park, E., aged 63.

MOONEY.—On Oct. 21, Dungannon, co. Tyrone, David Mooney, M.D., aged 63.

PERRIN.—On Oct. 24, at Southampton, Alfred Charles Perrin, M.R.C.S., aged 27.

RUSSELL.—On Oct. 24, at Doncaster, William Cook Russell, F.R.C.S.E., aged 69.

WEIGHT.—On Oct. 20, at Wokingham, Berks, Ed. Weight, M.R.C.S.E., aged 74.

WRIGHT.—On Oct. 21, at Hounsfield Road, Sheffield, James F. Wright, L.S.A.L., aged 79.

IRISH POOR-LAW INTELLIGENCE.

THE RESPONSIBILITIES OF IRISH SANITARY OFFICERS.

We published last we ek a report of proceedings of the Limerick urban sanitary authority, which recorded that Dr. Barry, the medical superintendent officer of health, had repeatedly recommended the purchase of a disinfecting chamber, which the authority had has often refused to buy. On this occasion one of the members—a person named Hastings—took occasion not only to state his own worthless opinion as to the remedy for zymotic disease, but to insult Dr. Barry in his absence, and threaten him with vengeance if he persisted in reporting the neglect of sanitation in the city.

The episode is worth notice as an illustration of the sort of persons entrusted with Irish sanitation, and the sort of humiliation and annoyance to which medical sanitary officers are subjected at the hands of their unmannerly and ignorant masters. Another example of the responsibility which those officers have to endure is found in the proceedings of the Parsonstown Guardians to Dr. Wallace. That gentleman in the discharge of his duty reported to the Registrar-General the existence of sanitary defects in his district. The Registrar-General prints his report in the appendix to the quarterly returns, and the Local Government Board sends the extract to the Parsonstown Guardians in order that they may exact condign punishment upon Dr. Wallace for having been insubordinate enough to smell the stenches and see the filth of that town. Thereupon the following letter is addressed to Dr. Wallace by the board of guardians :—

Sir,—I have been directed by the board of guardians to request that you will be so good as to furnish the guardians with an explanation of the statement made by you in a recent report to the Registrar-General, in which you, Dr. Wallace, Registrar of Births, &c., and Medical Officer of Health, Riverstown District, among other observations, wrote: "I have ceased to meddle with bad houses, and the other grave defects of my district, as I only get into hot water with the members of the sanitary authority by doing so."

The Local Government Board, in a communication dated 24th inst., have called the guardians' attention to this matter.

I am, sir, yours, &c.,
Henry Dally, Clerk of the Union.

Parsonstown Union, 28th October, 1879.

The following is Dr. Wallace's reply :—

TO THE CLERK OF THE PARSONSTOWN BOARD OF GUARDIANS.

Sir,—Referring to your communication of the 28th October, I beg to say that there is a space in the quarterly return which I make, as Registrar, for reports on the sanitary condition of my district, and I consider such reports as privileged communications.

I have no objection, however, to give my reasons for the statement I made. On the first occasion on which I called attention to the wretched condition of some cabins in the Ballea bog, and offered to point out how they might be improved, I have reason to believe that the question was asked "Does Dr. Wallace suppose the guardians are going to build houses for the poor?" On the last occasion of my reporting on the same subject, the member of the board who is best acquainted with the condition of these houses met me in the street, and endeavoured, in what seemed to me a very unseemly way, to force his opinion on me that these wretched hovels, composed of bog, mould, and straw, with floors in which the foot sinks, were fit habitations for human beings.

I believe I do the Sanitary Authority no wrong when I say that if I were to propose sanitary improvements in the district that would cost £50 or £100, it would meet with the most violent opposition; in fact, would not be listened to. I may add that I believe it is a fair conclusion from the recent decision of the board to reduce the sanitary salaries by one-half, and the discussion which took place at the time, that it is the opinion of a large majority of the board that the duties of the medical officer of health are perfectly unnecessary, and that if we were satisfied to take no pay the Sanitary Authority would be periectly satisfied that we should do no work. Taking all these facts into consideration, I think I am perfectly justified in making the observations I did, which just amounts to this, that the guardians are strongly opposed to any outlay on sanitary matters.

Yours, &c.,
Alex. Wallace.

29th October, 1879.

As we are not liable to be dismissed or snubbed either by the guardians or the Local Government Board, we can afford to speak plainly, and we assert that not only Dr. Wallace, but a great majority of the medical officers of health for Ireland, have "ceased to meddle" with "grave defects" within their districts for no other reason than they "only get into hot water for doing so;" and because they felt that they need expect little support or protection from the Local Government Board in the fearless discharge of their duty.

THE NEGLECTED LUNATICS (IRELAND) BILL.

We gave last week a full abstract of Lord O'Hagan's Bill, which was introduced into the House of Lords last year, and will, no doubt, be brought forward in the early days of next session. The first section of that Bill extends to Ireland the operation of the English law for the guardianship, examination and certifying of harmless

Digitized by Google

lunatics. The sections of the English Lunacy Act thus applied to Ireland are as follows :—

66. Every pauper lunatic not in an asylum, or a hospital registered or a house licensed for the reception of lunatics, shall be visited once in every quarter of a year by the medical officer of or for the parish or union or district of a parish or union in which such lunatic is resident ; and such medical officer shall be paid the sum of two shillings and sixpence for each such quarterly visit to any pauper not being in a workhouse, which sum shall be paid by the same persons, and be charged to the same account as the relief of such pauper ; and within seven days after the end of every such quarter such medical officer shall prepare and sign a list according to the form in the schedule (E.) to this Act of all such lunatics, and shall state therein whether in the opinion of such medical officer all or any of such lunatics are or are not properly taken care of, and may or may not properly remain out of an asylum, and such medical officer shall within the time aforesaid deliver or send such list to the clerk to the guardians of such parish or union, and such clerk receiving any such list as aforesaid shall, within three days after, transfer the same to the Commissioners in Lunacy, and every such medical officer or clerk failing to comply with this enactment shall for every such offence forfeit any sum not exceeding twenty pounds nor under two pounds.

67. Every medical officer of a union who shall have knowledge that any pauper resident within the district of such medical officer, is or is deemed to be a lunatic, and a proper person to be sent to an asylum, shall within three days after obtaining such knowledge give notice thereof in writing to a relieving officer of such parish, and every relieving officer who shall have knowledge, either by such notice or otherwise, that any pauper resident in such parish is or is deemed to be a lunatic, and a proper person to be sent to an asylum, shall within three days after obtaining such knowledge give notice thereof to some justice of the county or borough within which such parish is situate ; and thereupon the said justice shall, by an order under his hand and seal, require such relieving officer to bring such pauper before him, or some other justice within three days from the time of such notice ; and the said justice before whom such pauper shall be brought shall call to his assistance a physician, surgeon, or apothecary, and examine such person ; and if such physician, surgeon, or apothecary shall sign a certificate with respect to such pauper, according to the form in schedule (F.) No. 3 to this Act annexed, and such justice be satisfied, upon view, or personal examination of such pauper or other proof, that such pauper is a lunatic, and a proper person to be taken charge of and detained under care and treatment, he shall, by an order under his hand direct such pauper to be received into such asylum as hereinafter mentioned, and such relieving officer shall immediately convey or cause the said lunatic to be conveyed to such asylum, and such lunatic shall be received and detained therein.

68. Every constable of any parish, and every relieving officer who shall have knowledge that any person wandering at large within such parish (whether or not such person be a pauper) is deemed to be a lunatic, shall immediately apprehend and take or cause such person to be apprehended and taken before a justice ; and every constable of any parish, and every relieving officer, who shall have knowledge that any person in such parish not a pauper and not wandering at large as aforesaid is deemed to be a lunatic, and is not under proper care and control, or is cruelly treated or neglected by any relative or other person having the care or charge of him, shall, within three days after obtaining such knowledge, give information thereof upon oath to a justice, and such justice shall, either himself visit and examine such person and make inquiry into the matters so appearing upon such information, or by an order under his hand and seal direct and authorise some physician, surgeon, or apotheaary to visit and examine such person, and make such inquiry, and to report in writing to such justice his opinion thereupon ; and in case that such person is a lunatic, and is not under proper care and control, or is cruelly treated or neglected, it shall be lawful for such justice to require any constable of the parish or place, or any relieving officer, to bring him before any two justices of the same county ; and the justice before whom any such person is brought shall call to his or their assistance a physician, surgeon, or apothecary, and shall examine such person, and make such inquiry relative to such person as he or they shall deem necessary ; and it shall be lawful for the said justice or justices, by an order under his or their hand and seal or hands and seals, to direct such person to be received into such asylum as hereinafter mentioned.

70. If any medical officer of any union omit for more than three days after obtaining knowledge of any pauper resident within his district, being or being deemed to be lunatic, and a proper person to be sent to an asylum, to give such notice thereof as is hereinbefore required ; such medical officer shall for every such offence forfeit any sum not exceeding ten pounds.

71. If any relieving officer, by this Act required to convey any person to any asylum, refuse or wilfully neglect to execute such order with all reasonable expedition, he shall for every such offence forfeit any sum not exceeding ten pounds.

72. Orders of justices, &c., may extend to authorise reception into hospitals or licensed houses, but lunatics to be always sent to asylums, if circumstances permit.

78. Pauper lunatics not to be received into any other than the county or borough asylum without endorsement of order by a visitor, provided always that no lunatic being a pauper shall be received under any order made by virtue of this Act into any asylum, other than an asylum belonging wholly or in part to the county or borough in which the parish or place from which such lunatic is sent, or the parish in which he is adjudged to be settled, is situate, except there be a subsisting contract for the reception of lunatics of such county or borough therein, or such borough otherwise contributes to such asylum, unless such order be endorsed by a visitor of such asylum ; and it shall not be compulsory on the superintendent of any registered hospital or the proprietor of any licensed house to receive any lunatic under any such order, except in pursuance of any subsisting contract.

81. Visitors may discharge a lunatic on the undertaking of a relative or friend ; where application is made to the committee of visitors of any asylum by any relative or friend of a pauper lunatic confined therein, requiring that he may be delivered over to the custody and care of such relative or friend, it shall be lawful for any two of the visitors aforesaid, if they think fit, and upon the undertaking in writing of such relative or friend to the satisfaction of such visitors that such lunatic shall be no longer chargeable to any union, parish, or county, and shall be properly taken care of, and shall be prevented from doing injury to himself or others, to discharge such lunatic.

It will be observed that the effect of these clauses is to provide—*a*. That all lunatics who are at large shall be periodically inspected by the dispensary medical officer, and returns of their condition made to the guardians, for which duty the officer is to receive a fee of 2s. 6d. a quarter.

b. That all medical officers, relieving officers, &c., shall be bound to give notice of the state of any person whom they may find to be insane, and that the person so reported shall be examined and certified in the same manner as dangerous lunatics are now dealt with. For the remuneration of the medical officer for performance of this duty the Bill provides in the same terms as the present Dangerous Lunatics Act.

A SPECIMEN OF IRISH SANITATION.

NAAS UNION.

THE Local Government Board forwarded copy of a report on the sanitary condition of the town of Naas, which has been forwarded to them by Dr. Smyth, medical officer of Naas and Carragh.

(Copy.)

Appendix to Quarterly Report—Naas.

"The town of Naas still continues to be extremely deficient in proper sanitary arrangements. For many years and for many times in each year, the matter has been pressed on the attention of the sanitary board, and has been over and over again discussed in almost every detail. The sanitary authority have spent the past six years and have not yet arrived at any intelligent conclusion. At present they have it under consideration to establish a system of private cesspools at the rear of those houses provided with water-closets, and have seriously and formally asked the town commissioners whether this solution of the sanitary difficulty would not meet their approval. It is now nearly five years since the sewers of the town, or rather what passes for sewers, were opened up, carefully examined, and reported upon by the county surveyor. The disclosure then made was a truly shocking one, and disgraceful to a civilised community. Those drains, some of them of enormous capacity, were shown to be simply underground channels which had been converted into elongated cesspools; one of them actually had its gradient reversed—in other words it ran up a hill (a laugh), while the principal sewer in the main street is a vast *cul-de-sac*, from which nearly one hundred cartloads of sewage were removed.

"Regarding the other sanitary requirements of the town, matters are, if possible, in a more unsatisfactory and dangerous condition. There are between 300 and 400 houses in the town which have no latrines. In addition to these there are about fifty other houses still worse, because they have not only no latrines, but they have no rear accommodation at all, and the refuse from them must be deposited in the street. Indeed, I may state that the whole town presents a condition of sanitary neglect which imperatively calls for practical action."

Mr. Tracy—I don't see the town of Naas is kept so shockingly dirty at all.

Mr. Mansfield said from his experience of other country towns he thought Naas would compare favourably with any in Ireland.

Mr. de Burgh drafted a form of reply to the letter, which was adopted. It was to the effect that the guardians were most anxious to carry out a system of drainage for the town, and were doing everything in their power to expedite the matter.

THE SANITARY COMMISSION.

TO THE EDITOR OF THE "MORNING AND EVENING MAIL."

Dublin, October 14, 1879.

SIR,—The Sanitary Commissioners now sitting have stated that the inquiry will close next week.

I have been an attentive reader of the daily proceedings, and on a number of occasions have attended and listened to the evidence brought forward, but on no occasion that I am aware of has the name of any one of the sixteen medical officers of health for the city of Dublin, who are statutable officers, that is, officers imperative to the Public Health Act, independent, and not servants of the Public Health Committee, been mentioned either by Commissioners, Public Health Committee, or Sanitary Association. One, indeed, Dr. C. H. Moore, came forward and read a number of complaints of nuisances forwarded to him by persons suffering from them, but he was soon shut up and not a single pertinent question asked of him on any side.

Dr. Cameron, the superintendent medical officer of health, was examined, and as far as his evidence went it was very good, but he holds his office at the will and pleasure of the Public Health Committee, and is answerable to them alone.

On behalf of the citizens at large, therefore, I would ask you to use your influence to have the medical officers of health called and examined.

I do not press you to publish this letter, but I do ask you as a leader of public opinion to express in your columns a decided opinion that the officers who are depended on to do the sanitary work, and who ought to know something of the sanitary condition of the city, should not be altogether left in the background on this the only (probably) occasion when we shall have a chance of learning what are the causes of our excessive mortality, and what are the fittest steps to be taken by us towards reducing it.

For obvious reasons I can but sign myself,

Your obedient servant,

PHYSICIAN.

A DISREPUTABLE HOAX.

THE Local Government Board lately forwarded to the hon. secretary of the dispensary committee of Sligo a copy of a letter which they had received, purporting to be written by Dr. Palmer, complaining of Dr. Denning as being an inefficient and unqualified apothecary. Dr. Palmer, it appears, never wrote such a letter, and holds the very opposite opinion regarding Dr. Denning. The letter is, it seems, a forgery.

DISPENSARY ELECTION—THE CASTING VOTE.

THE Local Government Board have communicated to the Ballyroan dispensary committee their decision respecting the recent election of a medical officer for the district. At the recent election Mr. Pepper, who it is alleged was struck off the committee some time ago, attended and voted for Dr. Coyne. Mr. Pepper's vote made the numbers for the two candidates equal, and the chairman gave a casting vote for Dr. Coyne, whom he then declared to have been duly elected. The Local Government Board point out that the chairman has no casting vote, and that if Mr. Pepper is not a member of the committee there would appear to be a majority for the other candidate.

CARRICKMACROSS UNION.

SALARIES UNDER THE PUBLIC HEALTH ACT.

THE consideration of the letter received from the Local Government Board recently, in reference to the proposed reduction of the doctors' salaries under the Public Health Act, from what they had as sanitary officers, £15 to £10, was taken up.

Mr. Phelan said to take a practical view of the matter he didn't see how they could resist the L. G. B. They seem determined not to allow the reduction, and I think in order to prevent them carrying out their threat of increasing the salaries we should yield, but under protest.

The Chairman read that part of the letter in which they stated that should the guardians adhere to their resolution they would issue a sealed order fixing the salaries of the doctors at sums commensurate with the duties which they would now be called upon to perform.

Mr. Phelan—It's an open threat. They possess arbitrary power and they mean to use it. I have prepared a short reply to their letter and I will move that it be adopted.

Mr. Phelan then moved—

"That as the guardians have to submit to the arbitrary authority of the Local Government Board in this matter by their threat to increase the salaries, they do so under strong protest, which they desire publicly to record."

The motion was agreed to.

QUARTERLY RETURN OF BIRTHS AND DEATHS.

DURING the quarter ended 30th September last, there were registered in the 799 registrars' districts in Ireland 32,918 births—a number equal to 24·6 in every 1,000 of the estimated population—and 20·423 deaths, representing an annual mortality of 15·2 per 1,000.

In England last quarter, the birth-rate represented was 34·4, and the mortality 16·4 per 1,000.

The birth-rate in Ireland was 0·1 under the average of the corresponding quarter of the five years 1874—78, the death-rate was 0·7 in excess of the average for the same period. The principal zymotic diseases caused fewer deaths than at the corresponding period of last year, the rate of mortality from these affections being 37·2 of the population, against 51·1 for the third quarter of 1878. The slight increase in the mortality from all causes may be mainly attributed to the continuance of the inclement weather, and possibly in some degree to the increase of poverty, as shown by the return of the number of persons receiving relief, which shows a considerable excess over the average.

BIRTHS.

The births during the quarter ended 30th September last amounted to 32,918—24·6 per 1,000 of the population. The average ratio of births registered during the corresponding quarter of the last five years was 24·7 per 1,000.

The highest county birth-rate is 30·9 per 1,000 for Dublin, and the lowest 20·5, for Fermanagh.

DEATHS.

The deaths registered during the quarter amount to 20,423, an annual ratio of 15·2 per 1,000 of the population, against an average rate of 14·5 for the corresponding quarter of the five years 1874—78.

The death-rate in Leinster was 17·4 per 1,000, in Munster 14·9, in Ulster 14·9, and in Connaught 13·1.

The county death-rates range from 11·6 per 1,000 in Sligo to 22·8 per 1,000 in Dublin. Between these rates the five highest are Carlow, 17·9; Armagh, 16·6; Westmeath, 16·4; Antrim, 16·3; and Waterford, 16·0; and the five lowest Fermanagh, 12·3; Donegal, Wicklow, and Longford, each 12·6; and Leitrim, 13·0 per 1,000.

HEALTH OF THE PEOPLE.

The public health has materially improved during the past quarter, as compared with the first two quarters of the present year, but nevertheless it cannot be considered very satisfactory, inasmuch as the death-rate is above the average, and severe epidemics have prevailed in some districts, for example:—Small-pox in Dublin and its suburbs, scarlatina in Cork, whooping-cough in Belfast, and measles in some portions of the South-Western division of Ireland.

During the same period the death-rate in England was 16·4, against an average of 20·2, showing a decrease of 3·8 upon the the average death-rate of England in the third quarter. In the second quarter of the present year the English death-rate was slightly below the average, and in spite of the extremely severe weather which prevailed during the first quarter it was but 1·1 above the average. In Ireland during the first quarter it was 3·2 above, in the second 1·9 above, and again, in the third (as already stated), 0·7 above the average. It would thus appear that during the present year the public health in Ireland has been becoming worse, while in the sister country it has been improving, an entirely unsatisfactory state of things, which cannot be accounted for by the weather, which was not more unfavourable in Ireland than that in England, or by the state of trade, which does not appear to have had as great an affect in Ireland as in England.

Special attention is directed to the Registrars' notes, to be found at pages 127-133. They contain much valuable information as to the sanitary condition of the country, and locally prevailing diseases. It would be well for those who take an interest in the welfare of the districts in which they reside to give special attention to the defects pointed out in the Registrars' notes. These notes possess a peculiar value, as they are furnished by gentlemen who occupy not only the position of Registrars, but also those of Dispensary Medical Officers and Medical Officers of Health, under the Public Health Acts, and who have, therefore, special opportunities of becoming acquainted with the sanitary defects and requirements of their respective districts.

Diseases.—The number of deaths returned by the Registrars as having resulted from the principal zymotic diseases* is 1,996, or 9·8 per cent. of the total deaths registered, and equal to 37·2 in every 100,000 of the population. This number is 740 under the deaths from the same causes in the corresponding quarter of 1878, and 265 under the average mortality for the third quarter of the three years 1876 to 1878.

Small-Pox.—The deaths from small-pox, which in the first quarter amounted to 334, and in the second quarter to 153, further diminished to 84 during the last quarter; all of these except 4 (1 in Belfast, 2 in Ballymena, and 1 in Loughrea), occurred in the province of Leinster; the greater number occurred in the county and city of Dublin, amounting to 72.

Measles.—The deaths from measles numbered only 104, being the smallest number registered in any quarter during the past two years. In the second quarter of this year the number was 183, or 79 more than in the past quarter; the number for the corresponding quarter of last year was 309.

Scarlet Fever.—This disease caused 309 deaths, as compared with 307 in the second quarter. This disease has been very prevalent in the City of Cork during the past quarter, the first cases having occurred towards the end of the preceding quarter. In Ulster the deaths from scarlatina numbered 75, as compared with 115 in the preceding quarter.

Diphtheria.—Only 48 deaths from this disease were registered during the quarter. These were very generally distributed through the country. There were 15 in the province of Leinster, 10 of which were in the county and city of Dublin, 5 within the Dublin Registration District. In Ulster there were 19 deaths from this disease, which were generally distributed through the province; four of these occurred in the Ballymena Union. There were 7 deaths from this disease in each of the provinces of Munster and Connaught.

Whooping-cough.—There were 375 deaths from this disease, as compared with 416 in the second quarter of this year, 521 in the third quarter of the year 1878, and 355 in the third quarter of the year 1877. It would thus appear that the epidemic of whooping-cough, which has prevailed in some parts of the country during the past year is abating.

Fever.—There were fewer deaths from fever in the past than in the preceding quarter, the numbers being 651 and 774 respectively. The deaths, however, were in excess of those of the corresponding quarters of 1877 and 1878, when they amounted to 620 and 621 respectively.

Diarrhœa.—There were only 417 deaths from diarrhœa registered during the quarter, being 291 lower than the number registered for the corresponding quarter of the year 1878. This slight prevalence of diarrhœa is mainly attributable to the low temperature and excessive rainfall which prevailed during the quarter.

Simple Cholera.—Only 8 deaths were referrible to this disease.

PSYCHOLOGY AND THE NERVOUS SYSTEM.

By J. HUGHLINGS-JACKSON, M.D., F.R.S.,

Physician to the National Hospital for the Epileptic and Paralysed, and to the London Hospital.

(Continued from page 385.)

We must now consider the two terms Objective and Subjective. They are used variously in medical writings.

Sometimes the term subjective is used for psychical states, and the term objective for the correlative physical states. Under this use of the terms colour is subjective, the correlative discharge in the visual centres is objective.

Occasionally, however, the term subjective is used for a psychical state when the corresponding physical changes are centrally initiated, and the term objective for a psychical state when the corresponding changes in the centre are peripherally initiated. Under this use of the term when we think of colour (coloured thing) there is a subjective state; when we see a colour there is an objective state. This use of the two terms is out of harmony with the first-mentioned use of them, for colour is always a psychical state (a state of our minds), and there are always along with it nervous states. So that if the first use of the two terms is correct, we should say that in thinking of colour there is a subjective along with an objective state, and that in seeing a colour there are also the two correlative states. Indeed, it would almost seem to be held by some that when we think of a thing (ideation) there is a psychical change only, and that when we see it (perception) there is a physical change only. In each case there is both. The difference betwixt the two is only one of degree. The psychical state in the former is faint, in the latter vivid. The physical state during the former is a slight nervous discharge, in the latter a strong nervous discharge.

Obviously it matters not for the psychical nature of what goes on whether we are looking at blazing crimson, or have intense red "balls of fire" before our eyes at the onset of an epileptic or epileptiform seizure, or are thinking, however faintly and transitorily, of the least vivid red we saw years ago. There must be corresponding physical conditions, there must be nervous discharges of differing strength, during the three psychical states.

Let us take a medical observation. Some epileptics have at the onset of their paroxysms, a strong stench in the nose. This is often called a subjective sensation. If subjective be used as a term for psychical states, the expression is correct, except that it is tautological, for all sensations are psychical states. But the expression, subjective sensation of smell, is sometimes used in contrast to a smell initiated by some substance placed under the nose; the latter is then called an objective sensation of smell. But if objective applies to nervous states, the expression "objective sensation," is absurd. (*a*) Whether a smell arises during slight discharges in the nervous centre, as when we think of some odour, or during excessive central discharges in some cases of epilepsy, or from central changes roused by odorous particles striking on the olfactory periphery, it is still psychical, and in each case the smell is a different thing from the correlative discharges in the olfactory centre, a purely physical process which must occur in each case.

I hope no one will suppose that I imagine myself to be capable of declaring the right way in which these two venerable terms should be used. I am only about to state the way in which I shall use them. For the present I speak very briefly.

Much of what follows is hypothetical. I should not venture on the inquiry were it not that I think we must study delirium, epilepsy, &c., on a deeper basis. The hypothesis stated most generally is that mental states are

(*a*) In some of the cases of epilepsy in which the paroxysm is heralded in by a strong stench in the nose, there is loss of smell; as the patient puts it, he never smells anything outside him, but is worried by smells in his nose. It is just as some blind patients are worried by vivid colours. These cases are sometimes described as loss of objective sensation, with retention of subjective sensation of smell.

Digitized by Google

always double, and double in a particular way to be indicated by the two terms I am about to define.

I use them both as psychical terms. A subjective state is one which is the psychical side of what is physically the influence of the environment on the organism. The fuller definition is to say that a subjective state is the psychical side, not only of the effect of the present environment on us, but of that in relation to the whole of what we are from past organisations of such effects, individually and racially. Subjective states are in their totality subject consciousness.

On the other hand, the term objective is used for the psychical side of the present reaction of the organism on the environment, and for that in relation to all possibilities of reaction, which we have organised individually and racially. Objective states are in their totality object consciousness.

The correspondence of the organism with the environment is duplex; the environment acts on the organism, and the organism reacts on the environment; "we," physically being all that has been organised during the two parts of the correspondence, racially and individually.

It is not meant, of course, that there is a case of simple and complete reflex action, but often of exceedingly compound and incomplete reflex action. It may be, for example, that the whole organism is engaged in those correspondences in which the highest nervous centres are ultimately concerned during discharge of which centres, will, memory, and emotion are displayed.

So, then, the two terms are not used as psychically corresponding to what are materially (1) organism and (2) environment, but as corresponding to (1) organism as affected by, and (2) organism as reacting on, the environment. As psychical states both are states of our minds; the two corresponding physical states are states of our bodies. The whole double process is in us—in our minds and in our bodies. How it is that we have got the notion of there being two separate things in relation, organism and environment, I do not inquire.

Nothing justifies us in using the term subjective at one time as a name for psychical states, and thus in contrast to states of the nervous system and rest of the organism, which latter states are then called objective; and at another time for mind, in contrast to the environment, which latter is then called objective.

The division just made is plainly too abrupt: there is no such absolute chopping in two. Let us approach the consideration of this admission by first trying to show what we do *not* mean by the two terms, subjective and objective.

The difference betwixt ideation and perception is not what we mean by the difference betwixt subjectivity and objectivity. Let us see how ideation and perception differ.

We said that the difference betwixt thinking of a thing, ideation, and seeing it, perception, is in faintness and vividness. But there is a further difference; in the former an image is feebly referred to the environment; in the latter strongly so referred. But in each case it is so referred, and is, therefore, objective. Whether I think of a ball, or see one, that ball is seen or thought of (ideally seen) in the environment, as not me; in the former there is a faint image, feebly referred to the environment, and in the latter a vivid image, strongly referred to the environment; so that both ideation and perception are objective; there is objectivisation in different degrees.

Of course, neither the faint nor the vivid image is in the material environment; it is in us as much as the pain of a pin-prick is in us. It is manifestly so of visual images in dreaming, and strikingly so of images occurring in delirium of the blind. A patient of mine, several years absolutely blind, becoming insane, would "see" people in front of her, and once took the poker to strike one of them. She referred some images to the environment, and by the same process as healthy people do. These images were in her. The so-called material environment starts in us the subjective process, which is followed by the objective process, and it is the images constituting the latter which we call the environment (each person's environment). What the so-called material environment is we know not. And when we think of any images the process is more obviously the same fundamentally, as in delirium; there is excitation of nervous arrangements representing experiencesof former actions of the so-called material environment on us. This is followed by excitations of other nervous arrangements corresponding to images referred to and constituting the environment which images are hallucinations, true forus, as the poor girl's were true for her. We can see only in the sense of having images that objects can provoke in us; the Esquimaux could not understand that glass was not ice; it was perceived as ice, because it could in them develope nothing else than that image. Why images in us are taken to be in, or to be part of, the environment I do not inquire. Let us look at the anatomico-physiological side of the difference betwixt ideation and perception.

Physiologically there is in each case a discharge of parts of the highest centres, but slight and strong, corresponding to faint and vivid images. This difference in strength of discharge of highest centres leads to a further difference. In perception the lower centres are engaged also, for in that case the discharge of the highest centres being strong, overcomes the resistance of these lower centres, and puts them in action, and ultimately peripheral parts. To return for a moment to the psychical side, ideation does not pass into perception by insensible degrees; insensible degrees are equivalent to no degrees; there would, indeed, be no such contrasted things as ideation and perception were this so. The resistance offered by the lower centres, to discharges beginning in the highest, is the physical side of effort, the basis of our knowledge of the difference betwixt ideation and perception. When it is not overcome there is ideation, when it is overcome ideation passes into perception.

The popular notion is that we see or perceive an object first and then think of it, or have an idea of it; we think of it first and then see it, or rather the image first rises up in us, and is then projected externally. A description of the correlative physical process is not an explanation of this external projection. Nor would it be an explanation if we were able to give all details of the physical process correctly.

So, then, we say that ideation and perception are doubly compound degrees of objective activity. Now for the subjective stage which precedes ideation, followed or not followed by perception.

Before I can have an image of, or think of, a ball, as in the environment, faintly or vividly, that image must have arisen in my mind. It is this prior process subconsciously preceding either ideation or perception, which is in this book to be called subjective. We have stated part of this in an earlier paragraph. Of course, the image referred to the environment is in all cases in, or is part of, our mind; but the image must first arise as a survival during the end of a conflict of many or of the whole of our already organised experiences before we can have it as in the environment. It is this image, or its similar, which is at once the end of the subjective and the beginning of the objective stage. Physically the changes (subjectively) are periphero-central, (objectively) centro-peripheral. This is re-stating that subjective activity corresponds to what is physically the effect of the environment on us, and that objective activity corresponds to what is physically the reaction of the organism on the environment. Periphero-central changes may be either strong discharges of centres, determined by something acting upon the related periphery, or slight central discharges of centres, which once were acted on by a related part of the periphery, and thus represent it. Centro-peripheral changes are strong discharges of centres which move parts of the periphery, or slight discharges which give the idea of its moving them, or give us results equivalent to moving them.

Digitized by Google

Possibly the reader may hold that the prior process is not subconscious, but unconscious, *i.e.*, that there is prior nervous activivity which has no attendant consciousness, but that it leads to modifications of the sub-strata of object consciousness which are attended by consciousness. At all events, before any one sees an object, that object must have roused an image in him, and all he sees is what is aroused by that object in him.

There is no "faculty" of perception we cannot see or think of what we like; we only see images, or better, have images objectively of subjective origin—that is, which (1) presented objects rouse in us, or (2) images risen in us from a conflict of many past organised images. In both cases the subjective process is essentially one. The objective process, whether in the degree of perception or ideation, always comes last; the subjective process in either of its two degrees comes first. When, popularly, we say that an image comes into our mind spontaneously, we mean that, being alive, something is always going on in our nervous system, and correspondingly in our minds. The so-called spontaneous image is a survival of the fittest image of the moment during conflicting energisings of all nervous arrangements which have been already organised in us. It is evidently the same when the conflict is aroused by a presented object. There is a difference of degree in the subjective process as there is a difference of degree in the objective process. The faint subjective process, physically the centrally beginning change, is the so-called spontaneous survival, and is followed by ideation; the vivid subjective process, physically the periphero-central charge, is that initiated by a presented object, and is followed by ideation passing into perception. There is a subjective stage in one of two degrees ending in the survival of the fittest images before the objective stage of reference of those images to the environment in one of two degrees.

We seem to perceive an object without a prior stage because the earliest part of this prior stage is unconscious or sub-conscious. But it is plain that we could not perceive—or, let us use a stronger word, recognise—an object, unless we had always organised in us an image which that object could rouse *in us*, or rather, images of all degrees of resemblance to the one which, surviving, is, for us, what we call seeing the object in the environment.

(To be continued.)

PAUPERISM AND DRINK, WITH SOME REMARKS ON THE MEDICINAL VALUE OF ALCOHOLIC BEVERAGES AND THE MORTALITY FROM ALCOHOL IN WORKHOUSES.

By THOMAS M. DOLAN, F.R.C.S.Ed., L.R.C.P.E., &c.,
Medical Officer Halifax Union Infirmaries.

I.

The temperance question, or rather the propriety of using alcoholic preparations in workhouses, has repeatedly come before the board of guardians to whom I am medical officer, giving rise to very interesting discussions as to the value of alcohol as a medicine.

My attention has necessarily been attracted to the subject, not in consequence of the reports of these meetings, but from its scientific side, I have considered the question, in the hope of arriving at some satisfactory conclusions to guide my practice.

Personally, I have a predilection for temperance, or total abstinence, having practically tested, by my own personal experience, the possibility of preserving health and doing a very large amount of physical and brain work without any alcoholic stimulation. So far then I established one great point, that alcohol is not essential to one individual's health. Can I push my own experience to the conclusion, that because I individually can do without alcohol, *ergo* every other individual can do without it?

After mature consideration I do not consider such a deduction tenable. I have questioned and examined a number of patients and friends who were anxious to abandon the use of alcohol in every form, but by the test of their practical experience and my own practical observation of the effects of total abstinence on their health, I have found, that total abstinence would not suit their individual constitutions.

This experience singularly accords with the axiom of one of the great fathers of medicine, Hippocrates, who says, "Wine is a thing wonderfully well suited to man, if, in health as well as in sickness, it is administered in moderation and judiciously, according to the individual constitution."

I have, however, arrived at the following primary conclusions:—

1. The majority of people can dispense entirely with the use of alcohol in any form, without injury to health.

2. A large number can not dispense with it, moderation or temperance being the better course.

3. Children and young growing people do not require it, except under special conditions.

Having satisfied myself so far, and established a certain number of general principles, some other questions required solution, questions upon which there is the greatest diversity of opinion. As—

Is alcohol a medicine? Should it be discontinued in my hospital practice?

If medical opinion is of any value we must look to men who are acknowledged leaders in the profession for its rational exposition. But here at once I am met by a difficulty.

What guidance can be derived from such contradictory teachings, for on the one hand I find Dr. Richardson with a number of able men, condemning alcohol *in toto*, whilst on the other hand there is an opposing camp, composed of men equally able, conscientious, and impartial, in favour of alcohol as a medicament. I have but to turn to the pages of the *Contemporary Review* for proof, for there may be found a series of inharmonious utterances, emanating from physicians and surgeons who have made a mark in the medical world.

A brief synopsis of the argument of each paper will clearly prove, that the searcher after Truth cannot derive much assistance from this source.

Sir J. Paget advocates the moderate habitual use of alcohol as certainly pleasant, and probably useful. Of moderate drinking, he thinks the balance of medical and of popular feeling favours it, and that neither statistics, nor physiological or pathological researches, have proven it injurious. He doubts the inherited evils which are propagated and handed down from drinking ancestors, and finds no proof of it in comparisons of different nations.

Dr. T. Lauder Brunton discusses how and when alcohol may be of value. He thinks that to a small class it may be a poison, and to a still smaller number it may cause mania. Another class is exhilarated, markedly so, and to such persons the risk is great. Most persons do not need alcohol, and are better without it; but late in life it is excellent, and acts often as food, and as a stimulant.

As a food, it is one which sometimes interferes with the oxydation of other foods in the body, while it is being itself decomposed, and as a food it is only adapted to febrile conditions. As a stimulant alcohol is often useful to tide over a severe crisis, but its best effect is in rousing the system at the close of an exhausting work.

Dr. Albert J. Bernays describes with great minuteness the causes and extenuating circumstances of intemperance. He thinks the water, the adulterations of beer, the bad atmosphere, and the variations in the strength of alcohol, are most common causes. Beer is considered the safest kind of alcohol, and wine the next best. Teetotalism, in his opinion, is no remedy for intemperance; we must secure it by other means.

Dr. Walter Moxon is also opposed to total abstinence. After a long argument to show why men drink, he defines it both a blessing and a curse, and thinks certain temperaments are more susceptible to alcohol than others.

Digitized by Google

Dr. S. Wilkes defines alcohol to be a narcotic, and not a stimulant. He shows how its use has become so general over the country; that its value is chiefly that of lessening pain and suffering, the same as opium, or other narcotics.

Sir William Gull is confident that in disease and debility it is useful, and also in over-work. But the constant use of alcohol is dangerous, and should be avoided. Short of drunkenness, alcohol is the most dangerous agent in the country.

Dr. C. Murchison doubts if alcohol has any value in health; but in some kinds of disease and debility it may be very beneficial. He makes a special point of arguing that it should not be used on an empty stomach.

Dr. James Risdon Bennett urges the temperate use of alcohol as both a food and a medicine. He is confident that physicians have investigated the facts very thoroughly and that a middle-aged man may safely use it in moderation, but children and young people must abstain. As a medicine it is invaluable, in his opinion.

Dr. C. B. Radcliffe believes that alcohol is both a sedative and stimulant, and as important as opium or quinine in medicine. He urges that it is a cheap food to be used by all classes in moderation. Drunkenness is the exception to the rule. Moderation must be learnt by each one for himself.

Dr. Joseph Kidd would have all men educated to restrain their animal passions, and thus indicate how far alcohol could be safely used. In large doses it is a poison; in small doses it may be a food. If it was studied on a scientific basis, and minute directions given as to its use, little danger would follow.

Mr. R. Brudenell Carter relates his own experience in favour of alcohol. He calls teetotalism a delusion, and believes the disasters from alcohol originate from impurities. The more pure, the less liable to be taken in excess. The palate will not lead the man astray if it is properly gratified.

Dr. A. B. Garrod urges that alcohol be taken largely diluted in water, and only at meals. That it is of great advantage, both medicinally and otherwise, if taken properly.

I might quote *ad libitum* from other sources, but it would only tend to heighten the difficulty, for a moderate-sized volume might be compiled, in reference to the action of alcohol on the body, filled with opinions the most opposite.

Continental writers of acknowledged eminence have thrown in their weight on the side of alcohol as a medicine; and I need only allude to Bouchardat, Pasteur, Gay-Lussac, Duprè, Beaumetz (France), Professor Polli (Milan), P. Semola (Naples), and P. Binz (Bonn), as exponents of the belief that wine is both beneficial and a powerful medicinal agent.

I may add one quotation from Dr. Prosper de Pietra Santa, director of the *Journal of Hygiene and Climatology*, (France), who thus sums up his opinions:—"When we see a vine meandering over a cottage wall, framing the windows in its green wreaths, perfuming the air with its flowers, distilling wine from its wild aromatic juice, for the man who works, for the old man who rests, we feel full of admiration for this graceful plant; indeed, no other plays so weighty a part for good or evil in the life of humanity. So powerful for evil as to become the executioner of reason and the corrupter of morals; so powerful for good as to shed joy upon the thorny path of life, to prolong the days of some precious existence. It forms an integral part of the history of humanity, and its fertilising influence runs through the scale, from the hymn to the orgy, from generous enthusiasm to prostration, from the songs which waken a nation to the *delirium tremens* which decimates a whole generation. Blessings and curses which inspired St. John Chrysostom with these poetical words—

'Wine is the work of God,
Drunkenness is the work of the Devil.'"

The individual who attaches weight to names, must be sorely perplexed by this array of conflicting testimony, for when he places in the balance, the name of Dr. Richardson, he can oppose to it another name of equal importance, and similarly with other leaders of the temperance movement. Nay, more, I consider it must be admitted that if names (*a*) are any criterion, there is a preponderating weight on the side of those who advocate the judicious use of alcohol as a medicine.

But names have not had much weight with me in forming my estimate of the value of alcohol; and though I have adopted and carried out for years, the principles laid down by Professor Miller, of Edinburgh, it was not his name which attracted my adhesion. His logical and consistent reasoning, his clear and lucid exposition of the general question, his calm and dispassionate advocacy, his striking and stern facts, joined to his lucid classification of the various actions of alcohol, carried conviction to my mind.

Though new theories, as those of Anstie and Duprè, supported by experiments, have been advanced in opposition to those of Lallemand and Perrin, whose views were supported by Miller, yet his general principles are unshaken; and since the alcohol question has been on the *tapis*, there have been very few new ideas announced, or fresh facts adduced, to supplement those contained in his work.

Successive writers have gone over the ground quartered by Miller, and have repeated him, though they have altered the form of expression, and clothed in other language, probably unconsciously, his ideas.

In "Alcohol, its Place and Power," we have a text-book in which alcohol is classified, both rationally and scientifically, and a proper place and power are assigned to it as a food, as a poison, as a luxury, and as a medicine. Published by the Scottish Temperance League in 1861, nearly 36,000 copies have been circulated, but yet it does not seem to have reached the hearts and minds of the profession, for if it had, I do not think we would have required the declaration of "270 of the leading physicians of Great Britain," nor would we have been treated to the symposium of the *Contemporary Review*, for we would have had a universal concensus of medical opinion, based upon rational principles.

Though, as I have said, later theories and experiments are opposed to Miller's view, that alcohol is not a food, yet he seems to have grasped its practical value as an indirect agent, not in building up tissues, but in preventing waste, and also to have foreshadowed modern views as to its paralysing and stimulating influences.

There is yet a diversity of opinion as to the true action of alcohol, though it would seem that the more favourite views are that, in large doses, it acts as a narcotic or de-depressant, whilst in small doses, and in the first stage of its action, it is a true stimulant, conducing to the activity of nerve force, and to the sustentation of the system under exhaustion or feebleness, as a food-medicine, views which are disputed by Dr. Richardson, and other able leaders on the total abstinence side.

Whatever theory may be true, I have practically tested its value, and I am compelled, by the force of experience, to include it in the list of my therapeutical agents; and more particularly in workhouse practice, do I believe it be an agent of indisputable power, when used judiciously, and on the lines laid down by Miller.

It cannot be denied that it is largely used without necessity, as a placebo, and as a reward for extra labour imposed upon the inmates of poorhouses, but this fact does not invalidate its proper use and power, or form an argument for its entire banishment from our poorhouse infirmaries.

The granting of beer to able-bodied paupers must be looked upon not as a necessity, but as an expedient, to extract, both an extra quantity of work, and a more efficient performance of it, from unwilling hands, and it therefore comes under the head of economic administration and

(*a*) See Dr. Norman Kerr, "The Medical History of the Temperance Movement."

management. One half-pint of beer will not intoxicate, neither is it required; but the question arises, will a certain amount of work be done as satisfactorily without it, or will its denial lead to the necessary engagement of a larger staff of officers to ensure the performance of work, which might be done by unpaid labourers, for the cost of a half-pint of beer? This is a subject for the guardians' own consideration, and might be tested in a simple and effectual manner, by closing the tap.

(To be continued.)

Clinical Records.

MERCER'S HOSPITAL, DUBLIN.

Under the care of Mr. E. STAMER O'GRADY.

AMONGST the patients whose cases came to a conclusion during the month of October, were the following:—

Vesical Calculus.—Lithotrity.—A white-haired man, æt. 68, was admitted in a miserable condition, from constant and severe suffering. He required to micturate every few minutes; passing urine alkaline, very offensive, and with large muco-purulent deposits. The sound at once struck the stone, and also indicated the bladder to be extensively columnar. Examination was intensely painful. Four "sittings" were practised, at intervals of three, three, and ten days. At each of the three first sittings large quantities of a soft mortar-like stone were removed by means of a succession of lithotrites; but little *débris* could be voided by the patient in any position, or evacuated by the Clover apparatus. The last sitting became necessary in consequence of a small fragment which had heretofore eluded detection. A concurrent constitutional treatment was carefully attended to, and the bladder regularly washed out with acidulated water. In consequence of the vesical difficulty it was necessary to retain the patient in hospital for nearly six weeks after the last crushing. During this period he was repeatedly sounded, but no further fragment could be detected. The urine became healthy in appearance and character, and the man, perfectly restored to health, looked considerably rejuvenated in appearance.

Female Hairpin removed from Male Urethra.—The patient, a well-developed man, æt. 28, a sailor, was admitted in a sorry plight, having, in addition to a severe clap, the foreign body impacted far down the passage; the points were located anteriorly, and deeply imbedded in the inferior wall four and a-half inches from the meatus. The man was reticent as to the *raison d'être* of his state, but it was ascertained that with the idea of curing himself of the gonorrhœa by scooping the discharge clean out, he had the day before admission extemporised a species of cuzette with the hairpin. This slipped his grip, and continued to pass deeper and deeper to the position which it now occupied. During the manipulations for its removal, the further progress of the pin towards the bladder was prevented by firm pressure on the perinæum, maintained chiefly behind the bend of the pin. The efforts made by the urethral forceps to bring the points of the intruder together proved abortive in consequence of their deep impaction in the corpus spongiosum, about a third of an inch of tissue being between them. Whilst the pin was held firmly in place a minute incision was made through the integument only, over one point, which was then forced through, and the lax skin slid over so as to bring the little cut over the second point, which was then similarly protruded through it. The pin was now easily pulled out till the little bridge of corpus spongiosum hitched in the bend, when, the pin being rotated so as to present this portion of it towards the meatus, it was pushed along and readily extracted. (*a*) No escaped urine nor extravasation occurred from the little cut, no mark of which in a couple of days could be found. The patient took his discharge by his own desire on the third day, only a little inflammatory induration marking the locality where the points of the pin had lacerated and pierced the urethra.

Stricture—Internal Urethrotomy.—The patient was an intemperate tailor, æt. 49, the subject of chronic stricture. A drinking bout had caused complete stoppage, which threatened for some time to necessitate puncture of the bladder. The man was apparently an unfavourable subject for operative interference, but assiduous trial for more than three weeks, during which he often had severe rigours, failing to dilate the stricture beyond the size of a one and a-half bougie, it was decided to cut it. Maisonneuve's instrument, with the blade running on the concavity, was used. So close and rigid was the stricture that considerable pressure had to be exerted to cause director to follow in the wake of the filiform bougie guide. A No 11 gum elastic catheter was passed immediately. There was scarcely any bleeding, no unpleasant sequelæ occurred, and the patient was discharged a week after the operation able to urinate with perfect ease, and a No 11 passing readily.

Circumcision (Three Cases).

A. Phymosis complicated with bad Bubo.—Patient æt. 32; trouble acquired and very close. After circumcision by Ricord's mode the parts healed kindly. Subsequent to this little operation a heretofore small and indolent bubo increased with amazing rapidity; was opened, and required much care in dressing to prevent the formation of burrowing sinuses.

B. Partial Phymosis complicated with Warts.—Patient æt. 17; trouble congenital. The ring of the prepuce was a regular circle of warts, a further large quantity of which could be felt beneath the foreskin. The operation was as in the preceding case, the warts being clipped and shaven off after opening up the parts. "Butter of antimony" was freely applied to all the cut surfaces. The case made an extremely rapid recovery, healing being nearly complete when the patient left the hospital five days after the circumcision.

C. A lad, also æt. 17. The details of this case are very similar to the preceding, except that there was also present a bad gonorrhœa. A week after the circumcision the patient was discharged to attend as an out-patient, with the parts in a healthily granulating condition.

Vesico-vaginal Fistula.—The patient, æt. 30, a remarkably large, fat woman, also suffered from badly ulcerated legs. The vagina was obliterated entirely from its commencement by dense cicatricial tissue, leaving only an opening which would admit the finger into the bladder. Some months earlier an operation to close this opening had only reduced it in size. On the present occasion it was considered desirable to attempt closure of the vulvæ. In the operation the ordinary quill and superficial sutures were used; the issue now, too, was only a partial success. Union of the apposed surfaces for the most part failed; but there was gained, the patient said, a knowledge of the coming flow, which often enabled her to save herself. The improvement seemed likely to increase as the parts healed in. The patient was obliged to leave the hospital whilst yet a large portion of the surfaces operated on remained unhealed.

Operation for Rupture of the Perinæum occurred in a small frail creature, who, when confined, three months previously, of a full-time live child, was not yet 15 years old. The labia were freely pared in the ordinary manner, and the round surfaces brought into and steadily retained in apposition by quill and superficial sutures. The case progressed very favourably, the girl being discharged eighteen days after the operation with a good firm, and quite normal-looking, perinæum.

Excision of Upper Jaw, on male, æt. 60, for a large

(*a*) It measured three and a-half inches in length.

Digitized by Google

antral growth on the right side, protruding the eye, and causing swelling beneath the cheek; there was not much encroachment in the naris. Five months previously some apparently ordinary mucous polypi were removed by the snare from the same nostril, and on the present occasion some seemingly similar innocent growths were there developed again to a moderate extent. It was only a month since the trouble in the upper jaw was observed, and since it was first noticed it had increased rapidly. The patient was a feeble man, with very weak heart, which intermitted badly. In accordance with his own wish, and in consideration of his extreme suffering, was determined to remove the jaw; this was done under chloroform, which acted admirably. An incision running along the lower border of the orbit, down the side of the nose and its alæ, and through the centre of the upper lip, enabled the cheek to be raised and thrown back. The parts were very vascular. Several bleeding vessels having been secured by catgut ligature, the muco-periosteal covering was stripped from the palatal aspect of the bones by an angular rasparatory, and the osseous attachments of the upper jaw were severed by powerful bone forceps. The whole mass was readily removed. The deeper portions of the bone proved to be extensively disintegrated by the disease. A separate growth, as big as a walnut, was dissected out from beneath the eye, and some suspicious-feeling material was scraped and gouged away from the under surface of the ethmoid by a Volkman's sharp spoon. Some bleeding points were cauterised. The preserved muco-periosteal covering of the palate was now attached by interrupted sutures to the mucous membrane of the cheek, and suitable plugs of lint (wrung tightly out of carbolised oil), to which were secured guiding cords, for their after extraction, having been placed *in situ*, so as to support the eye and the cheek, the soft parts were brought together by hare-lip pins and interrupted sutures of carbolised catgut, and further duly supported by adhesive strips and pads; all the guiding strings of the plugs were brought out in the front. Half-a-grain of morphia was given subcutaneously. The patient soon rallied, and became warm and comfortable; there was no sickness of stomach; during the day he passed water, and took fluid nourishment readily. A good night was subsequently obtained. The morning after the operation there was much fœtor. The plugs, which came away readily, were removed, and the cavity syringed out with a solution of Condy. The use of a mixture of quinine, iron, and digitalis, which had been given before the operation, was resumed. In the evening a quantity of blackened blood, that had been swallowed, was rejected. The progress of the patient seemed to continue to be most satisfactory; he took fluid nourishment and stimulants readily; the cardiac intermittencies lessened in frequency, and the line of the wound looked charmingly. On the evening of the third day there was some diarrhœa, which castor oil in hot milk promptly relieved. Next day the improvement was progressive (one needle was removed), and when seen at midnight all still promised well; but at 4 a.m. he died very suddenly, ninety hours after the operation. *An autopsy* was not permitted; it could only be ascertained that locally matters had continued so as to indicate a most thoroughly satisfactory result had the man lived.

Complicated Double Hare-lip—Scarlatina.—Male, æt. 9 months; there was considerable deformity, cleft palate, with the intermaxillary mass projecting at the tip of the nose. The density of the structure preventing the restoration of this in its entirety, the septum was nipped, and the osseous portion in front shelled out of its muco-periosteal envelope. A large vessel spouting on the face of the divided septum was staunched by the pointed actual cautery. The edges of the fissure were pared by the scissors. The parts came very nicely together, without deformity. The infant passed a good day and night. Next morning he seemed to be doing well, the face, however, being more swollen than usual; in the evening he looked badly, was cross and feverish; during the night the cutaneous manifestations of scarlatina developed, this trouble steadily progressing from bad to worse, proved fatal 120 hours after the operation. When, at the end of the fourth day, the needles were removed, the parts, notwithstanding the concurrent constitutional trouble, proved to be united in a most satisfactory manner; had the child lived, the result would have been all one could desire.

Only for the confession of the mother it would have remained unknown how the scarlatina was contracted. In consequence of a cold the infant got on the journey up to town, it had been in the hospital for 17 days prior to the operation—he was amongst the first to occupy a ward newly opened, fresh from the tradesmen's hands, after the annual scraping, distempering, and, on this occasion, painting. Moreover, no case of scarlatina had been in the hospital for many months. Careful inquiry eliminated the likelihood of any of the students having been the means of infecting the child. The mother had not been allowed out on pass, but subsequent to the child's death she stated that one of the tradesmen, who had been employed on the work at the hospital, had been in the habit of fondling the infant, and that, though he told her his own family were at the time laid up with the disease at home, yet she permitted him to continue his attentions to her child. (*a*)

Cancer of Angle of Mouth involving both Lips.—A healthy-looking man, æt. 48, was troubled as indicated at the right side, the disease extending as a caudate prolongation more than half-way across the red edge of the lower lip. The cheek having been transfixed, the scalpel cut above the cancer so as to remove the outer fourth of the upper lip, the knife then ran obliquely below the mass to a point corresponding to the commissure of the mouth (making a ≻) ; thence the incision was sloped upwards, so as to slice off the implicated red border of the lower lip, rather more than half its length. For a distance corresponding to the extent of the normal mouth, the mucous lining of the stump of the lower lip was whipped to the skin by the continuous catgut suture. The same manœuvre was repeated with the upper lip, and the remainder of the wound brought together with three hare-lip pins. The man made an admirable recovery, and was discharged from hospital in a fortnight with scarcely any deformity, and but little mark or trace of the extent of disease which had been removed. Careful strapping and dressing was maintained throughout the treatment. (*b*)

(*a*) There still remain in the hospital under treatment a female infant, æt. 6 months, the subject of single hair-lip *on the right side*, complicated with cleft palate and protruding bone. This was cut at the base, and forced back, when the soft parts were treated as in the above case. Both patients occupied adjacent beds, they were operated on the same day, and both sickened in a similar way, this one some hours later than the other, which was placed in an isolation ward as soon as the nature of its new trouble was known. For a considerable time this creature, too, lay in a most precarious state, chest trouble and diarrhœa supervening on the scarlatina. Eventually, however, amendment slowly began, and there now seems likelihood of a good recovery. The progress of the lip was at first all one could wish for; perfect union was obtained throughout. But the 11th day after the operation smart inflammatory action occurred around the alæ of the nose. The upper part of the cicatrix gave way subsequently, and through the ulcerated opening a tooth was extracted on the seventeenth day. A little plastic operation will hereafter be advisable to re-shift the side of the nose from its flattened position, and to close this perforation, but as the lower part of the lip has held firmly, with good union, and free from any depression or gap, an ultimately most successful result is anticipated.

(*b*) Another similar, but more aggravated, case remains at present under treatment, the patient here being a woman, æt. 70, the left angle of whose mouth, together with nearly half of the upper, and considerably more than half of the lower lip were involved. The trouble, too, in this case extended deeply and widespread, forming a huge prominent mass as big as a good-sized pear split and everted. The surface had bled, was painful, and stunk terribly. There was no glandular enlargement. It was scarcely a year since the trouble was first noticed. Only palliative results being contemplated, no attempt was made at the special formation of a new lip by the knife: yet treated as above described, the judicious use of carbolised catgut suture, and a few hare-lip pins, brought the parts together with a degree of deformity far less than could have been anticipated.

Severe Smash of Hand from Machinery.—A man, æt. 60, got his right hand jammed in the rollers of a paper mill, the damaged limb being held wedged for nearly an hour before it could be extricated. The amount of local damage was very considerable, the soft parts of all the fingers being split up; the palm and the back of the hand were both extensively lacerated; large flaps torn up; the tendons exposed and displaced. The second finger had the two upper articulations laid open, and the third finger was badly fractured; the soft parts of both in common with the other two fingers being greatly injured. Primarily it was attempted to save all the digits, but after a three weeks' trial the two specially named were disarticulated at the metacarpo-phalangeal joint, covering being obtained by lateral and irregular flaps where material for the purpose could best be procured. All along great care was necessary to keep the displaced soft parts in good position. A thorough though slow recovery was obtained, the patient being discharged with a soundly useful limb after a stay of forty-six days in the hospital.

Excision of Elbow.—A delicate girl, æt. 16, got permanent disease of the left elbow, as a sequel to general rheumatic trouble with bad gastric complications. She was long under treatment; finally abscesses formed, and sinuses led down to diseased bone. Some weeks in the country failed to accomplish either local or general improvement; and when the girl came into the hospital again for operation she was in a truly deplorable state. To her miseries had lately been added diarrhœa, which had rapidly emaciated her to an extreme degree. The joint was excised by a single long incision; the ulnar nerve was seen but gave no trouble. There was an unhealthy and fungous state of the mucous membranes generally, with much disease of the lining, requiring an oblique longitudinal slice to be taken off it. The radius and ulna were healthy. The wound was dabbed with a solution of chloride of zinc (40 grs. ad ℥j.), and put up in the straight position, ample provision for drainage being provided. Fair repair took place; the splint was left off on the twenty-fifth day; but still a good deal of attention was required to be bestowed on the dressing, and the practice of passive motion, so that it was more than two months after the excision before the girl could be sent to the Convalescent Home, a sinus still leading down to a bit of necrosed bone on the sawn side of the humerus. The long incision had been for some time covered over with a thick heavy scab, beneath which healing had been completed. The girl's health, though she was still weakly and puny, was greatly improved. There was nearly normal power of flexion and extension, pronation and supination being more limited.

ABSTRACTS OF THE INTRODUCTORY LECTURES AT THE DUBLIN SCHOOLS OF MEDICINE.

CATHOLIC UNIVERSITY.

The Inaugural Address was delivered by Dr. Nixon, Lecturer on Medicine in the University, who took for his text, "The Necessity of Mental Culture for Professional Students." After some preliminary remarks, Dr. Nixon observed:

I must remember that the occasion of the delivery of introductory addresses is intended to serve a double purpose. The speaker mainly devotes himself to that which specially concerns the interest of the student, and what may prove an incentive and encouragement to him in his career. But the publicity given to these discourses seems to imply that questions showing the relation of medicine to public interests and the State should be discussed—that the occasion should be availed of to point out the position and progress of medicine amongst the sciences, and to indicate its shortcomings and requirements. I do not wish to pronounce any opinion as to expediency upon all occasions of such discourses. I did not make the opportunity—unfortunately, it was found for me, and I purpose utilising it in directing your attention, in a purely suggestive way, to the claims which medicine has upon the sympathy of the community, its relation to other branches of knowledge, some of the methods of inquiry involved in its study, and the requirements of its students.

The social position which any profession attains depends upon the general culture of its members, upon its advancement as a science, and its improvement as an art. It is not very difficult to show the wide connection which medicine has with other sciences, standing, as it were, in the centre of the different pursuits of man. From mediæval time—when the physician was, besides being the healer of the sick, astrologer, alchymist, and often the minister of religious worship—down to our own time, we can trace the influence which it exercised upon society, because it embraced most of the known branches of knowledge subservient to the interests of mankind.

The speaker then dwelt upon the connection of medicine with collateral sciences as illustrated by the study of hygiene, which necessitated the study of the laws governing matter and force in relation to food, geology in relation to water, and meteorology in connection with the subject of ventilation. He then passed on to the investigation of the methods of inquiry employed in medicine as shown in the investigation of physiological and pathological laws. He continued as follows:

It would be altogether beyond the scope of a necessarily limited address to trace within even a brief period the advances made in the investigation of disease, and in that science upon which all knowledge of it rests. It will fully serve my purpose to indicate the method of investigation employed in the study of physiology and pathology, and to point out the influence which these branches exert upon each other.

The first great impetus to the study of physiology may be said to have been given by the carefully conducted experiments of Haller. From being a mere series of abstract reflections upon the nature of life, it has progressed to such a degree as to completely remodel our ideas of disease, and, to a considerable extent, our notions of practical medicine. This progress may be traced to the application of physical laws, and those governing the operations of chemistry, to explain the phenomena of life. Every change that occurs in the body implies chemical action, and, as in the ordinary laws of physics, the results are heat or mechanical work, or both. But the physics and chemistry of inorganic nature receive a large increment of abstruseness when applied to the investigation of the processes constituting life. Taken by itself, chemistry is known to be the least deductive of all the sciences. It is, *par excellence*, the science of experimentation. No train of reasoning would ever lead one to expect that hydrogen and oxygen, united in certain proportions, would form water, or that two fluids mixed together would form a solid. You cannot determine the nature or action of a compound from an analysis of its elements. The very fewness and partial character of the generalisations of chemistry serve only to show the difficulties that are experienced in its study. These difficulties, it can readily be observed, become intensified when chemical processes are commingled with a series of complicated physical phenomena, to which is added the unknown quantity of a vital force. The analysis of such phenomena gave rise to the development of what have been termed heteropathic laws, generalisations which have built up the entire superstructure of Modern Medicine. Thus it is shown that in certain cases a number of phenomena, instead of producing a result which is the sum of the separate causes, develops one which is completely heterogeneous. Yet, at the point of departure from the older and better known laws new ones are generated which become not alone capable of composition with one another, but give rise to laws which are themselves immutable and universal. The laws of Dalton and of Berthollet, and that of isomorphism, illustrate this development in chemistry; in physiology it is tersely laid down "that the Laws of Life will never be deducible from the mere laws of the ingredients, but the prodigiously complex Facts of Life may be all deducible from the comparatively simple laws of life." In framing these laws observation and experiment are the implements with which we work. The former, in its condition of perfection, implies the exercise of those mental qualities which are the distinguishing marks of superior intellectual gifts and high mental culture. For observation not alone means seeing the thing as a whole, but also the parts of which it consists, their kind, and the quantity of each; whilst the mental analysis which it involves intures that what is material will be carefully distinguished from what is unaccidental or important. It was observation

Digitized by Google

that led the minds of the greatest men to that concentration of thought which resulted in the most brilliant discoveries. Thus Newton discovered the law of gravitation from seeing an apple fall at his feet, young determined the laws of diffraction of light from observing the varying colours of a soap-bubble, and Galileo discovered a means of measuring time from watching the swinging motion of an oil lamp.

Having shown the value of observation and experiment in the study of physiological conditions, Dr. Nixon pointed out that in pathology, unfortunately, we have to trust to observation alone; we cannot ourselves, as in physiology, vary the circumstances. The experiments of disease are not those that we can take home with us—they are beyond our control, and we can only see them as they are presented. Hence the science of medicine must be built up more upon inferences than upon facts—upon probability rather than upon demonstration. But like as in those sciences which rest entirely upon observation, we have the advantage in medicine of reasoning in a two-fold way: we may from the effects deduce the cause, or, on the other hand, from the antecedents we may trace the consequents. Take, for example, a case of hemiplegia. You note all the concomitant circumstances—the existence of any lesion of sensibility, the state of the paralysed muscles, the condition of the face and tongue, the appearances in the retina, the evidences of renal disease, and the age and medical history of the patient. From the signs that exist you judge as to the nature and site of disease in the brain. Here you have reasoned from the effects to the cause. On the other hand, suppose you have been in attendance upon a case of valvular disease of the heart, and that the patient complained suddenly of acute pain in the left hypochondrium, accompanied by gastric disturbance, you at once infer that some fibrinous coagula have been detached from the diseased valves and lodged in the vessels of the spleen, producing there an hæmorrhagic infarction. In this case you have from a pre-known cause determined the effects. Each of these methods has its advantage under certain circumstances, but in both observation is liable to be vitiated by errors which are only to be avoided by special training. We must be careful to discriminate accurately between what we really observe and what we only *infer* from facts observed. It is largely owing to this confusion of inference with facts that medicine cannot be regarded as an exact science. Hence arises the necessity of specially training those faculties which are concerned in the investigation of the laws of evidence—of mental philosophy in general, and its key, logic. Apart from the great interest attached to the study of final causes, the habit of thought which is acquired by the reading of metaphysical works is in itself a high cultivation of the reasoning powers, whilst the perusal of the fine-drawn distinctions of such writers leads to the acquirement of a philosophic language for the expression of our ideas—an attainment of immeasurable value to observers of disease.

Dr. Nixon thought he had said sufficient to show that medicine is a learned profession, and that it is one of advancement. There is scarcely a branch of human knowledge to which it is not in some way bound. Its progress is not limited by the domain of physical science; it travels insensibly into the regions of mind, and is intimately associated with the greatest problems which can engross man's attention—religion and morals. It has been not inaptly termed the metropolis of human knowledge, of which we are the privileged denizens. But how are we to fit ourselves for the duties of citizenship? It was not his purpose, even if he considered himself equal to the theme, to point out the advantages of a liberal education apart from utilitarian considerations—to show why the acquirement of knowledge, or a philosophic habit of thought, should be its own end. What specially concerns us is the importance of varied mental acquirements and a sound and thorough education of those faculties which are constantly employed in the exercise of our profession. It is easy, doubtless, to find arguments for the usefulness of limitation of attention and study in the various divisions and subdivisions of intellectual labour. We recognise the advantages to ourselves and to the general public in the broad division of our profession, where practicable, into the fields of medicine and surgery; to ourselves in permitting us to concentrate our energy upon a limited part of a wide and great science; to the public in securing the services of better trained and more competent observers. We have further illustration of the benefits of limited attention in our profession in the practice of the different specialities, as in ophthalmic and aural disease, and in gynæcology. I do not say that specialism pushed to an extreme degree has not its disadvantages. It is apt to cramp and narrow the mind's range, to lead to an undue significance being attached to things which are trivial, whilst those of grave importance may be overlooked. But the question of the utility of exclusive devotion to professional pursuits, or of limitation of attention in any branch of knowledge, can only be said to arise when men are fitted intellectually to deal with the principles of any special calling. Great results are not to be expected from minds untrained. One cannot comprehend astronomy without a thorough knowledge of mathematics; to produce a musical composition of any value it is necessary to understand the principles of harmony. In both instances a certain amount of routine knowledge may be acquired and correctly applied, just as the mariner determines his latitude by observing the meridian altitude and declination of the sun.

It is quite true that men deficient in preliminary culture may attain some proficiency in learning the technical details of a special pursuit, but instead of following it with ease and a feeling of conscious power, they have always that sense of mental strain and diffidence which renders the work irksome and monotonous, whilst they can never hope to become original observers. It is in the one case like learning to swim with bladders; in the other it is as though you commenced dancing with loaded shoes.

Let the strongest man try to compete in a rowing match with the practised oarsman of a Cambridge or Oxford crew. He is utterly out of the struggle. The discipline of the gymnasia led to a race of men who boasted that one Grecian could overcome ten Persians. To conquer with the cæstus implied years of rigid training, in which not alone strength and agility were acquired, but a careful restraint was exercised upon the passions, lest they should weaken bodily vigour, or impair bodily beauty. It is precisely similar in mental contests. No matter what may be the natural endowments—how quick the apprehension, how varied the imagination, how tenacious the memory—if the mind be not fully instructed, and afterwards educated; first taught, then disciplined, so as to be rendered capable of methodising the knowledge which it has gained, it enters handicapped the race of life, and must inevitably sustain defeat. "Men are men," it has been well said, "before they are lawyers, or physicians, or merchants, or manufacturers; and if you make them capable or sensible men they will make themselves capable and sensible lawyers or physicians. What professional men should carry away with them from the university is not professional knowledge, but that which should direct the use of their professional knowledge, and bring the light of general culture to illuminate the technicalities of a special pursuit. Men may be competent lawyers without general education, but it depends on general education to make them philosophic lawyers, who demand and are capable of apprehending principles, instead of merely cramming their minds withdetails. And so of all other useful pursuits, mechanical included. Education makes a man a more intelligent shoemaker, if that be his occupation, but not by teaching him how to make shoes; it does so by the mental exercise it gives and the habits it impresses."

Such great importance is attached to this preliminary culture of the intellect in most of the German universities that no student is permitted to enter any of the professional schools until he has passed the "abiturienten," or leaving examination of the secondary schools. It is mainly owing to this system that Germany has produced such a lengthened roll of names distinguished in all the branches of medical science. And it is only by this preliminary culture, with the present advanced and advancing state of medicine, that we students—for we are all students, and I trust that we shall always continue so until called to another sphere—can hope to tread in the front rank of human progress.

CARMICHAEL COLLEGE.

THE new Carmichael School of Medicine and Surgery, Aungier Street, was formally opened by the President. Although the dissecting-rooms have been open for upwards of a month, the main parts of the building had not been fully completed, and even yet the board-room, as well as some of the ornamental work in the exterior of the building, is still in the hands of the builders.

Dr. GORDON recalled the circumstances under which the proprietary school was founded half a century since, and pointed to the distinguished success which had attended its teaching. The records of the school disclose a bead-roll of

Digitized by Google

illustrious names not surpassed by any similar institution in the United Kingdom; and from the ranks of its pupils and teachers every professional chair in Ireland was filled. He first named Dr. Robert Bentley Todd, who became eminent both as practising physician and still more teacher in London, and whose "Cyclopædia" and "Clinical Lectures" would remain as specimens of high intelligence and almost oracular penetration. Next there was Thomas Andrews, late Vice-President of the Queen's College, Belfast, whose investigations into ozone, heat, and the changes undergone by matter in passing from the liquid to the gaseous state were invaluable. Then they had Dr. Allen, who first projected a pupils' medical society, which it was most desirable should be now revived, and whose recent address on biological science at Sheffield was one of the most remarkable utterances on this most important subject. The names of Richard Carmichael and Robert Mayne should never be forgotten in connection with the school—the first as one of its greatest benefactors, and the second as one who conferred valuable advantages in the way of prizes—left a bright example in his life to all pupils, and might be regarded as the first who reduced physical diagnosis to a system. Immediately after the conclusion of the president's Inaugural Address, most of the audience made a tour of inspection round the new premises, and expressed their thorough satisfaction with the arrangements.

LEDWICH SCHOOL.

The Introductory Address was delivered by Mr. Alcock Nixon, F.R.C.S.I., Lecturer on Anatomy, and Surgeon to Mercer's Hospital. After a touching reference to the loss the school had sustained by the death of Dr. Ledwich, Mr. Nixon addressed the students particularly in reference to the studies which should engage their attention during the session, and went on to say—Since the date of the foundation of this institution, more than half a century ago, down to the present day, its aim and object has ever been to impart to its students (over 8,000 of whom have entered its portals) a sound, practical education, and that it has done so successfully is shown by the great confidence reposed in it—confidence which was never stronger that it is to-day, as proved by this year's entries, the largest in its history up to this date, and also by the fact that, in every quarter of the globe its *alumni* are to be found in the foremost ranks fighting the battle of life with marked success. As an example, I may mention the name of Surgeon-Major Boileau, who now occupies the important position of Assistant Professor of Pathology at the Army Medical School at Netley, and many others I could name did time permit. Medical students are, to my mind, one of the most maligned classes in the whole community. (Laughter.) We have always found them fair and reasonable if fairly and reasonably treated, while they stand staunchly and manfully by those whom they believe to be their friends. As a body they are generous, warm-hearted, and brave to a fault. Look at the record of our hospitals. A patient is perishing from hæmorrhage; the surgeon proposes transfusion, and on the instant, without a moment's hesitation, a volunteer steps forward from among his fellows, and freely offers his own blood to save the life of a dying pauper whom perhaps he had never seen before.

MEATH HOSPITAL.

The Inaugural Address of the Session 1879-80 at the Meath Hospital and County Dublin Infirmary was delivered on the morning of November 3, by Dr. John William Moore, Physician to the Hospital, in presence of a large gathering of the medical profession and visitors. In the opening part of his address, Dr. Moore alluded in appropriate terms to the lamented death of Mr. Robert Persse White, one of the surgeons to the hospital, and to the appointment of Mr. William Joseph Hepburn as Mr. White's successor, and exhorted the students to be diligent in their daily attendance in the wards of the hospital. Dr. Moore then proceeded to speak at length of one of the burning questions of the day in relation to the progress of medical science. He said that for some time past such expressions as "zymotic disease," "blood poisoning," "germ theory of disease," "antiseptic medicine and surgery," and the like, have been on everybody's lips. It occurred to him, therefore, that it would be neither uninteresting nor uninstructive were he to give a brief summary of the present state of our knowledge respecting what may, perhaps, be termed the "microcosm of disease." The topics, which were considered in some detail, were—(1) The microphytes of the blood and their relation to disease. (2) The nature of the virus in the contagium diseases. (3) The practical bearing of the subject. Under these headings, Dr. Moore sought to epitomise the present state of our knowledge respecting the organised or vital causes of disease. It was shown that there is good reason to believe that in the septic group of diseases, in relapsing fever, in malaria, in noma, and in some forms of diarrhœa, the presence of microphytes in the blood or other fluids of the body has an intimate causal relation to the phenomena of these several affections—the microphytes either exciting the disease themselves, or playing the part of a ferment which sets a-going the development of the specific poison or virus of the malady. It was also shown that in the contagium diseases the contagium is particulate, incapable of reproduction outside the body, and although not referable to the lower forms of fungi, nevertheless a "contagium vivum" growing and multiplying indefinitely when placed upon a congenial soil. What, then is the practical bearing of these researches? The expressions "preventable disease" and "preventive medicine" have of late years become "familiar as household words," and the lecturer could not help thinking that they are now likely to acquire a fuller and more precise meaning than they have ever possessed in times past. It is true there are some men even at the present day—conscientious, intelligent, and otherwise well-informed men—who object to the use of such a phrase as "preventable disease" on the ground that it is to say the least irreverent. They point to that close analogy which exists between the moral nature and the physical nature of man, both subject to laws which cannot be broken or violated with impunity. Any infringement of the divine moral law is followed by spiritual disease and death. No less certainly will the violation of the equally divine physical law, subject to which we live and move and have our being be followed by bodily disease and death. "The soul that sinneth it shall die!" Ah, yes, but do those who use this argument so solemnly, so fatally true, forget the glorious antithesis—God is "not willing that any should perish." And so we can believe that every earnest effort made to prevent disease and the misery it brings in its train has the divine sanction and approval. In striving to attain the prevention of disease, we may hope (1) so to modify the nature of the contagium as to render it inert or comparatively innocuous, as for example by vaccination in the case of smallpox; (2) to destroy it absolutely either (a) without the body or (b) within the body—namely, by disinfection and by antiseptic medicine or surgery; (3) so to counteract its effects upon the organism as to save the patient's life or even cause the symptoms quickly to disappear as for example by the administration of drugs, as quinine in ague. The lecturer concluded his notice of the "Microcosm of Disease," and of the lessons it teaches, quoting a short passage from a discourse delivered some years ago, in the theatre of the Royal Dublin Society, by a physician who was well known in the Meath Hospital, and indeed throughout the civilised world. The author to whom he alluded remarks:—Till the germ theory of contagion is established, till we know more of germ life, and of what preserves, what destroys it, and what replaces the latent by the manifest life, I believe that we must mainly trust to disinfection, cleanliness in the widest acceptation of the word. "It may yet happen—and God forbid that its possibility should be denied—that science will discover the essence of these affections, and with that the means of preventing and extinguishing them. When that is accomplished, preventive medicine will be employed directly, as it is now indirectly. Till that time comes, however, there is a great work for us to do. We have, on the one hand, to labour patiently, and in a severely inductive spirit, in the study of the natural history of epidemics, and their comparison in various portions of the world, avoiding conjecture, and honestly accumulating and analysing facts, which, thus treated, will in time crystallise into discovery." The writer of these weighty, almost prophetic, words was William Stokes—a name amongst the most illustrious in the heraldry of this hospital, in which, as physician, during well-nigh half a century, he acquired a wonderful experience of the natural history of disease. Far in advance of his contemporaries, his mind with eagle glance gazed into the future, foreseeing a

Digitized by Google

time when modern methods of research would pour a flood of light upon the causes and, as a consequence, upon the preventive treatment of disease. He lived only to reach the borders of that promised land, for even of earth's best and greatest the words are true—

"All that lives must die,
Passing through Nature to Eternity."

So he, too, passed away—to use the words in which he himself spoke of another—"after a long and splendid life of deserved and almost unexampled success, with "honour, love, obedience, troops of friends."

ST. VINCENT'S HOSPITAL.

THE Inaugural Address for the Winter Session was delivered by F. J. B. QUINLAN, M.D., F.C.P., Physician to the Hospital upon, "The High Death-rate of Dublin and its Causes." The lecturer commenced by a careful meteorological and topographical comparison between London, Edinburgh, and Dublin; and showed that there was nothing in the situation, climate, or other natural surroundings of these three cities to account for the fact of the alarmingly high death-rate of Dublin as compared with that of London or Edinburgh, which he described as remarkably low. Dr. Quinlan then entered into an elaborate detail of the reasons of the high mortality of the Irish metropolis, ascribing it to the very bad state of the tenement houses inhabited by the artisan classes; the general want of proper and safely constructed house drainage (even among the rich); the public sewers; the almost total absence of proper periodical removal of house refuse; and to the filthy condition of the streets. Speaking on this latter subject, he quoted the description of the Rev. Professor Haughton as to the geological disadvantages of Dublin; and expressed his own belief that the streets could not be kept clean unless they were altogether paved. After dwelling at some length upon the remedies for the present sanitary state of Dublin, Dr. Quinlan concluded his address, which was listened to with marked attention, and frequently applauded, with an eloquent allusion to Surgeon-Major Reynolds, V.C., who was present. The Hero of Rorke's Drift, on leaving, received a perfect ovation from the students.

Transactions of Societies.

HARVEIAN SOCIETY OF LONDON.

THURSDAY, NOV. 6, 1879.

The President, H. C. STEWART, Esq., in the Chair.

Dr. HUGHLINGS-JACKSON on

INTRA-CRANIAL SYPHILIS.

This was a case of a man of 38, where the following four symptoms were found:—1. Headache. 2. Paralysis of the third nerve on the right side. 3. Paralysis of the fifth and sixth nerves on the right side. 4. Paralysis of the fifth nerve on the left side. Six years before this he had a chancre, the scars of which still remained. The array of symptoms suggested syphilis. No one symptom is pathognomonic of syphilis, but groups of symptoms are. Severe headache is one of the worst nervous symptoms, and is a most important indication for treatment. Convulsions are the evidence that a gumma or gummata have formed. Where both syphilis and epilepsy co-exist, each must be treated; and thus iodides and bromides must be given together. Paralysis of the third nerve is suggestive of syphilis, though it is found with loco-motor ataxy, or aneurism of the posterior communicating artery of the circle of Willis. Paralysis of cranial nerves due to syphilis is rarely double. In consequence of the implication of the sixth nerve the man reeled slightly when the left eye was closed. As to the treatment, when syphilis implicates the cranial nerves, iodide and bromide of potassium are indicated. Mercury is called for when the new material has become consolidated into bastard connective tissue. The affected muscles will then plump out again. Hemiplegia came on after the local paralyses. Multiple lesions always indicate syphilis. Softening of the brain follows when an artery becomes perfectly blocked up by a gummatous growth, in consequence of its supply of nutrient blood being shut off. The actual softening is, of course, not amenable to treatment, but an earlier stage may be. Under large doses of iodide of potassium the patient got quite well. Plugs of recent origin may be absorbed. One night the patient was delirious; but this had no significance, as delirium is a general symptom of cerebral disturbance not confined to organic changes.

The PRESIDENT thanked Dr. Jackson in the name of the Society for his able paper.

Mr. POWER said that in eye disease of syphilitic origin he had not observed hemiplegia. He inquired how far gout or rheumatism might predispose to syphilitic disease.

Mr. ALDERSON related a case.

Dr. BUZZARD spoke of the diagnostic significance of groups of symptoms. Of old in severe headache it was customary to apply leeches and administer mercury—a plan which often gave good results.

Dr. SYMES THOMPSON spoke of cases resembling cranial syphilis.

Mr. JONATHAN HUTCHINSON spoke of the necessity for prompt and early treatment, even when the diagnosis was not absolutely clear; and related a case in point. Pain was not constantly present in intra-cranial syphilis; while it was often intense in non-syphilitic disease—as tumour, for instance. He had seen inherited gout in girls give rise to very severe headache, with disturbance of the muscles of the eyeballs. In loco-motor ataxy the eye disturbance generally gets well early.

Dr. JACKSON replied, repeating the statement of the necessity for the combined treatment of epilepsy and syphilis when co-existent. The headache of glioma, abscess, and cyst were indistinguishable. In his experience disease of the cerebral arteries did not give rise to pain. Of course it was most desirable to find definite and unmistakeable evidence of syphilis; but this could not always be found.

The meeting then adjourned.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 12, 1879.

THE OPENING OF THE SCOTCH MEDICAL SCHOOLS.—II.

IN peculiar contrast to Dr. Tuke's address, we have that of Professor Balfour at the University of Glasgow. This school continues to distinguish itself by its uneasiness on the subject of medical reform, and, inferentially, its dread of competition with members of the profession outside its hallowed precincts. Excusing himself in not possessing the age and experience which makes counsel impressive, Dr. Balfour chose to spin the web of his discourse in a region of science with which he was more familiar, and we honestly regret that we cannot compliment him generally on his skill as a weaver. He demonstrated the identity of the phenomena of vegetable and animal life, and, as if conscious of Dr. Tuke's simultaneous onslaught on his farm, he maintained that it seemed to him of some importance to bring out prominently at the present time the connection between the natural history sciences, and to point out their true relation to one another, in view of the widespread tendency in many quarters to underrate their value in medical education—an argument equally relevant to the study of the steam-

Digitized by Google

engine and aeronautics by that unfortunate "pillar of science," to apply Dr. Tuke's happy phrase, the medical student!

There was, Dr. Balfour alleged, at present an agitation for medical reform, heralded by the plausible cry of protection for the public. No one would deny that there was room for reform in certain directions, but it was open to grave question whether the sweeping changes in the character of the tests for medical licence, and the modifications of the course of study ["class-bias"] which had been urged, would produce the desired effect. It was "hard to conceive how the lowering of the standard of education to a minimum would tend to the better protection of the public, or how the exclusion from the curriculum of study of those sciences which even the reformers designated the fundamental medical sciences would produce practitioners more fitted for the work of their profession." This is an argument which naturally becomes the newest-fledged professor; he would sink the raft that carries him to land, that he and a few treacherous friends may more fully enjoy the abundance of the soil. It was Professor McKendrick's argument, and now the mantle is passed on to the last-elected professor. We flattered ourselves to have conceived that it was already made sufficiently manifest in these columns that it was "an argument" unworthy "the literary and scientific culture" of a famous university. Once for all, then, be it understood by Dr. Balfour and his academic *confrères* that *medical reformers have no wish to lower the standard of education to a minimum*, nor to exclude any subject of study *which would contribute to a more rational comprehension* of the art of healing—a comprehension at the present time, it would appear, of an appallingly perverted nature; they desire that the requirements shall be *as high*, if not *higher*, than those of the University of Glasgow, or any other Scotch University, while they contend that the liberty to teach such requirements should not be monopolised by any section of the profession to the detriment of the science at the expense of the student and the tarnished honour of any member of the healing art. Dr. Balfour concluded by a feeble rally in favour of his beloved "natural sciences" in medical education. Many of his statements are singularly inconclusive, and must fail in imparting the conviction that extraneous demands, both uncalled for and pernicious, are not made on the medical student of the present day, in the brief space of four years' study.

The Glasgow Royal Infirmary School of Medicine was opened by an address from Mr. H. E. Clarke. Having recently acquired the proverbial "cow," or by more strict analogy probably, "the calf," Mr. Clarke naturally felt it incumbent upon him to fence his possession. He had no doubt, he said, that some changes would be forced upon them, in spite of their wishes, and in order that the change might not be too radical ["class-bias"], it would be well to endeavour to effect some compromise, in order that harmony might once more reign in their midst. Dr. McKendrick would abolish the corporations entirely; Mr. Clarke would plead for a compromise that might save something from the wreck; and like most other newly-created radical teachers in Glasgow, he does not feign to conceal his intolerance of radical brethren still outside the *cordon*. His position is clear. He wishes, in the crash, to share the carrion with the Universities, and by way of a sop to Cerberus, the Crown is to be permitted to look on, and see that no throats are being torn while the carousal is proceeding. It could not be denied, he said, that a multiplicity of diplomas and licensing bodies caused much practical inconvenience to the public and the profession. Then the question is almost entirely conceded; but he contended (contention is but a mean accomplishment), that there was no evidence of the inefficiency of the present examining boards, and no proof that students selected the examinations of certain corporations because they were notoriously easy. He believed that an examination under the supervision of the State would be the most likely to give satisfaction, and so forth. It were wearisome and unprofitable to follow Mr. Clarke further.

We have deferred to the last our cursory review of the opening address at Anderson's College, for to the venerable Emeritus Professor of Physiology at the University of Glasgow must be accorded the palm of the "introductories." Dr. Buchanan's address was pre-eminently academic in tone, incisive in speech, and faultless in argument and common sense, with a judicious occasional dash of piquant humour. It must be a source of unfeigned gratification to his friends, that advancing years have not impaired an intellect peculiarly keen, and that his strength was such as to have enabled him to acquit himself so worthily of the task imposed upon him, remaining, more conspicuously so by contrast with the many medical babblers in our midst, still "the old man eloquent." *Habet senectus, honorata præsertim, tantum auctoritatem, ut ea pluris sit, quam omnes adolescentiæ voluptates.*" In the good old-fashioned way, Dr. Buchanan chose as his subject, "The present age considered as the age of biology; the advantages to the members of the medical profession resulting therefrom, and the correlative duties imposed upon them thereby." At the outset, Dr. Buchanan referred to the eminent men who had, in times gone by, been connected with the institution. He asked himself if medicine was ever to have its day of popularity? Were the professors of the medical art always to be regarded as quacks, charlatans, and knaves, and otherwise depraved? Such, from time immemorial, had been the position of the medical profession, and the estimate formed of it by the general public. Signs of a brighter day were appearing, stimulated by the age of biology first inaugurated by Cuvier. Referring to popular movements, he stated that they were attended with more or less risk, when the objects were indefinite, or not fully understood. He gave two illustrations of this, derived from the present time. The first was, the milk movement, originating with the "discovery" of Dr. Russell, and his sanitary enthusiasts. How in this age of biology was Dr. Russell's new doctrine received in Glasgow, where, in every drawing and dining-room questions of sanitary science, were familiar topics of discussion? Emotions were strongest in the female mind, and what mother could, without apprehension, and even terror, see her children drink, every morning, as much milk as might bring them to the grave. The mothers argued, entreated, upbraided, and implored, till at length their distracted husbands rushed forth in a state of desperation, and marched in a phalanx to the chief magistrate, and demonstrated to him the absolute, urgent, and imperative

Digitized by Google

necessity of convening a public meeting to consider the milk supply. In this way was inaugurated the great movement which has since extended to every corner of the three kingdoms, and seemed for the present to be strongest of all in London. He wished he could speak in the same laudatory terms of their coadjutors. But it seemed that they had overstepped their province in delivering an authoritative opinion on a subject of which they know so little as the causation of fevers. Neither could he approve of their milk companies, for he could see no good, but only harm, that would arise from interfering with an important branch of industry, and diverting it into another channel, in which it could not possibly continue; while, in the meantime, they were injuring, and perhaps ruining, many poor but honest people, who earned their livelihood by the sale of milk. Were we to suppose that the endemic fevers of our own country proceed from causes quite different from those that cause the endemic fevers of other countries; or, on the other hand, were we to suppose that in all those countries the drinking of milk is the common cause of, or at least one of the means of, propagating endemic fevers; that it produces the fever of Cyprus, of which we hear so much; the malarious fevers of Rome and Florence; the yellow fever which was now decimating Memphis and New Orleans; and the bubonic plague of the banks of the Nile? Dr. Buchanan then proceeded to speak of the alcohol controversy, maintaining that alcohol was a food in the sense that fats were; and while acknowledging that alcohol was, in excess, a full and overflowing source of disease, immorality, and crime, he regarded it, judiciously employed, as a good gift of God to man, which human perversity alone has converted into an instrument of evil.

As for the total abstinence movement, the age of biology having arrived, the mist of error and prejudice in which both parties were now involved would be at length dispelled, and good men would act in concert in framing a code of wise laws for the repression of intemperance.

May the worthy lecturer long live, and with the authority of his intellect and years, continue to frown down all pseudo-scientific pottering suspiciously suggestive of vulgar notoriety or personal vain-glory, which cannot fail to bring its quota of contempt on a confessedly difficult and abstruse science.

PAROCHIAL SANITATION.

THERE lie before us three separate reports supplied by Government sanitary inspectors to the Central Local Government Board, dealing with the hygienic defects of three different places. The story told in them is, however, with slight variations of detail, precisely the same in all. Deficient house ventilation, amounting in places to no ventilation at all; inadequate water-supply, occasionally absolute absence of the fluid from the vicinity of the habitations; imperfect removal of refuse, even to the extent of a persistent accumulation of human excreta and domestic rubbish; and, consequently and naturally, without exception, a high death-rate and epidemic outbreaks. The zymotic diseases find in such localities their natural home; and it in no way surprises us to learn that eruptions of scarlet and other fevers recur with annual regularity in the unhappy districts yet visited.

"In the Rochdale Road (we quote from the report dealing with the Urban Sanitary District of Crompton in Lancashire) the privy accommodation is most scanty, *one group of 23 houses largely populated having only three privies*" ! ! The inevitable sequence of this must be, the frequent abuse of the home facilities, and the accumulation in the homes, and about them, of fever-breeding masses of ordure. Inevitably, therefore, "at East Crompton typhoid fell heavily. At Wood End, small-pox, typhoid, and scarlet fever occurred;" and following the suggestion his experiences compelled, the inspector rightly urges that "excrementitial pollution of the soil and want of ventilation, if not the actual cause, kept up this disease and rendered it of a more fatal type." "This year," also, "the same localities have been again visited, and several deaths from typhoid and from scarlatina have occurred at Milnrow Road and Rochdale Road."

One statement in the same report strikes us with peculiar significance—viz., "The bye-laws relating to common lodging houses have never been put in force, although at the time of my visit there were many Irish mowers in the town, and on this and other like occasions there is need for specially careful inspection of the lodging houses." We can infer from this, and from the generally lax enforcement of legal restrictions by the local authorities here and elsewhere, that very much of the disgraceful state of affairs is due to the incompetence and ignorance of the parish administrative body. Nor can any hope of improvement in this respect be entertained until one of two things takes place; until, that is, the principle and practice of sanitary reform become familiar to the local authorities and constantly called to their assistance in parochial legislation, or a duly qualified and duly accredited Government officer is deputed to superintend and ensure by his presence the adoption of measures necessary to the preservation of the public health of the district over which he has control; and, further, to ensure that these measures are constantly observed.

The first condition we despair of witnessing until the limits of the country become conterminous with the "Salutland" of Dr. Richardson's imagination. The ordinary parish guardian's contempt for the "fadding" provisions, as he terms them, of Government inspectors, is too genuine and too firmly rooted to permit of his receiving the first germs of a newer wisdom and a wiser knowledge. He is too much in the habit of regarding the individual and collective intelligence of the "board" as perfectly able to regulate *all* the affairs of the district, and is intolerant of any interference from without.

Notes on Current Topics.

Special Entries at the London Hospital.

OUR attention has been called to the real meaning of the large number of entries in "special subjects" at the London Hospital, a number exceeding fifty. The majority of these, it is urged, are American and foreign graduates, who enter at the hospital for a single clinical course, and who then by virtue of an imaginary right of free access to each and every clinique, crowd the demonstrations of the physicians and surgeons. The consequence of this

Digitized by Google

system of wholesale admission of outsiders is, that the legitimate perpetual student of the hospital is more or less ousted from his place beside his teacher, and has to give way to strangers, who are often too by no means punctilious in their attempts to obtain and retain the best positions for seeing and hearing, to the exclusion of the pupil who claims the London for his *alma mater*. Largely increased as the number of full entries has been of late, we cannot but concur in the opinion expressed by many men who suffer from this irruption of *specials*, that they have a real grievance in the encouragement afforded to the birds of passage. It is certainly fair that those who elect to pursue their whole curriculum at the London Hospital should receive advantages of an educational kind superior to the advantages afforded to such men as merely seek a temporary instruction there; and, either special facilities should be given them for securing such advantages, or a limit should be placed on the pressure from outsiders, commensurate with the necessities incident to ward-teaching. From its nature, a clinic can be of material use to as many only as can be accommodated within sight and hearing of the patient, and the lecturer: but this is certainly not possible to all the hundred or more men who are seen to crowd round the members of the staff while making their tour of the wards at certain hospitals. In the interests of the full student some consideration should be given to this question, and some necessary restrictions of an efficient nature imposed, to prevent the injurious monopoly of clinical experience enjoyed, we are assured, by those who do not possess equal rights with the "perpetual."

A New Exploring Machine.

Mr. Thomas Stevenson describes in *Nature* an invention which enables an accurate examination of dark cavities to be made by means of a beam of light (electric or other), which is directed into any situation by successive refractions through glass prisms. The value of the instrument is likely to be well seen in the surgical exploration of dark cavities, which from the difficulty of directly illuminating them, can only be submitted to a hazardous operation. There is no physical reason why the ingenious contrivance of Mr. Stevenson should not enable every such operation to be brought within the region of possibility and safety.

The London Hospital.

The Princess Louise (Marchioness of Lorne) paid a private visit to the London Hospital on Thursday afternoon, and was escorted round portions of the building by the chief members of the staff and governing body. During her stay the Princess spent some time in the children's wards and evinced much interest in the little patients' ailments. This is one of several royal visits to the East-end hospital within the last two or three years, and the effect of them on the institution and the public that supports it is a beneficial one. We could wish to see a still stronger interest on its behalf excited, for as well as being the largest of the metropolitan charities, it is the sole general resource of the great mass of the population in the East-end.

Elections at Trinity College, Dublin.

Dr. Alexander Macalister has been elected by the Board of Trinity College, Dublin, to the chair of Anatomy and Chirurgery in the University of Dublin, which has been left open by the recent retirement of Dr. B. McDowel from the active duties of the Professoriate. Prof. Macalister is well known as the author of "An Introduction to Animal Morphology," Vertebrate and Invertebrate, and other works. He resigns, under the new arrangement, the professorship of zoology, which he held together with the chair of comparative anatomy and the direction of the zoological museum. The latter post also falls vacant now, but Dr. Macalister will continue his lectures on comparative anatomy. The election of a director of the museum rests with the College Board, and hitherto the professor of zoology has always held it. The combined emoluments of the two offices amount to from £300 to £400 per annum. The new professor of zoology will be appointed early in the present month.

The Homes of Medical Men.

The Annual Congress of Sanitary Reformers, held at Croydon last week, is provocative of a good many social questions. Amongst them may be asked—Are the homes of medical men built or constructed on model sanitary principles? or even are they altered to show how necessary it is to have healthy homes, with through and thorough ventilation? Are medical men acquainted with the actual position of the drains in their homes? or do they possess a ground-plan of their drainage? We are the leaders of sanitary science, and we tell the public you must do so-and-so; but our patients observe that their medical attendants live in houses far from being model ones, and they smile, and say *sotto voce*, "What is good for Dr. A. must be good for me. And as he is content to live in a room without a single ventilator in it, why, I may do the same." We have noticed this subject, as we have heard it remarked and discussed by sanitary reformers outside the profession, and the conclusion they have drawn is, that unless medical men set a practical example, the public will not follow their advice, and sanitary reform will consequently be imperilled. In connection with medical men's homes we may notice another point, viz., the papering of the rooms. Are the papers free from arsenic? Do medical men take precaution to ensure that their children's bedrooms are papered with a tissue free from this poison? We fear not. Our few words may have some effect in directing attention to a most important subject.

Irish Registrars' Sanitary Reports.

We referred last week to the responsibility which the efficient discharge of his duty entails upon an Irish medical officer of health, to the experience of Dr. Barry, of Limerick, who was threatened by his sanitary authority if he persisted in recommending a disinfecting chamber; and of Dr. Wallace, of Parsonstown, who was called upon for an explanation because he had stated in his quarterly report that the discharge of his sanitary duty had "got him into hot water" with his guardians. Being anxious to see Dr. Wallace's report and the context of his statement, we referred to the published returns of the

Digitized by Google

Registrar-General, and did not find there any report whatever from Dr. Wallace. We therefore assume that Dr. Wallace's report must have been confidentially communicated from the Registration Office to the Local Government Board, and injudiciously sent on by the latter department to the Board of Guardians. We believe that it has always been the custom for the Registration Department to collate for publication such portions of these reports as seemed suitable, and to send forward to the Local Goverment Board other portions, which—though important—were not fitted for the Quarterly Return. Such system is necessary for the efficiency of the sanitary system; and without it we believe that the Local Government Board would be even more helplessly at sea as to the public health of Ireland than it now is; for we conceive that these confidential reports are made the subject of special inquiries by the local inspectors, and thus the facts become known at the Custom House. It would be, therefore, most disastrous if medical officers of health should acquire the impression that they were liable to answer to their boards of Guardians for the honest expression of their opinion and their experience; and we believe we can say that this is not so, and that the communication of Dr. Wallace's report to his local masters was a chance error. At all events, we are sure that the present Registrar-General will not permit his reports to be used in any way which would be disadvantageous to their writers.

There is one conclusion derivable from this episode which deserves consideration. We know already—and our readers, by perusal of the abstracts published in our "Supplement" to-day, may see for themselves—that the working, or, we should say, the pretence of working, of the Public Health Act in Ireland is denounced by the local medical officers in all moods and tenses. But it seems that there is much contained in these reports which it is not thought expedient to publish; and we may guess what the elided portions of these reports say of Irish sanitation. We suspect that the chorus of contempt and dissatisfaction is loud, long, and vehement; and that the Irish Local Government Board is, therefore, more thoroughly aware than we supposed that the sanitary system of the country is a pernicious sham. The more it knows of the real character of that system, the more reprehensible are they in lending themselves to its continuance and obstructing its amelioration.

The Public Health Organisation of Dublin.

We are truly gratified to find ourselves outside the fault-finding vein which we have been obliged to assume *en permanence* in reference to the Dublin Sanitary Organisation. Since Dr. Cameron, the newly-elected medical superintendent officer of health, was installed in office the prospects of something being done to save the lives of the city poor and relieve the senses of the citizens of the nastiness of Dublin seem to be rapidly brightening. The white-washing process has been transferred from the Public Health Committee's reports to the interiors of the tenement houses, and an increase of earnestness in sanitation is delightfully manifest.

Amongst the movements which have followed upon Dr. Cameron's ingress to office is the establishment of a "Metropolitan Medical Officers' Association," an organisation of the whole of the medical officers of health for the city and the metropolitan unions, to compare notes and concoct means of sanitary reform. The first meetings of this Association have been held at the Irish College of Surgeons, and we wish it even a greater success than its promoters can hope for.

Paregoric without Opium.

A CHEMIST, in Derbyshire, was last week charged with selling as paregoric a preparation which was entirely destitute of opium.

The inspector went to defendant's shop for three ounces of paregoric. Defendant served him, and he paid 8d. for the three ounces. The public analyst had reported that the preparation was entirely wanting in opium, of which there should be two grains to the ounce.

Defendant said he purchased it of Greaves and Sons, of Chesterfield, and that they informed him he was right in selling it as a mixture free from opium. To this the analyst gave the following reply:—"'Paregoric Elixir' always was, and always is, understood to contain opium. No one objects to shopkeepers selling a common domestic medicine (free from poison), if they will do it under such a name as not to cause mistakes. Dangerous and even fatal results are continually happening owing to the preparation, destitute of opium, being sold under the name of 'Paregoric.' Its failure to produce the intended effects lead to an increase in the dose, and then when the genuine article is obtained, as it will be if a druggist is asked for it, poisonous effects are produced." A nominal fine of 1s. was inflicted, with costs 11s. 6d.

The Mortality in Dublin.

THE deaths registered during the week ending 1st November represent an annual mortality of 30·6. The average annual death-rate of eight large town districts of Ireland (including Dublin), calculated on last week, was 28·4. In twenty large English towns (inclusive of London, in which the rate was 21·6) the death-rate averaged 21·9; in Glasgow, 14·3; in Edinburgh 16·1; in the Dublin District, 200; 86 deaths, or 46 per cent. of the total, were of children under 5 years of age, 37 being of infants under one year old. There were 41 deaths from zymotic diseases registered, being 8 less than the number in the previous week, but 8 over the average for the 44th week of the last ten years; they comprise 6 each from small-pox and scarlatina, 8 from measles, 4 from diphtheria, 3 from croup, 2 from whooping-cough, 3 from fever (2 typhus and 1 typhoid fever), 3 from diarrhœa, &c. The registered deaths from small-pox are one less than in the preceding week. Thirty new cases of this disease were admitted into the Dublin hospitals last week, being 10 over the number admitted in the week ending 25th October; 88 remained under treatment on Saturday last, being 10 more than the number in hospital at the close of the previous week. The new cases of scarlatina admitted into the hospitals are 7 in excess of the number in the previous week; 9 cases of pneumonia were admitted, against 5 in the preceding week.

Workmen's Donations to Hospitals.

We are glad to notice a growing tendency on the part of working-men to devote a small portion of their earnings in a systematic manner to hospitals. The Hospital Saturday Fund in London this year exhibits a considerable increase in this direction, whilst in Birmingham the change is still more marked. It has been found that in every case which has come under notice where weekly contributions have been made, the amount raised on behalf of the Hospital Saturday Fund far exceeds the sum similarly raised in previous years. The following notable instances may be given:—One establishment, in 1875, contributed only £3 15s., and it was then decided to adopt the penny weekly system. In the following year the amount was increased to £17; in 1877 it reached £55 4s. 2d.; in 1878 it rose to £91 14s.; and this year the sum of £109 2s. 4d. was paid in. Another firm, whose contributions had previously never exceeded £17, adopted the penny weekly system, and at the next collection they had upwards of £50 available for distribution. Another firm have, by the adoption of this system, increased their subscriptions from £2 2s. in 1875 to £15 at the last collection. The system has been adopted in very many of the manufactories of the town, and many more establishments have notified their intention to adopt this system of contributing at the next collection. In many instances, where the work-people wish it, the employers allow the pay-clerk to deduct the amount from the wages of each contributor weekly, and this plan is found materially to facilitate the collection of the contributions.

The Dangers of Chloral.

The dangerous nature of chloral has received a melancholy illustration at Carlisle through the death of Dr. Wm. Hay, a well-known practitioner of that city. At the inquest on Friday, the Coroner, Dr. Elliot, recommended that public attention should be drawn to the fact that chloral does not, like opium, lose its power by repetition; but it may, if repeatedly taken, exert a sudden cumulative action resulting fatally. He insisted, further, that chloral paralyses the heart's action, and may produce sudden death before any remedy can be applied. The deceased was shown by medical evidence to have had a disproportionately small heart, and therefore, possibly, more amenable to the fatal effects of chloral poisoning. More precaution seem to be called for with respect to chloral, especially since the preparation which proved fatal to Dr. Hay was shown to have been very considerably stronger than that in ordinary use, one minim being equal to a half-grain of the drug. It may be remarked that the Carlisle City Coroner (Dr. Elliot) was first instrumental in securing the inclusion of chloral among poisonous drugs.

Of diseases of the zymotic class Portsmouth, Plymouth, Sheffield, Newcastle-upon-Tyne, and Dublin showed the highest death-rate. Scarlet fever was fatal in Bradford, Sunderland, Liverpool, Newcastle-upon-Tyne, and Dublin. Three fatal cases of diphtheria were recorded in Birmingham. Small-pox caused one more death in London, 6 in Dublin, but not one in any of the other large towns.

A Medical Fracas.

It is with profound regret we learn that an assault has been committed by one medical man upon another in the open street. A good deal of gossip is rife in London medical circles relative thereto, and we fear that something graver than any mere breach of professional etiquette must have caused this assault. We hear, however, on good authority that an apology has been tendered and accepted, and the matter will probably end thus. It is a pity that some understanding had not been arrived at before the gentleman applied his walking-stick to the person of a professional brother. Personal chastisement is rarely resorted to nowadays, in this country at least; and we deeply regret that any medical man should adopt this method of venting his grievances upon another.

Dr. Rosa Welt, a young lady of Vienna, has been appointed assistant to the chair of Ophthalmology in Bern.

Richet says that, in general paralysis of the insane, the anatomical lesion is an alteration of the deep cortical layer of the gray cerebral convolutions.

Surgeon-Major Reynolds, V.C., has been taken on the strength of the Dublin District from the 6th inst., and ordered to proceed to the Curragh for duty until further orders.

Prof. Wright, who recently died at his home in Cincinnati, will long be remembered as a medical teacher, lecturer, writer and practitioner; the cause of death was the impaction in the œsophagus of a plate of gold containing an artificial tooth.

The Medical Superintendent of the Worcester Lunatic Asylum, Dr. Shelock, and his wife, were, a few days since, presented with a very handsome claret jug and an illuminated address, on the occasion of their silver wedding.

The New Orleans *Med. and Surg. Journal* says that so great is the intimacy between newspaper reporters and certain doctors "that one of the dailies of that city, contains from day to day, bulletins of cases of sickness in private families."

We understand that the lucrative appointment of Principal Medical Officer in India, held for some years past by Surgeon-General J. H. K. Innes, C.B., will be vacated by that gentleman in January next, his probable successor being Surgeon-General T. Crawford, M.D., now Principal Medical Officer in Ireland.

The executive committee for the memorial to Surgeon-Major Shepherd, who was killed at Isandula, whilst trying to save a wounded comrade's life, have resolved to present the senators of Aberdeen University (Dr. Shepherd having been born in that shire) with an annual gold medal for surgery.

The Duke Carl Theodor of Bavaria, a doctor of medicine of Munich, who presided over the Naturforscher-Versammlung at its meeting in Munich in 1877, has just published a scientific essay in Graefe's *Archiv f. Ophthal-*

Digitized by Google

mologie, entitled "Contributions to the Anatomy and Physiology of the Vitreous Body."

On Friday last Lord George Hamilton and Sir Francis Sandford, Secretary of the Education Department, visited the Royal College of Science, Dublin. It is understood that their visit is in connection with the reorganisation of that institution.

In the principal large towns last week the rates of mortality per 1,000 were—Portsmouth 14, Glasgow 14, Plymouth 15, Oldham 16, Edinburgh 16, Wolverhampton 17, Leicester 21, Bristol 21, Birmingham 21, Sunderland 21, Bradford 21, Nottingham 21, London 22, Salford 22, Norwich 22, Hull 22, Newcastle-upon-Tyne 23, Brighton 23, Sheffield 24, Leeds 24, Manchester 25, Liverpool 26, and the highest rate Dublin 31.

A munificent offer has been made by Professor Erasmus Wilson to the Court of Directors of the Margate Sea Bathing Infirmary for Scrofula, namely, to erect at his own sole cost a new wing containing wards for nearly seventy patients, a tepid sea-water swimming bath, and a chapel containing seats for 300 people. A resolution accepting with the warmest cordiality and gratitude this large-hearted act of benevolence, the cost of which will probably exceed £20,000, has been unanimously passed by the governors.

The Army Medical Service seems likely in the future to be a mixture of the Red Cross, the St. John Ambulance Association, with a mixture of Red Cross Pills, and a few army doctors to savour the mess. We are glad to notice the students are holding aloof. We wish that Poor-law medical officers had as much self-respect; if so, we would not hear of health officers at £10 a-year, or such out-pourings as find their way to our letter-box.

Dr. J. V. C. Smith died in Richmond, Massachusetts, on August 20. In 1823 he started the *Medical Intelligencer*, the first medical weekly in America. He has since been connected with the Boston *Medical Journal* and the *Medical World*, Mayor of Boston, Professor of Anatomy in Berkshire Medical College, author of the Natural History of Fishes of New England, and Treatise on Anatomy and Physiology of the Eye.

Mr. Mark Firth has signified his wish to found a Chair of Chemistry in connection with Firth College, Sheffield. He proposes to invest a sum sufficient to produce an annual income of £150, and this, together with the fees of students, will amount, it is believed, to a handsome sum. Mr. Firth proposes that the appointment shall be first filled by Dr. Carvelley, of Owens College, Manchester. Mr. Firth built the College bearing his name, contributing at the same time £20,000 towards the general endowment fund.

On Friday last Dr. Hardwicke held an inquest in Holborn on the body of Cornelius McCarthy, a costermonger, who met his death under somewhat singular circumstances. Some days previously deceased ate some fried fish. Next day he complained of pain in the throat, and went to a hospital. The surgeons endeavoured to dislodge some foreign matter from the larynx, but not succeeding the man went home, and died two days later. A post-mortem examination revealed the fact that a small fish-bone had penetrated the heart, causing death.

Another singular accident, resulting in death, occurred last week at Sherborne, in Dorsetshire. About four months ago a little boy swallowed a tin toy, which is used to produce the noise in imitation of Punch. This became so firmly embedded in the trachea, that all efforts to dislodge it proved abortive. It subsequently broke into pieces. These were removed, except a three-cornered detachment, which, revolving on its own axis, eventually caused death from suffocation.

In the principal foreign cities the rates of mortality, according to the most recent weekly returns, were—in Calcutta 26, Bombay 34, Madras 40; Paris 23; Geneva 17; Brussels 27; Amsterdam 21, Rotterdam 24; The Hague 24; Copenhagen 26; Stockholm 17; Christiania 19; St. Petersburgh 31; Berlin 25, Hamburg 25, Dresden 20, Breslau 22, Munich 38, Vienna 24, Buda-Pesth 33; Rome 33, Naples 26, Turin 21; Alexandria 36; New York 24, Brooklyn 22, Philadelphia 13, and Baltimore 18 per 1,000 of the populations.

The election of the Council of the Surgical Society of Ireland took place on Monday week last at the Irish College of Surgeons. In addition to the outgoing Council, who offered themselves for re-election, the following gentlemen presented themselves for ballot:—Mr. P. C. Smyly, Dr. E. H. Bennett, Dr. Roe, Dr. Swan, Dr. Swanzy, and Dr. Wheeler. On scrutiny of the votes, it appeared that the entire of the Councillors who sought re-election had been again placed in office with the exception of Mr. Stapleton, and that Messrs. Smyly, Roe, Bennett, and Wheeler had also been admitted to the Council.

Mr. Rawdon Macnamara, junior, has been selected by the Professors of the Royal College of Surgeons in Ireland to act as a Demonstrator of Anatomy in the College School. The newly-elected is the third Rawdon Macnamara who has taken a place in the College School, his grandfather having been a very distinguished professor in the College, and his father its present representative in the General Medical Council, and its Professor of Materia Medica. Mr. Macnamara has just relinquished the house-surgeoncy of the Alnwick Infirmary, and has received, on his departure from that town, a handsome presentation and address, in testimony "of the golden opinions he has won from the public at large and the patients under his care since his residence there."

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

Health of Edinburgh.—For the week ending Nov. 1st, the deaths were 65 in number, and the death-rate was 15 per 1,000. The birth-rate was unusually high. No death

Digitized by Google

from fever was recorded in the city, and no zymotic deaths occurred in the southern suburbs.

Death from Hydrophobia in Glasgow.—On Saturday, Nov. 1st, a death from hydrophobia was reported in the Camlachie district of Glasgow. It appears that as far back as July last, the wife of a hammerman, residing at Gallowgate, was bit by a bad dog. The wound, which was on the right hand, was cauterised immediately by a medical man, and appeared to have healed entirely at the expiry of six weeks. No evil effects were, therefore, anticipated. On Sunday, previous to her death, she experienced considerable pain in the region which had been bitten, and subsequently the sensation extended to the whole of her arm. The following Tuesday unmistakeable symptoms of hydrophobia manifested themselves. Drs. Miller, Leitch, and Muir, visited the poor woman, but their skill was unavailing, and she expired on Saturday morning. During the last four days of her life she suffered terrible agony, and refused to touch either meat or drink.

Health of Glasgow.—Glasgow continues to be exceptionally healthy. Some two months ago—for the week ending Sept. 6th—the rate, as we reported at the time, reached the low figure then unparalleled in the city's mortality statistics, of 15 (14.5) per 1,000 of the population per annum. Since then the rate, as could only have been expected at this season of the year, has generally shown an upward tendency. Last week, however, going down at a bound from 18 in the preceding, the minimum of 14.3 was reached, being 2 of a decrease as compared with the first week of September, and absolutely the lowest rate of mortality on record in the city's statistics. In the corresponding week of 1878, 1877, and 1876, the rate stood at 21.

Registrar-General's Returns.—The weekly return of births, deaths, and marriages in the eight principal towns of Scotland says that the death-rate during the week ending with Saturday, the 1st November, 1879, was 15·9 per 1,000 of estimated population. This rate is 3·7 under that for the corresponding week of last year, and 1·2 under that for the previous week of the present year. The lowest mortality was recorded in Perth, viz., 11·7, and the highest in Greenock, viz., 23·0. The mortality from the seven most familiar zymotic diseases was at the rate of 2·6 per 1,000, being 0·4 less than the rate for the last week. A slight increase occurred in scarlet fever. Acute diseases of the chest caused 77 deaths, being 7 less than the number recorded during the previous week.

Action against a Glasgow Doctor.—The action against Dr. J. S. Cummings, as before referred to, by a commercial traveller, for £500 as damages for injury alleged to be sustained through unskilful treatment and negligence, has been dismissed by Sheriff Lees, the sheriff finding no proof of the allegations. He finds the defender entitled to expenses.

Testimonial to Dr. Andrew Fergus, of Glasgow,—At a numerous meeting of ladies and gentlemen assembled in the Merchants' Hall, Glasgow, Dr. Fergus was presented with his portrait by Mr. Norman McBeth, and several articles of plate. The chair was occupied by the Lord Provost, who spoke in eulogistic terms of Dr. Fergus. The plate consisted of a solid silver tea and coffee set in the style of the Elgin Marbles, a case of 18 pairs of silver fruit knives and forks, a case of four silver fruit spoons, and four corner dishes. There was also a gold bracelet, set with pearls and diamonds.

A Dinner after the Ancients.—In the Latin *menu* given in our last under the above heading, "Ostrea coccisa frixa" should read "Ostrea *con*cisa frixa."

Obituary.

CHARLES EDWARD SMITH, L.R.C.P., L.R.C.S. Ed.

A Medical Hero.

Those of our readers who knew "Charley Smith of the 'Diana,'" will read with sincere regret the announcement of his early death. The history of that terrible winter in the Arctic Seas—never published *in extenso*, and but partially revealed in fragments—caused a deep throb of emotion throughout the profession. Deserted by the other whaling vessels, the unfortunate "Diana" of Hull was left amidst closing ice in September, 1865—without provisions, without winter clothing, without fuel. On Christmas Day the captain—Captain John Gravill—died of cold and exhaustion. Their spare spars, their boats, save one, were burnt to melt the ice for drink. In a little time half an oil cask per diem was the allowance of fuel; a biscuit and a half per diem their scanty ration, in the Arctic Seas in a winter of unwonted severity. As the only educated man among them, the management of the ship and crew, after the captain's death, devolved upon its doctor. An Essex Quaker, the surgeon manifested all the passive courage of his sect. He took his turn at the pumps, which were going day and night, the ship having received a severe nip in the ice. By his example he animated and cheered the crew to work at what seemed a hopeless task. Then scurvy broke out; and many of the enfeebled wretches, on their miserable dietary, died on slight effort. With their swollen, bleeding gums they mumbled their biscuit, and ran "their race with death," as Captain Allen Young has designated this memorable voyage. When the death-stricken vessel drifted into Ronas Voe, in the Shetland Isles, in April, 1866, only four men could stand. Of the crew of fifty-one men, the captain lay in an icebound grave, while nine corpses lay stretched on the deck, and four more of them died before the ship reached Lerwick. When the "Diana" entered the port of Hull, thousands of people assembled to greet the ill-fated vessel. Charley Smith was recognised as the master-spirit to whom were due the lives of the survivors—the safety of the ship. Modest, courteous, diffident, unwilling to speak of his own deeds, Smith found himself a recognised hero. His reception was more than enthusiastic. The profession *fêted* him in public. The Board of Trade presented him with a case of surgical instruments which cost £50, accompanied by a testimonial signed by the President, declaring that his services had been "generous, humane, and unwearied." The townspeople of Hull and the underwriters of Lloyds presented him with a testimonial, and a purse containing one hundred and eight guineas. Many months of illness and exhaustion followed this long and terrible strain; and it was some time before Smith could resume his studies. When he returned to Edinburgh, one and all, teachers and fellow-students, welcomed back the genial, pleasant youth whose experiences had been so dreadful, and who had borne himself so heroically. Nothing, however, could overcome his repugnance to any perusal of his diary with a view to publication. Scraps and fragments of his story occasionally fell from him, telling of what straits he had passed through, of what a tremendous tension he had endured. Not feeling equal to study, he resided with Dr. Moffat, of Dalston, near Carlisle, working as his assistant. A general favourite, full of genial humour, no mean poet, the pleasantest of companions, "Diana Smith" was known far and wide. During this time Sir Roderick Murchison induced him to join Mr. Lamont in a Polar expedition; and few who knew Smith will forget his descriptions of scenes in Spitzbergen. A keen naturalist, from his very childhood he was familiar with every beast and bird. When only twelve years of age he noted that the martins never builded their nests in the afternoon, but left their work to dry while they were engaged in search of food. After a year or two of comparative rest he resumed his medical studies in Glasgow, where "Diana Smith" won a reputation for earnest application. He made an excellent appearance for his diploma, and became house-physician to the infirmary, where his discharge of his duties was most exemplary. His clinical reports are described as "models of correct English and careful observation." After trying a practice in Durham, he gave it up, and went as surgeon in charge of the emigrant ship "Dunedin" to New Zealand, where he settled in practice at Otepopo. Here he soon gathered friends around him, and was beloved by the Maoris; he was made a magistrate, so great was the respect for him. He married, and had a

Digitized by Google

very extensive practice, when his health broke down. The final act, which completed what over-exertion had been only too successfully essaying, was diving in the harbour for the body of a drowned man, which after repeated efforts he succeeded in recovering. A life of self-sacrifice culminated in this effort, and a severe ulcer of the stomach followed the exposure. He disposed of his practice, and came home with his wife and child, in the hope that this would restore his health—in reality to die. Worn, wan, wasted, waxen—he met death calmly and composedly, as he had faced it many a time and oft before. The old man, the playful humour passed away, and religious convictions took their place. Quietly, in his Essex home, the wanderer went to his rest in peace. After all his perils in various parts of the globe, "Diana Smith" died in bed under his father's roof-tree in September last, leaving the sorrow-stricken old man to furnish what comfort he could to the girlish widow and her fatherless boy. To this boy he has left the manuscript diary of that fearful winter in the Arctic Seas. Many will regret that he has thus prevented the publication of the record of his sufferings and his heroism until they will be well-nigh forgotten; for one and all of his hundreds of friends would have been glad to possess, in the form of a book, a memorial of a man who did honour alike to his profession and to humanity.—*Edinburgh Medical Journal* for November.

Correspondence.

VACCINATION AND RE-VACCINATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The severe nature of the small-pox epidemic which visited London during the autumn of 1876, and prevailed with more or less intensity during the whole of 1877 and 1878 and part of 1879, induced the Managers of the Metropolitan Asylums District—upon whom, in their official capacity, devolved the treatment of a large proportion of the infected—to collect certain statistical facts which illustrate the advantages of efficient vaccination and re-vaccination, as evidenced by the experiences of the medical superintendents of the several small-pox hospitals under the control of the Board.

The observations of these gentlemen confirm former opinions on the subject, and establish beyond doubt the mitigating influences in small-pox cases of successful primary vaccination, and the preventive powers of efficient re-vaccination.

The total number of small-pox patients treated in the various hospitals of the managers, from the outbreak of the epidemic in 1876 until the commencement of the present month, has been 15,171, of whom 11,412 were vaccinated, and 3,759 unvaccinated; and it is believed that for each case treated in the Board's Hospitals, another was privately attended—hence some idea may be formed of the magnitude of the epidemic.

The total number of deaths which occurred in the hospitals during the period under consideration was 2,677. Of these 1,008 were vaccinated, and 1,669 were unvaccinated cases. The percentage mortality upon the whole of the admissions was therefore 17·6, being at the rate of 8·8 per cent. of the vaccinated, and no less than 44·4 per cent. of the unvaccinated.

It may be observed that, among the 11,412 vaccinated patients admitted, are included the majority of those who stated that they had been vaccinated, but upon whom no traces of vaccination were discernible. No case of small-pox has come within the cognisance of either of the medical superintendents of any person who had been efficiently vaccinated and successfully re-vaccinated. The nurses and servants employed from time to time at the various hospitals during the epidemic, have enjoyed almost absolute immunity from infection, and the few, some half-dozen amongst nearly one thousand—who contracted the disease whilst discharging their duties, had, from some cause or other, escaped re-vaccination before entering the wards. Experience has therefore irrefutably proved that, were vaccination efficiently performed in infancy, within the period prescribed by the Vaccination Act, and re-vaccination successfully accomplished at puberty, small-pox, instead of being, as it is at present, a common and extremely fatal disease, would be a comparatively rare one, and so little fatal that few, if any, deaths would result from it.

Yours, &c.,

W. F. JEBB, Clerk.

The Metropolitan Asylums Board Offices,
37 Norfolk St., Strand.

VACCINATION AND ITS SUPPOSED DANGERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Referring to the excellent letter of Dr. Whistler in your columns of this date, and to your own question—Whether any disease is ever communicated by vaccination other than vaccinia? I trust you will permit me to make a few observations.

In Dr. Ballard's prize essay on vaccination the reader can find unmistakable evidence that syphilis may be conveyed from one child to another by vaccination, and in the pages of the *Lancet* and other medical journals from time to time further evidence is offered. I am not aware that any medical man who has studied the literature on the subject denies these facts.

Some time ago, in speaking on this subject to a well-known physician he replied—"A family, relatives of my own, had themselves and their servants re-vaccinated during the recent epidemic of small-pox, and everyone so re-vaccinated showed afterwards a secondary syphilitic rash." A few days afterwards I mentioned this statement to another well-known physician, and he replied—"A patient of mine recently got re-vaccinated, and he came to me afterwards and showed me his arm, whereon I saw, at the spot where the operation had been performed, a chancre."

Pure vaccine lymph, being a specific, cannot convey any disease but vaccina; but if there exist any blood corpuscles mixed with the lymph, then that lymph may convey syphilis. Rashes of various kinds frequently show themselves among the poorest classes after vaccination, but no doubt, in the great majority of cases, these are the result of a fermentation bringing latent disease to the circumference.

For two years I have been engaged in producing calf vaccine lymph and distributing it to the profession. About 5,000 (five thousand) cases have been so vaccinated with that lymph, the success, so far as I can ascertain, being, in infants, about 80 per cent.

As I consider the lancet may convey blood from one case to another, I advise the use of large American lancet ivory points, each used for one child only. It is not so easy to vaccinate thus as with liquid lymph and the lancet, hence the percentage of failures is accounted for; but with myself, I have during two years had only *one* failure in infantile vaccination. The method is not so convenient for medical men, but as all classes of society, from the very highest to the very lowest, and especially the operative class, prefer calf lymph, I do trust, with Dr. Drysdale, that our Government may be induced to inquire into the matter.

The duty I have imposed upon myself is an anxious, laborious, and expensive one, and I shall at any time be only too glad to surrender my position, and to place before any commission all the practical information I possess on the subject. Until Government, however, relieves me of my responsibilities, I will do my best to supply the profession with calf lymph, as a complete answer to all objections against vaccination.

Yours truly,

GEO. WYLD, M.D.

November 5th.

ST. JOHN'S HOSPITAL FOR SKIN DISEASES.

The following letter addressed to the Council of the Charity Organisation Society has been sent us for publication:—

GENTLEMEN,—I have the honour to call the attention of the Charity Organisation Society to St. John's Hospital for Diseases of the Skin, Leicester Square, W., which claims support as one of the public charitable institutions of the metropolis, and therefore invites public investigation.

I was lately one of its honorary medical officers, but in no way responsible for, or cognisant of, its management. In that position several matters came casually under my notice against which I protested. At the desire of the Committee I

Digitized by Google

put my allegations into writing, and some of these I now beg to lay before the Charity Organisation Society. I shall address myself only to the financial questions, which I apprehend solely concern the Charity Organisation Society, and with that view I shall first quote verbatim the following extract from my written statements to the Committee of St. John's Hospital :—

"The position of the hospital from a charitable point of view is peculiarly unsatisfactory. While its collecting boxes at railway stations and on drawing-room tables ostentatiously inform all that *sickness pleads for succour*, are contributors aware that the numerous out-patients pay on an average about a shilling a week, and does the Hospital Saturday Fund, which will not contribute to provident dispensaries, as they hold this to be paying twice over, know this when they give high marks and contributions to St. John's Hospital? Does the medical profession know that, while the medical staff receive nothing, some out-patients pay two, three, and even five shillings a visit, the honorary medical staff being thus made to cut the ground from underneath the feet of outside general practitioners?

"Is it not a fact that, to the intense disgust of the honorary medical officers, the board advertised last year for middle class patients, from whom the sum of five shillings per visit was demanded, my first patient of the kind being an American tourist living at the Langham Hotel, who claimed the benefit of the advertisement, in accordance with which I had to prescribe for him? Is it not a fact that from two to three pounds were thus received lately on each occasion of my seeing the out-patients, I being but one of three who see out-patients on the same day, and are not from four to five pounds received during the hours of attendance of another medical officer?

"The above merely gives an idea of the income of the hospital from out-patients' fees. Two of the seven medical officers brought in £10 a week at least from that source alone, and my last two in-patients paid, one at the rate of ten shillings a week for nine months, and the other one pound a week for some months. But if we return to the last printed report of the hospital, at page 9 we find that the number of out-patients for the year 1877 is put down as 23,540, which, according to my estimate of a shilling a visit, ought to have yielded £1,175, and my estimate may be verified on the medical officer's register of out-patients. But the amount received from patients (including both out and in-patients) for not merely the twelve but for the fifteen months between October 1st, 1876, to December 31st, 1877, is put down at page 14 as £299 16s. 7d. The amount, according to my estimate, ought to have been five times as much, and the serious question is, what has become of the balance?"

I may add that my statement concluded with the words "If the board are unwilling to institute the necessary reforms I shall be content to see this letter distributed broadcast as the justification of my action, or to submit the questions I now raise to the Charity Organisation Society, by whose decision I am willing to abide."

I had thought that the board of St. John's would have only been too glad to have the imprimatur of the Charity Organisation Society, whose avowed function is to promote the co-operation of honest charities; but in this I was mistaken, for instead of their consent I received a letter from their solicitor threatening me with a prosecution for libel if I did not completely withdraw all the statements I had made (*at their own request*) and fully apologise for my conduct.

Instead of doing this I invited them to carry out their threat, and they replied that they would not prosecute me at present, but dismissed me from all connection with the institution as if it were either an advantage or an honour to be connected with it.

Farther, it is to be considered that, not only is the hospital cutting the ground from beneath outside practitioners by vending that for which it pays nothing, but it is enabled all the better to do so from the large subsidies it receives from the Hospital Saturday and Sunday Funds.

On the 29th of July last the Sunday Fund made a grant of £50 10s. 5d. to St. John's Hospital, and the very next day the secretary sent out letters to the contributors to the hospital announcing the fact as showing "how great progress in efficiency it had made."

As the subscription from private contributors in the year 1877 purports to have been double all other sources of income of the hospital (see page 14), the result of such a subsidy used as an imprimatur of character and efficiency must be disastrous for the private practitioner who has to meet such heavily subsidised competition. And the Hospital Saturday Fund will, I presume, be the next to give it imprimatur and subsidy if the Charity Organisation Society does not give some note of warning on the subject.

I shall be glad to suggest to the officers of the Society how further information may be obtained on the points I have referred to. In submitting the above case to the Charity Organisation Society, as one which merits its best attention,

I have the honour to remain, gentlemen, your obedient servant,

GEORGE HOGGAN, M.B.

7 Rutland Gate, London, W.

THE UNIVERSITY OF DURHAM DEGREES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—A correspondent in your issue of the 29th of October, who signs his letter "A Word to the Wise," seeks for information respecting the Medical Faculty of Durham University. As that gentleman seems to imagine that the race of medical graduates of that University is extinct, the following facts may serve to convince him to the contrary. About three years ago certain changes were made in the regulations for the M.B., which placed that degree within the reach of students of other schools on condition of one year's residence; since then the number of candidates, and consequently graduates, has steadily increased.

At the last meeting of Convocation ten gentleman graduated in medicine, two of whom held the diploma of F.R.C.S. England. Since the 1st of October last year, thirty-six gentlemen possessing qualifications in medicine, many already doubly qualified, have entered for the necessary year's residence, and four candidates in addition have presented themselves, within the same period, for examination for the degree of M.D. without residence, granted to practitioners of fifteen years' standing and forty years of age.

Should your correspondent require further information on this subject I can only refer him to the prospectus of the University of Durham College of Medicine.

Yours, &c.,

A MEDICAL UNDERGRADUATE OF THE UNIVERSITY OF DURHAM.

7th November.

INTRA-UTERINE MEDICATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have found the following simple arrangement for intra-uterine medication answer very well :—Cut the end off a flexible No. 10 catheter, pass the wire stilette through it, and make a knob on the end of it with wax and cotton wool, which will just cover the end of the catheter; then push up the stilette about an inch and a-half, roll cotton wool round it, and dip it in the solution to be applied (carbolic acid and iodine is excellent), and draw it within the catheter so that the knob just covers the end, give it a bend like a uterine sound, and pass it up to the fundus of the uterus; then draw the catheter down the wire. This, of course, brings the medicated cotton wool in contact with the uterus through its whole length. After leaving it in for a minute or two, it can be withdrawn. The speculum is not needed. The main recommendation of this arrangement is that it saves the cost of a 20s. or 25s. instrument, an important matter in these times.

Yours, &c.,

ALEXANDER WALLACE, M.D.

Parsonstown, Oct. 29, 1879.

Important Meeting of Medical Men on Water Contamination.—A few weeks since we called attention to the decided stand made by Dr. Hime, the medical officer of health for Sheffield, against the contamination of the water supplied to the town by sewage, and by the continued building in of the dam whence the town supply came. At a meeting held on Saturday last, convened and presided over by the Mayor, the following gentlemen were present :—Drs. Bartolomé, Banham, Hime, J. Young, Law, W. Dyson, and W. E. Thomas; and Messrs. J. Barber, Edward Barber, Olliver Barber, Taylor, Hargreaves, W. Favell, A. Jackson,

Digitized by Google

Snell, Martin, Packman, Ed. Cooke, Benson, Leach, M'Beath, Davidson, James, Skinner, Pye-Smith, Adams, Morton, Cleaver, Shera, Inkster, and Thorpe. The meeting was most enthusiastic, and it is gratifying to notice that the Mayor was at one with the profession upon this vital question. Resolutions were passed condemnatory of the system of over-building around, and drainiage into, the dam; and Dr. Hime's hands were further strengthened by the unanimous support and thanks of his brother practitioners for his zealous and determined action in the matter.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

CANDIDATES FOR THE ARMY MEDICAL SERVICE are informed that the next examinations for admission to this department of the public services will be held in London at the Law Institution, Chancery Lane, on December 8, and following days. Particulars as to applications will be found in our advertisement columns.

MR. NEWMAN.—With much pleasure.

THE METRIC SYSTEM.

As we are frequently asked for information on the metric system, we shall publish the annexed and other tables from time to time, with the view of assisting our readers in what is rapidly becoming a difficulty, in consequence of the frequent use of the metric notation by writers, both in our own and other journals:—

METRIC MEASURES OF LENGTH.

Millimetre	0·001	of a Metre	equals	0·03937	inch
Centimetre	0·01	,,	,,	0·39370	,,
Decimetre	0·1	,,	,,	3·93707	,,
METRE	1	METRE	,,	39·37079	inches
Decametre	10	Metres	,,	393·70790	,,
Hectometre	100	,,	,,	3937·07900	,,
Kilometre	1000	,,	,,	39370·79000	,, (1 mile)
5 Kilometres	..	...	equals 3 miles		

METRIC MEASURES OF WEIGHT.

Milligramme	0·001	of a gramme	equals	0·015	grain
Centigramme	0·01	,,	,,	0·154	,,
Decigramme	0·1	,,	,,	1·543	,,
GRAMME	1	GRAMME	,,	15·432	grains
Decagramme	10	Grammes	,,	154·323	,,
Hectogramme	100	,,	,,	1543·234	,,
Kilogramme	1000	,,	,,	15432·348	,,

454 Grammes equal to 1 lb.

METRIC FLUID MEASURES.

When using the metric system, fluids are preferably prescribed by weight, employing the gramme, its multiples and sub-divisions, just the same as with solids, thus avoiding the errors due to refraction, adhesion, and inaccurate measuring vessels.

For practical purposes, four grammes of water may be regarded as equivalent to a fluid drachm of that liquid. And the same may be considered true of tinctures and infusions. Syrups, on the average, are about one-third heavier than water, so that a fluid ounce of a syrup will be approximately represented by 43 grammes. Fluids may be prescribed by volume in the metric, just as in the present system, using for that purpose the cubic centimetre, that is a volume represented by a cube, all of whose sides measure one centimetre.

One cubic centimetre (C.C.) equals 16·231 minims. It is approximately regarded as one-fourth of a fluid drachm.

Mem.—Approximate weights of 20 drops of the following:—

	GRAMMES.	GRAINS.
Ether Sulphuric at 66 deg.	0·35 equal to	5½
Liq. Hoffman	0·45 ,,	6¾
Alcohol at 80 deg.	0·45 ,,	6¾
Oil of Almonds	0·55 ,,	8¼
Acid Acetic at 10 deg.	0·60 ,,	9
Essential Oil of Peppermint	0·65 ,,	9¾
Distilled Water	0·75 ,,	11¼
Laudanum	0·70 ,,	11
Acid Sulphuric, 60 deg.	1·20 ,,	17⅞
Syrups at 35 deg.	1·50 ,,	23

MR. E. HAWKER.—Not suitable for our columns; we have directed our publisher to return the MS.

A MEMBER OF THE COLLEGE.—A "storm in a teapot."

FOREIGN HEALTH RESORTS IN LUNG DISEASES.—Several letters on this subject are unavoidably held over from press of matter.

MR. HEMMING.—If possible in our next.

AN ANXIOUS ONE.—Quite out of print.

DR. T. H. WILLIAMS, New York.—Thanks for your complimentary remarks; we shall endeavour to merit a continuance of the good opinions of our American *confrères*.

DR. C. CROSSMAGHER.—Write to Dr. George Wyld, 12 Great Cumberland Place, Hyde Park, London, W.

DR. BALMANNO SQUIRE.—Communication will appear in due course. We are much pressed for space just now.

ZOOLOGIST.—The lectures now being delivered at the British Museum every Thursday and Saturday by Dr. Carter Blake will help you to a practical appreciation of the subject.

F.R.C.S.—We have carefully weighed the reports on both sides, and think it better not to give it the prominence of publicity in our columns.

"DEMAND FOR ARMY DOCTORS.

"(*Don't they wish they may get them?*)

"WANTED, for employment as medical officers in the British army, an adequate number of thoroughly well-educated physicians and surgeons, willing, on occasion, to expose their lives to the utmost danger in active service, without any expectation of receiving the Victoria Cross, or being otherwise distinguished or rewarded. They must have no objection to put up with indignity and neglect, be contented with an amount of pay not exceeding a sufficiency for their daily maintenance, and be prepared on their discharge to depend for their subsistence upon such private practice as they may hope to pick up by beginning the world again late in life. As the want of competent army physicians and surgeons is just now very urgent, the supply being far from equal to the demand, immediate applications are confidently expected at the War Office."—*Punch*.

A QUACK'S EXODUS.—The State Board of Health for Massachusetts, in their tenth Annual Report, direct the attention of the State Legislature to the experience of Illinois, where, in one year and a-half, 1,400 self-styled doctors are reported as having left the State, because they were unable to pass the examinations required of them. Of these, 400 are estimated to have gone to Indiana, 250 to Wisconsin, 100 to Minnesota, and an unestimated number to Missouri.

MR. WENHAM.—Your letter, with editorial comment, will appear in our next.

MR. T. M. D.—Letter on Superannuation will appear in our next.

CLINICAL SOCIETY OF LONDON.—On Friday, Nov. 14, Dr. Crocker, A Case of Congenital Sebaceous Disease of the Scalp; Mr. Spencer Watson, A Case of Acute Ophthalmitis affecting both Eyes—Treatment by Rapid Mercurialisation, and the Instillation of Duboisin; Surgeon-Major Alcock, A Case of Perforating Wound of the Lung; Mr. Norton, A Case of Removal of the Frontal Bone, Left Wing of Sphenoid, Ethmoid, large part of the Superior Maxilla, and one Eye, with complete restoration to health (patient exhibited); Dr. Goodhart will exhibit a Case of unusual Development of Keloid in Small-pox Scars; Mr. Balmanno Squire will exhibit a Case of Port-wine Mark cured at two Operations by Linear Scarification; also a Calotte after use in the treatment of Ringworm.

VACANCIES.

Abbeyleix Union, Ballyroan Dispensary.—Medical Officer. Salary, £100, with fees, and £20 as Medical Officer of Health. Election, Nov. 18.

Belmullet Union, Bangor Dispensary.—Medical Officer. Salary, £100, with fees, and £10 as Medical Officer of Health. Election, Nov. 17.

Gort Union, Gort Dispensary.—Medical Officer. Salary, £120, with fees, and £10 as Medical Officer of Health. Election, Nov. 22.

Royal Free Hospital, London.—Assistant Surgeon on the Staff. Applications to the Secretary on or before Nov. 26. (See Advt.)

APPOINTMENTS.

CASLEY, R. K., M.D., Honorary Physician to the East Suffolk and Ipswich Hospital.

CHISHOLM, J. M., M.A., M.B., C.M., M.R.C.S.E., Resident Surgeon to the Royal Infirmary, Edinburgh.

HUTCHESON, G. W., M.D., M.R.C.P.E., Medical Officer for the Chipping Norton Workhouse.

JACKSON, M., M.R.C.S.E., Medical Officer for the No. 2 District of the Chipping Norton Union.

LOVEROCK, R. G., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer, &c., for the Termon Dispensary District of the Bailieborough Union, co. Cavan.

LYON, Dr. J. A., Medical Officer and Public Vaccinator for the Parish of St. Andrew's, Fifeshire.

MCALPINE, A. N., B.Sc., Lecturer on Botany at the Minto House School of Medicine, Edinburgh.

OLIVER, T., M.B., Lecturer on Practical Physiology in the University of Durham College of Medicine, Newcastle-on-Tyne.

WILLIAMS, P. St. G., M.R.C.S., Assistant House Surgeon to the Huddersfield Infirmary.

Deaths.

CONNOR.—On Oct. 31, at Knockmaroon, St. John's Hill, New Wandsworth, William Connor, M.A., M.B., F.R.C.S.I., aged 75.

DAWSON.—On Oct. 28, at Thames Ditton, John Dawson, M.R.C.S.E., aged 72.

FOX.—On Nov. 5, at Brook Street, London, W., Hy. Hawes Fox, M.D., late of Northwoods, Gloucestershire, aged 60.

MORTON.—On Oct. 31. at Bideford, Augusta, wife of Dr. J. S. Morton, Surgeon-Major Madras Medical Service (retired), aged 50.

ROBERTS.—On Oct. 31, Eliza, widow of C. J. Roberts, M.D., aged 82.

SCOTT.—On Oct. 29, at Bryn, Conway, William Joseph Scott, M.R.C.S., aged 32.

SHORT.—On Nov. 1, at Beech Lodge, Harrogate, Wm. Short, L.F.P.S.G.

TORNEY.—On Nov. 1, at Ellis's Quay, Dublin, Richd. Torney, L.R.C.P., aged 48.

PSYCHOLOGY AND THE NERVOUS SYSTEM.

By J. HUGHLINGS-JACKSON, M.D., F.R.S.,

Physician to the National Hospital for the Epileptic and Paralysed, and to the London Hospital.

(*Concluded from page* 411.)

We returnn ow to consider further differences betwixt ideation and perception, which will enable us to see more clearly that the demarcation betwixt subjective and objective activity is not so rough as we represented it to be.

So far we have implied that the differences betwixt ideation and perception are doubly compound—that there is not a difference in faintness and vividness only nor in feeble and strong reference to the environment only but in both. There is a further difference. The greater the ideation the more are the images which constitute it associated with our already organised images (or, in popular language, the more are they part of an ideal environment). This is admitting that there is no abrupt division betwixt subjective and objective activity, for the more mentation is made up of images organised in us the more subjective it is. The subjective stage ceases into the beginning of the objective stage—ideation. The greater the perception the less are the images constituting it associated with (that is more dissociated from) our already organised images, and the more associated are they with those now organising from the environment—in popular language, they are part of an actual environment. (We think not only by the Association but by the Dissociation of ideas). In brief, the greater the ideation, the less the perception; the greater the perception, the less the ideation; greater or less, in the triply-compound degrees of (1) differences of degree of faintness and vividness of the images particularly constituting the mentation of the moment, (2) differences of degree of association of these images with already organised, and of degrees of association with now organising images, and (3) degrees of feeble and strong reference to the environment. (*a*)

These statements as to differences seem to me to harmonise with the speculation as to the differences in the correlative physical discharges. The highest centres being most differentiated will be those with most numerous "cross," or "lateral," lines of integration. When nervous discharges of parts of the highest centres are slight, as during ideation, they will only be able to overcome the resistances, to discharge other parts of the highest centres, but not able to overcome the resistance of subordinate centres. They will be confined to the highest centres. Wide spreading discharges throughout the highest centres are the physical side of association with formerly organised states. When discharges of the highest centres are strong, they will be able to overcome the resistance of —to discharge—the subordinate centres. When discharged the lower centres are *then* lines of least resistance; the currents will then "flow" more downwards, and less laterally; and thus the ideation (association with formerly organised states, &c.), will be less, and the perception (association with now organising states) greater. It is significant that the subordinate centres contain more large cells than the highest centres.

This speculation seems to me to accord with the facts of epileptic seizures. I speak of the seizures which begin with loss of consciousness, or in which consciousness ceases very early, and mostly after a "warning," which we may declare to be consciousness ceasing. It is very common for a patient to have the slight attacks called *le petit*

(*a*) Of course, although speaking of the organised and the organising, we admit innumerable degrees of organisation from the most deeply and permanently organised (as, for example, the respiratory nervous arrangements) to the most slightly and temporarily organised (as, for example, those concerned in what we saw a moment ago). Moreover, we consider organisation in two ways. A process is organised the more the nervous arrangements for it are strongly or frequently discharged so far the more is it independent or differentiated from the rest of the organism. But those nervous arrangements are also organised along with others, and indirectly with all others; so far it is dependent on and integrated with the rest of the organism. The two kinds of organisation correspond to what on the psychical side are objective and subjective.

Digitized by Google

mal long before he has *le grand mal*. The thing I wish to point out is that he does not, the rule is, become subject to *le grand mal* by having seizures of intermediate degrees of severity; but some unfortunate day he has a severest seizure. I believe that in the stage of *le petit mal* the discharges are nearly confined to the highest centres, and that when the big fit comes they have become strong enough to overcome the resistance of the subordinate centres. (*a*) The speculation accords with the general opinion of alienist physicians that the slight fits are worst for mind; it is, in terms of my hypothesis, bad for the discharge to be confined to the highest centres. It is better for them to "get out" through the lower centres.

There is a more direct bearing of the hypothesis. In some cases of slight epilepsy the patient has during the ceasing of object-consciousness (or simply when he is forgettimg what he is doing and where he is) an increase of subject consciousness (or simply ideas rise up in his mind, and necessarily, be they what they may, of what has been organised in him). Now he remembers this "dream," or at any rate, remembers that he did dream. In some cases of epilepsy, after the paroxysm, the patient acts; if so, the rule is, that he does not remember anything of the actions. (This is analogous to what has been affirmed of dreaming and somnambulism.) In the former case I submit the lower centres are not, and in the latter are, overcome. To remember a thing well is to have it firmly associated with other psychical states, which are fully organised. In some cases there is, during the onset of the paroxysm, the "dream," this being remembered; and after the paroxysm, there are actions of which the patient knows nothing. I hope, however, sometime to be able to show that the actions in these cases are in accord with the "dreamy" state. One patient's dreamy state during the onset is a feeling of "being somewhere else;" his unremembered actions are apparently those of trying to escape —"he makes for the door," as his father puts it.

I think also that some curious states in dreams are explainable on resistance of lower centres to the higher. Some people dream that they cannot do something they earnestly wish to do—cannot, for an example, dress when naked under awkward circumstances. I believe this is because the discharges corresponding to the ideation (incipient action) are not strong enough to overcome the lower centres; when they do the patient awakes, or perhaps is somnambulistic.

Thus, then, as we said, the distinction is not abrupt into subjective and objective states. A state is the more subjective the more the leading images of it are associated with other already organised images; it is the more objective the more it is associated with other images now organising.

Under another aspect all mentation is a rhythm of subjective and objective states. In morbid mentation there is defect of the objective process, and an increase of the subjective; the rhythm goes on at a lower level. This is equivalent to saying that the symptomatology of mental diseases is duplex; there is a negative, and there is a positive—indeed, an hyperpositive—element.

There is no such thing as a purely subjective or a purely objective state.

Let us take a case of morbid mentation. When more or less of the highest centres are *hors de combat* in dreaming, in delirium, &c., the rhythm of subjective and objective action goes on at a lower level. In delirium, the more organised images take the place of the less, the now organising; what in health are objective states being lost, what is in health subjective becomes then objective, there being a still lower subjective stage. There is a veritable deepening of consciousness—with diminishing object consciousness there is increase of what in health is a subject consciousness—then the images, particular and collateral, which in health subconsciously precede the images, particular and collateral, of objective states, are final, and for the patient quite real. A patient of mine, with some cerebral atrophy, in the London Hospital, complained that the man in the next bed got up and cut a round piece out of his blanket, as big as the top of a hat. I asked him why he believed that. He replied: "Because I saw him." A delirious *cabman*, standing by his bed, asked me to get into his cab, and to tell him where he should drive me. I asked, "Where is your cab?" He replied with a sneer which plainly meant what a fool you must be, "Why here!" pointing to his bed. Another patient of mine told me that his friends had brought him two birds, and had left the cage. I asked to see the cage, on which he brought the wire-work case for bottles affixed to his locker. I told him that it was not a cage. He admitted that it had lost its top. Another patient said to me when I went up to him: "I've brought this bale from the gateway, and want two shillings for it." The bale was a blanket wrapped up, and he was in a private room in the hospital. I wish to urge that these patients saw those things they spoke of, that the cabman saw a cab when we saw a bed. The bed developed in him the image of the big thing most organised in him. It was inferior perception. To wonder why he did not see it as a bed as we did is like wondering why the Esquimaux did not see glass as glass.

(*a*) The expression, "nearly," may seem to render the statement too vague. But I think it is not vague when we simplify it by saying that parts in which small muscles serve, parts chiefly concerned in emotional manifestations, are those effected by the discharge during *le petit mal*. My impression, indeed, is that many fibres, representing those parts chiefly concerned in emotional manifestations, pass from the highest centres, without break, by entering into—joining the cells of—the lower cerebral centres. Instead of small muscles, we should in strictness say, "movements which require little energy for the displacements they have to effect." Epileptic seizures begin by spasm of small muscles. I believe that small muscles are most represented in the highest centres, which is equivalent to saying that the hands and ocular muscles are largely represented therein; the nervous arrangements which are the motor substrata of tactual and visual ideas represent these parts.

PAUPERISM AND DRINK, WITH SOME REMARKS ON THE MEDICINAL VALUE OF ALCOHOLIC BEVERAGES AND THE MORTALITY FROM ALCOHOL IN WORKHOUSES.

By THOMAS M. DOLAN, F.R.C.S.Ed., L.R.C.P.E., &c.,
Medical Officer Halifax Union Infirmaries.

(*Continued from page* 413.)

II.

But there is another side to this custom of allowing beer to pauper inmates. In the course of my reading temperance literature, I have come across some very striking testimony as to the association of drink with pauperism; and one of the general arguments against employing alcohol in workhouses is, that as the majority of the inmates are admitted through drink, consequently alcohol should not be given, in any form, to gratify the passion which has led to dependence and pauperism.

The Rev. J. Holt, Chaplain to the Birmingham Workhouse, writes:—

"From my own experience I am fully convinced of the accuracy of a statement made by the late Governor, that of every hundred admitted, ninety-nine were reduced to this state of humiliation and dependence, either directly or indirectly through the prevalent and ruinous drinking customs."

Mr. Carlton, a guardian, states:—

"I have been a guardian for thirty years. I have never met with a single teetotaller who has come to our workhouse. We examined 108 females, and found 106 had come to the workhouse through drink."

A Mr. Mott observed 300 cases in Lambeth Workhouse. He found "in nine cases out of ten that the main cause for their pauperism was an ungovernable inclination for spirituous fluids."

Such testimony is very striking, and cannot be idly

Digitized by Google

put on one side. It seemed to me worthy of inquiry whether drink was the main factor in filling the Halifax Workhouse; and I have endeavoured to find out whether my sick wards were crowded with old drunkards in the proportion of ninety-nine per cent.

The first difficulty was to arrive at accurate information and the method I had to adopt was not quite so satisfactory as I could wish; and hence, perhaps, a certain percentage must be written off for sources of error. My information, as to the habits of the patients, was obtained by two methods—direct and indirect—

1st. From the confessions of the persons themselves, which were generally very candid; and

2nd. In an indirect manner, from inquiries from persons who knew the individuals in other circumstances of life; whilst the appearance and diseases also afforded a certain standard of comparison, with the statements volunteered or collected.

I tried to free my mind from any bias, whether for or against alcohol, so that I might draw up an impartial report, which would tell its own tale without any interpretation.

I have drawn it up in a tabular form, showing sex, age, state of patient—whether married or single, disease and habits, temperate, moderate, intemperate.

As I have said, sources of error must be allowed for, as it was impossible to collect information as to the indirect influences, which led to the pauperism of the female patients. Thus many women may have been reduced to destitution by the intemperate habits of their husbands, or by the early death of the bread-winners from alcoholic excess.

Another consideration also arises, even assuming complete temperate habits. Is it possible for out-door labourers, with wages averaging from 10s. to 24s., to make provision for possible contingencies, as illnesses, arising from the very nature of their employment—such as rheumatism, bronchitis, inflammation of the lungs, phthisis, ulcers of the leg, and the rest—or for women, with lower wages, to save for the proverbial rainy day.

In the case of drinkers, would the amount of money expended be sufficient, if it had been saved, to provide an annuity for not only old age, but for sickness? (*a*)

Calculations of this nature must be entered into when dealing with the drink question, but as a rule they are

(*a*) The Rev. L. Lowry Blackley has suggested a scheme for "National Insurance" to remedy the evils of pauperism, and in the July number of the *Contemporary Review*, 1879, under the heading "Compulsory Providence as a Cure for Pauperism," he further advocates and defends his proposal.

overlooked, and still more whilst the evils of intemperance are continuously harped upon, the causes which have led to excess are completely forgotten, so that in the well-meaning efforts of temperance reformers there is a tendency to begin at the wrong end. I do not expect any great social amelioration, either in respect to drink or pauperism, until more attention is paid to the dwellings of the poor, and to the sanitary condition of their surroundings—though I mean more by sanitary, than what is conveyed by our ordinary conception of the word, for I include under it the moral influences arising from education, and still more from religion.

The pertinacity with which some members of boards of guardians insist on the uselessness of alcohol in workhouses, and on the necessity of medical officers conducting their practice on strict teetotal principles, seems to me, though very praiseworthy, as evidence of consistency, yet, nevertheless, as so much misplaced energy, which might be expended to a better purpose. It is right that guardians should exercise some control over their medical officers, and when the quantity of alcohol used seems excessive that they should inquire the reason for its administration. This might be done by consulting the medical officer, and by making a bed-side visitation with him. Thus the guardians would see each individual, and would understand from the explanation of the medical officer, both the quantity administered to each patient and the nature of the disease. There can be no doubt that this would be a more satisfactory method than the one adopted, of periodically protesting in the name of teetotalism, whenever a few gallons of alcohol are placed on the workhouse order-book. In the true interests of temperance I submit that my plan, as suggested,

would be more productive of advantage and satisfaction to all concerned, and "the thin end of the wedge" would be more likely of introduction.

The interpretation of the foregoing tables I leave to my readers.

Formerly Ophthalmic and Aural Surgeon to the City of Dublin Hospital and Dublin Eye and Ear Infirmary.

(Continued from page 395.)

Ossification of the Crystalline. (*a*)

The possibility of true ossification of the crystalline lens is to the author an acquired fact, as he has had occasion to enucleate an eye and to examine the crystalline, which was exceptionally hard.

The microscopic examination was made by Dr. Cutler, a distinguished micrographer, and proved most emphatically the existence of true ossification, characterised by the canals of Havers and concentric layers of osseous corpuscles.

On the Law of Duration of Impressions in the Eye. (*b*)

At the present moment, when inquirers recur more and more frequently to the hypothesis of fatigue of the retina as an explanation of consecutive images, it may not be inappropriate to recall to mind that, even before Fechner and Helmholtz had developed, with full details, Scherfer's theory on the subject of fatigue of the retina, M. Plateau, basing his statements on numerous ingenious and even celebrated experiments, had already fully elaborated an opposite theory, which referred the phenomena of consecutive images to a particular mode of reaction of the retina. The well-known *savant* of Ghent has suffered severely, by loss of sight, for the interest he has ever taken in this branch of optical physiology. Turned aside for several years from these studies, but not discouraged, he again pursues them by borrowing—so to speak—the eyes of some of his surrounding friends, as is testified by two publications in which he defends, in part with fresh experiments, his former hypothesis on the subject of accidental images and of irradiation.—(*Bulletin de l'Académie des Sciences de Belgique*, 2me série, t. xxxix., 1875, p. 100 ; and t. xlii., 1876, pp. 335 and 684.)

Not content with defending his former assertions, M. Plateau introduces to our notice in the present work a curious law of the duration of impressions. After having corrected certain flagrant errors found in Helmholtz's work, in that part in which the latter refers to Plateau's researches into the subject of the duration of luminous impressions on the retina, he proceeds to the subject of the present communication. Helmholtz, not clearly understanding one of Plateau's experiments, declares that, according to the latter, the correspondence in the angular size of the black and white sectors of a rotating disc does not in any way affect the degree of speed of rotation necessary to effect the disappearance of the twinkling (*papillotage*). What Plateau really stated, and what is substantially true, is that with two discs, the black sectors of which are not equal to the white, the quickness of rotation of the discs necessary to obtain a uniform tint is the same, if the angular size of the white sectors of the one be equal to that of the black sectors of the other, and if the black sectors of the one be equal in size to the white sectors of the other.

The two tints thus obtained are complementary in this sense, that the sum of their brightness is equal to that of the pure white employed.

It is by modifying this experiment that Plateau has been successful in elucidating the following facts :—

Let us suppose a series of discs with black and white sectors, arranged in such a manner that the angular size of the white sectors shall diminish more and more as that of the black increases ; the uniform grey tint of the rotating discs will be deeper and deeper, that is to say, that the impression of white during the rotation will be fractionally less and less than that obtained by looking at a white section in repose ; in other words, the impression obtained will be less and less complete in proportion to the possible maximum obtainable by looking at the white sectors in repose. Therefore, in order to obtain the uniform grey tint, the larger the white sectors the shorter should be the time of passage of the black.

It is evident that the time of passage of a black sector corresponds to the time during which the incomplete impression of the whole has not sensibly diminished.

Modifying these experiments, and interpreting the facts, Plateau arrives at the following conclusions :—

(*a*) Firstly, that a complete impression, whether it be intense or feeble, has never an appreciable period of apparent duration, and therefore that this period exists only for incomplete impressions ; secondly, that its length is in proportion to the incompleteness of the impression, that is to say, more on this side of its maximum.

(*b*) The degree of illumination to which the object which produces the impression is submitted has an influence on the apparent duration, but this influence is slight.

Doubling the time in question, the difference will about equal that between the light of a clear day and the light of the full moon. This slight influence appears also to be indirect.

(To be continued.)

Clinical Records.

LOUTH COUNTY INFIRMARY.

Under the care of HERCULES MACDONNELL, M.B., M.Ch.

Case I.—The following case of organic stricture presented so many points of interest, that it is considered worthy of being recorded.

Owen R., æt. 34, was admitted on the 25th of May, 1877 ; has been a most irregular liver, and given to habitual excess in drink. His appearance defies description, being worn, anxious, haggard, smelling most foully, his clothes being saturated and rotten with urine. His appearance would lead to the belief that he was 50. For the last two years he has been suffering from incontinence of urine. On examination with wax bougies two strictures were discovered, one was situated 2½ inches from the meatus, the second 5½ inches. The patient has been unable to pass a stream of urine for the last fortnight, the bladder relieving itself by constant dribbling. A hot bath was ordered, and 25 drops of tr. opii. Subsequently, an attempt to pass a No. 1 gum elastic catheter was made, but failed.

May 26th.—The dribbling has continued, the bladder is fully 5 inches above the pubis ; no catheter can be passed. The bladder was punctured above the pubis, and the canula left in.

27th.—Slept fairly last night. Urine clear ; passed a wax bougie, which was kept in for one hour.

28th.—Replaced canula, which had become disengaged with a No. 3 gum elastic catheter ; ordered pills, con-

Digitized by Google

taining half a grain of opium and two grains of calomel, every sixth hour.

29th.—Urine contains mucus; is to have an exclusive milk diet.

31st.—Catheter has become choked; cut off the end of a No. 8, and passed it into the bladder over the No. 3.

June 1st.—Blood and mucus in urine; passed a No. 3 wax bougie into the bladder, subsequently attempted, unsuccessfully, to pass a gum elastic catheter; ordered a mixture containing tr. buchu, acid nitric dil. and decoct. Pareira brav., three times daily.

4th.—Less mucus and blood; is to have mixture four times daily; injected bladder with warm milk.

7th.—Urethra more tolerant of wax bougie, but will not allow the smallest catheter through.

16th.—Passed a No. 4 filiform bougie; complaining of pain in abdominal wound.

19th.—Opened a perineal abscess; to have quinine and opium pills.

22nd.—Urine in a small stream followed bougie out; filiform bougie easily passed; to resume nitric acid mixture

24th.—Replaced gum elastic catheter with a Holt's winged catheter; to resume ordinary diet.

July 1st.—Shivering and sickness of stomach last night; replaced winged catheter with a No. 3 gum elastic.

5th.—Has been getting worse; urine cloudy; to return to milk diet.

6th.—Rigors; tongue dry; temp., 103·2.

9th.—Still suffering from pyrexia.

12th.—Passed a No. 2 gum elastic catheter per urethra.

17th.—Passed a No. 5 gum elastic; delirious.

22nd.—Pyrexia has subsided; removed catheter from abdomen (57th day); passed a No. 5 through urethra, to remain until to-morrow.

24th.—Passed a No. 6 Mercier; put a silver pin across abdominal wound.

26th.—Passed a winged catheter into bladder; abdominal wound healed up; to return to diet, and mist. ferri and quiniæ.

29th.—Dilated urethra to No. 12; to get up for first time.

August 4th.—Opened a scrotal abscess.

30th.—Up every day; urethra admits No. 12 silver catheter readily; appetite good; sleeps well.

31st.—Left to-day, perfectly cured: has increased one stone in weight.

(To be continued.)

Department of Lunacy.

NOWELL *v.* WILLIAMS.

This extraordinary action which has been allowed to occupy so much of the valuable time of our law courts terminated at a late hour on Thursday evening, with a verdict for the defendant. It was a difficult thing from the strange nature of the evidence elicited, and which remained uncontradicted throughtout the trial, to arrive at a different conclusion. The whole narrative of this painful case is at the present time before the public, and it is only our intention to briefly allude to it.

It appears that Mr. Williams, the brother-in-law of Dr. Nowell the plaintiff in this action, in consequence of his extraordinary behaviour, decided to protect his sister from his repeated threatened attacks and place him, for his own protection and that of his wife, in an asylum. The delusions under which he suffered were that he was persecuted and watched, and in order to protect himself from these "imaginary" individuals he carried a loaded pistol in his pocket, intending to use it if required. He accused these persecutors of taking undue familiarities with his wife, and alleged that one of them was in bed with his wife and one of his children at the same time. In consequence of his alarming behaviour, in one instance seizing his wife by the throat, and saying that he would do for her, she left her home, and sought the protection of Mr. Williams, her "only living relative." It was consequently found necessary to place him, under lunacy certificates, in Northumberland House in February, 1877, the "order" for admission being signed by the brother of Mrs. Nowell, the defendant in this action, and the lunacy certificates by Dr. Newman and Dr. Sabben at Ramsgate. Upon these documents he was admitted into the asylum. It appears, however, there were certain informalities in the certificates, and the Commissioners in Lunacy visiting the asylum ordered his discharge, but to be re-admitted the same day on the certificates of Dr. Kesteven and Dr. Bucknill. In consequence, however, of receiving various communications from medical men and others as to the incarceration of Dr. Nowell as a lunatic, a special visit was made to Northumberland House by Mr. Phillips and Mr. Cleaton, two of the Commissioners in Lunacy. The result of this visit was a long and exhaustive report in the "patients' book," a copy of which was forwarded to the Commissioners' office and produced in court. The substance was, that they considered Dr. Nowell to be a "dangerous lunatic," and that he was properly detained in the asylum. It subsequently became necessary to apply to the Court of Chancery for a Commission in Lunacy, to place the monetary affairs under the protection of the Court.

The plaintiff, upon receiving notice of this, applied through his solicitor for a special jury to try the case, and in November, 1877, it was heard at Red Lion Square. In order to substantiate his sanity, Dr. Maudsley and Dr. Forbes Winslow were instructed to examine him by Mr. Scott, the solicitor then acting for Dr. Nowell. Dr. Maudsley visited him at the asylum, and Dr. Forbes Winslow on the second day of the Commission at Red Lion Square. Both these gentlemen expressed it as their opinion that he was suffering from a dangerous variety of insanity, and as this was their unbiassed opinion it was deemed inadvisable to call them as witnesses for Dr. Nowell. The result, however, of the Commission before the jury, was to pronounce Dr. Nowell of sound mind, and capable of managing himself and his affairs. In consequence of this decision Dr. Nowell was advised, though we cannot but think most injudiciously, to bring the present action into Court, which is, we learn, only one of many others he contemplates entering upon.

Apart from the testimony of lay witnesses as to his insanity, the leading specialists of the day were called as witnesses, including Dr. Tuke, who visited him as the consulting-physician of Northumberland House; Dr. Bucknill, who signed his certificate; Dr. Maudsley and Dr. Forbes Winslow, who were two independent witnesses; and as Lord Coleridge remarked in his summing-up, approached the case in quite an unbiassed way. Great weight must therefore be given to the evidence of Dr. Maudsley, and Dr. Forbes Winslow, who having been consulted by plaintiff's own solicitor, refused to state that he was of sound mind, but were compelled to attend the trial on a *subpœna*,

Digitized by Google

issued from the defendant's solicitor. The attention of the jury was especially drawn to the fact that much of the evidence placed before them at this trial was not before the jury when the Commission was held in November, 1877, and consequently it would be no insult to the other jury to reverse their decision. The case terminated with a verdict for the defendant, with suggestions made by the jury that medical certificates should be signed on separate forms, and that sufficient trouble was not taken, as a rule, in filling up these documents by those signing. We will refer in detail to a discussion of these points on a future occasion.

It is, indeed, a lamentable spectacle to have accusations made against persons without one tittle of evidence to support them, to have private family affairs dragged into a court of justice, to have the characters of respectable peo- taken away by a person in the condition the plaintiff was in 1877.

Mr. Williams behaved in a thoroughly straightforward and unprejudiced manner under the unhappy circumstances in which he was placed, and if he had not acted promptly in confining Dr. Nowell as a "dangerous lunatic," and protecting his sister from the premeditated and oft-repeated threats of his brother-in-law, his conduct would have been most reprehensible. He however leaves the Court with the strong conviction of everyone who is conversant with the details of the case, that he at least has done his duty—though to fulfil such duty has involved him in great pecuniary losses, and what is more, in great mental anxiety. But not only has he done a private duty, but he has protected the public from the actions of an individual whom, by their verdict, the jury have pronounced as being, at the time of the incarceration, a "dangerous lunatic."

Dr. RADCLIFFE CROCKER on

A CASE OF CONGENITAL SEBACEOUS DISEASE OF THE HEAD AND NECK.

This was a case in which a male infant, æt. 6 weeks when brought to University College Hospital, was born with patches on the skin of the occiput, left side of the head, both cheeks, the front of the neck, this last joining by processes those on the cheeks. Small patches existed on the left alæ nasi and inner angle of left orbit, and in the vicinity of the large patches. The patches varied much in size, the largest on the occiput measusing 9¾ by 2¾ inches in its greatest dimensions, the smallest about ¼ in. in diameter. They were irregular in shape, narrow processes branched off them, and showed signs of being formed by the coalescence of several into one by small sulci, sometimes with a slightly raised edge at the borders of the sulci. The whole patch was slightly raised, the edge more than the rest, and these edges consisted of comedones, with their usual black tops. These were also seen—but not so close together—on the borders of some of the dividing sulci, and occasionally one or two sometimes suppurating on the surface. The general surface at first sight appeared smooth, but on looking at it closely it was seen to be finely granular, a pale yellowish red, but varying in tint, growing redder when the child cried, and paler when exposed o cold. The patches on the scalp were quite hairless; they had not increased in size since birth, and the mother thought they were decidedly less prominent, but not smaller. The child was well nourished, the skin was healthy, except for these patches, and had not had any other kind of eruption. There were no snuffles when first brought to the hospital, but it caught cold three days after, and then snuffled slightly. There was no evidence of syphilis besides this, either in the infant or his sister, three years old, the last being in good health. The mother had not been ill, or even ailing, since her marriage, five years before, and the father had never had a day's illness for the seven years she had known him. The presence of comedones on the edge, and occasionally on the surface, suppurating like ordinary acne, point to its being of sebaceous origin; and though the surface might be of a different nature, the individual granules have much the appearance of milium on a small scale, with a yellowish tint. The case appears to be unique.

Dr. DUCKWORTH said he had never seen a case in any way resembling the one described. He had examined the case with Mr. Hutchinson, and had at the time concluded that it might have a syphilitic origin. This opinion, however, could not now be maintained. He thought a committee should be appointed to make an accurate investigation into the case.

The PRESIDENT agreed with Dr. Duckworth that the case was a unique one, and was fully deserving of being made the subject of investigation by a committee. He proposed this should consist of Dr. Duckworth, Mr. Hutchinson, Dr. Robert Liveing, and Dr. Crocker.

Dr. W. SPENCER WATSON on

A CASE OF OPHTHALMITIS (DOUBLE) TREATED BY DUBOISIN AND MERCURY.

Both eyes of a woman, æt. 37, were seized, one a few days after the other, with acute ophthalmitis, with severe pain, tenderness, and inflammatory redness, but no purulent discharge from the conjunctival surfaces. The sight was so nearly destroyed that the patient had to be led into the waiting-room. Duboisin drops were used freely and frequently after the failure of atropine, and at the same time mercury was administered by inunction and by the mouth. The gums became tender in a few days, and simultaneously an improvement took place in the condition of the eyes, the sight gradually improving in both, and so much so that in the eye last and less severely affected good-sized type was distinguishable, and she could do needle-work at the end of a month's treatment. The Duboisin drops produced full dilatation of the pupils, and though used at intervals of only two hours for some days, no toxic effects were observed, such as have been noticed by other surgeons. The highly congested state of the conjunctival and ocular vessels may have been an impediment to the rapid absorption of the drug, and the usual constitutional symptoms may have been prevented from this cause.

Dr. THEODORE WILLIAMS on

A CASE OF PERFORATING WOUND OF THE LUNG, ENDING IN RECOVERY.

(Reported by Surgeon-Major ALCOCK.)

On May 8th, 1878, Trooper G of the Frontier Light Horse, æt. 30, during the Transkei war in South Africa, was struck through the chest by a rifle bullet in a close attack on a Kaffir position. He was carried to the Field Hospital, two and a-half miles distant, and arrived in a very exhausted state. The bullet had entered through the fourth intercostal space on the right side internal to the nipple, and had escaped through the ninth rib, which it fractured about one and a-half inches from the spinal column. Air, blood, and mucus escaped freely from both wounds, and the patient expectorated a considerable amount of blood. The wounds were treated by lint soaked in carbolic acid, covered with loose freshly-picked oakum, held on by a bandage, so as to act both as a respirator and disinfectant to the wounds. The dressings were changed night and morning, and the parts carefully washed with a solution of Condy's fluid. Chloral and morphia were given from time to time. During the first two days the patient was distressed by the frequency of the cough, and the temperature was 100·2° F. But afterwards he rapidly improved, the discharge being copious from both wounds, and except on one occasion, when owing to the bandage being tightened, the secretion was pent up, thereby causing distress and slight rise of temperature, no drawbacks occurred, and the patient was able to be out of doors one month after the injury with both wounds

Digitized by Google

healed, and free from cough. The lung was thickened along the track of the bullet, and there was some signs of consolidation in the lower lobe.

Mr. BRYANT remarked that the successful progress of the case prevented the possibility of many points arising for consideration about it. But he would suggest that it showed two things—first, the benefit of non-interference in chest injuries, as opposed to the older modes of treatment; and secondly, the advantages following the existence of a free outlet for purulent discharges. This latter was the main lesson to be learned from the case, as presented to them.

Dr. S. J. POLLOCK thought the case proved that fatal consequences are by no means to be anticipated from punctured wound into the lung. The time, moreover, is rapidly approaching in which the advantages of free openings to secure an efficient drainage of wounds will be fully recognised, and in empyema the necessity of adopting such means towards healing are becoming daily apparent. This, and like cases, tend to prove that even serious injuries to the lung can be safely recovered, and that artificial drainage wounds may even be made with every prospect of a successful result.

Dr. WILLIAMS briefly replied on behalf of the author, drawing attention again to the conditions under which the case had progressed.

Mr. A. T. NORTON on

SYPHILIS—REMOVAL OF FRONTAL PORTION OF FRONTAL BONE, ROOF OF BOTH ORBITS, ETHMOID BONE, PARTS OF BOTH SUPERIOR MAXILLARY BONES, VOMER AND PALATE, LEFT WING OF SPHENOID BONE, AND THE LEFT EYE—COMPLETE RESTORATION TO HEALTH.

The subject of the paper contracted syphilis in June, 1866. He was of a strumous constitution, having suffered previously from strumous psoriasis, and since acquiring syphilis, from strumous arthritis of the left knee-joint, followed by anchylosis. The chancre healed in about five weeks, and was followed by an eruption of small vesicles and sores every two or three months for more than a year. The glands of the groin were swelled, but the patient never suffered from sore throat, nor from any cutaneous eruption whatever. His habits were intemperate, and about a year after the chancre, syphilitic ulceration attacked the matrix of several toe-nails. About Christmas, 1873, he had a severe attack of syphilitic laryngitis, and in 1875, a suppurative and foul discharge flowed from both nostrils, followed by necrosis of the bones of the nose, and of the left palate and superior maxilla. From time to time pieces of bone were removed by various surgeons, and in June, 1876, he came under Mr. Norton's care. At that time, the ethmoid bone was necrosing, and a suppurating node occupied nearly all the frontal portion of the frontal bone. All stimulants, of which he had previously been taking a large quantity, were prohibited, and the iodide of potassium treatment stopped. Quinine and iron and opium, with milk and simple diet, were advised, and a point was made of not allowing the patient to undergo any change of temperature. In October, 1876, sight was destroyed in the left eye, and the left half of the sphenoid bone was separating: this mass of bone was ultimately removed through the nose; a large part of the left superior maxilla having previously been taken away allowing space for the operation. It was now evident that the frontal and ethmoid bones would be destroyed, and the suppuration was exhausting. The patient was, therefore, never allowed to leave the house, but kept in an unchanging temperature of 62°. On July 4th, 1878, the bones were in a fit state for removal. An incision was made perpendicularly upwards from the nose to the sagittal suture, and from each end of this central incision lateral incisions were carried outwards; in the upper part along the coronal suture, and in the lower part along the orbital ridges. The flaps thus formed were turned outwards to expose the whole of the frontal bone. Gentle traction and manipulation brought away the frontal portion of the frontal as far outwards as the temporal ridges, the cribriform portion of the ethmoid bone and the roofs of both orbits. The left eye being inflamed and suppurating, and its sight gone, was also removed. Granulations rapidly sprang up, and the discharge was no longer fœtid; some bone was re-forming over a part of the forehead. Mr. Norton considered it astonishing that health could have been maintained under the prolonged and exhausting suppuration which occurred during the separation of the extraordinary quantity of necrosed bone, especially as much of the pus, which was horribly foul, found its way into the stomach through the nose. Further, it was remarkable that the brain should be in no way affected, notwithstanding that not less than its entire anterior third was supported and covered in by cicatricial tissue only. As far as treatment was concerned, the drugs usually administered in syphilis were avoided, the object being to maintain a desire for food, and—looking upon a patient suffering from syphilis as one predisposed in the extreme to inflammation—to avoid all changes of temperature, and so withdraw the patient from the influence of the most common exciting cause of inflammation.

Mr. BRYANT thought it would be well to postpone the discussion on this case until the portions of bone could be produced, the point of interest in connection with it centering on the formation of new osseous plates. By examination of the patient (who was present in the room), he could discover only one place where it was not re-formed, and the extreme rarity of any such restoration after removal of syphilitic caries rendered it important to have the complete details before them.

By unanimous consent the discussion was adjourned as proposed.

Dr. GOODHART on

A CASE OF UNUSUAL DEVELOPMENT OF KELOID IN SMALL-POX SCARS.

The patient is sixteen years of age. He had never been vaccinated, and in March last he had small-pox, and the disease so severe, that bed-sores formed on his shoulders, elbows, hips, and back. He was in bed four months, and during that time the present disease came on. Since that time it has been slowly decreasing. The face and neck, shoulders, and upper extremities, and the legs, are the parts where the disease is most abundant. On the thighs it attacks the seat of old bed-sores, and over each great trochanter, and over the sacrum there is a similar keloid scar. The appearances in the various parts vary somewhat. Thus, on the face, where perhaps the greatest exuberance of growth is shown, there are large flattened masses of solid growth, occupying chiefly the inferior maxillary region, though by no means confined to it. The skin of the face is more or less trabeculated all over by an irregular growth of thickened scar bands, giving the features a rather elephantine expression. The cuticle in these parts is red, traversed into small capillary vessels, smooth and shiny. The sacral and trochanteric regions show similar masses of keloid, but in these parts the entire scar is not so universally affected, and the skin is much deeper in colour, being a dark purplish brown, like a recently-healed wound. From the ill-defined outline of the disease in these parts, and the depth of the pigmentation, I believe that the disease is disappearing, and the patient himself and his father say that they are less in size. On the arms and forearms, except over each olecranon, where there has been a bed-sore, the keloid lumps are mostly circular and discrete, though numerous, and the same may be said of the legs. In both arms and legs they are mostly about half-an-inch in diameter, a deep livid brown in colour, smooth on their surface, and indurated like an infiltrated scar. They are mostly present on the outer aspect of the arm and forearm; on the back of the hand, and on the shin. Some of the lumps in both legs and forearms are certainly disappearing, leaving a soft, slimy, slightly depressed, pigmented cicatrix. The unaffected skin, that mostly is on the lower part of the trunk, is thickly covered with the pits of small-pox vesicles, but these as yet show no alteration like keloid, though they are distinctly raised. There is no history of any tumours in the family so far as the patient himself can say, and his father. I have brought the case to the Society for three reasons, first, because it seems to me to be a very unusual extent of development of keloid, and in reference to its occurrence in the cicatrices of small-pox, I should say that it seems to me possible that in the small-pox scar there may be some unusual facilities afforded to such a growth as this, because I have observed keloid not unfrequently take place in vaccination scars. Secondly, I wish to hear from any member who may have seen any similar case, whether I am justified in holding out, as I am doing, a hope to the patient that the keloid will ultimately all disappear; and further I wish to show the case at this early stage, that if anything unusual happens I may exhibit the patient again in some months time.

Mr. SQUIRE thought that a marked distinction can be drawn between the keloid of syphilitic scars and that of non-syphilitic origin.

Mr. CHRISTOPHER HEATH considered this case to resemble

Digitized by Google

in character the ordinary keloid, but unlike the variety known as Addison's. He had not known a keloid developed after a burn to disappear.

Mr. SQUIRE explained that he agreed to call the instance under discussion one of ordinary keloid; but it differs from the syphilitic variety. The spontaneous keloid, he continued, follows non-syphilitic scars, and may disappear as it arises, *i.e.*, spontaneously.

Mr. GANT drew attention to the fact that one of the most interesting features of the case is the marked symmetry of the growth; patches on the jaw and shoulders being markedly so. He thought the development of the keloid might be intimately dependent on the condition of the blood, and he further showed how the influence thus exerted can be traced in numerous instances.

Mr. MORRANT BAKER said he had, then, in the outer room, a patient exhibiting Addison's keloid, and it would be interesting to compare the two cases. He could not follow the distinction attempted to be set up by Mr. Squire.

Mr. SQUIRE had observed a marked difference in the plates depicting the varieties of keloid in Alibert's works, and it was on this he founded his belief, together with the result of his own personal observation, which enabled him to distinguish an essential difference between syphilitic and ordinary keloid.

Dr. DUCKWORTH pointed out that Mr. Hutchinson had declared keloid to follow on the formation of scars, almost invariably. Alibert's keloid, however, is frequently a sequela of irritant applications, and its common occurrence over the sternum could be attributed to the blistering stimulation of the præcordial region. In a case under his own care this had taken place, Alibert's keloid developing and continuing slowly after. In the case under discussion the present soft vascular masses would, he thought, in time become firmer and more scar-like. He did not know any distinctive signs whereby syphilitic keloid might be separated from the ordinary form.

DR. LIVEING observed that Hebra mentions one or two kinds of keloid in acne scars. He imagined spontaneous keloid might originate in small scars.

Mr. MALCOLM MORRIS mentioned a case in which keloid, eventually almost entirely disappearing, followed after operation. He was struck also by the remarkable symmetry exhibited in Dr. Goodhart's patient, and thought it notable that the symmetrical appearances should be found where keloid developed on the loci of bed-sores independently of scars. He was familiar with Alibert's plates, and considered them identical with representations of ordinary keloids.

Dr. CROCKER had recently treated a case in which keloid developed on acne scars. The spots had never disappeared in his experience. He thought there might be more than one *phase* of keloid, and suggested that Dr. Goodhart should remove one of the spots from his patient and submit it to examination.

The PRESIDENT proposed the appointment of a committee to inquire into and investigate this case, and draw up a report dealing with the differences that may exist between the varieties of keloid. The suggestion having been adopted,

Mr. GOLDING BIRD detailed a case in which keloid succeeded to a boil, and continuing to grow for a year, was raised as much as one-third of an inch from the shoulder, and as large as a split hazel-nut. At the present time, three years after, the skin presents only a white scar. He could vouch for the absolute accuracy of his description, being, he said, himself the subject of it.

Dr. CALCOTT FOX had seen keloid tumours distributed over the whole body, as many as twenty or thirty. They were large and pedunculated, some the size of a largish mushroom. They had been under observation fifteen years, had been removed, and returned again.

IN the principal foreign cities the rates of mortality according to the most recent weekly returns were—in Calcutta 22, Bombay 34, Madras 38; Paris 24; Geneva 17; Brussels 20; Amsterdam 20, Rotterdam 20; The Hague 27; Copenhagen 30; Stockholm 20; Christiania 15; St. Petersburgh 32; Berlin 26, Hamburg 25, Dresden 20, Breslau 25, Munich 42; Vienna 24; Buda-Pesth 31; Naples 25; Alexandria 40; and New York 23 per 1,000 of the populations.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 19, 1879.

RATIONAL CHEAP DIETARIES.—I.

AT the present time the question of our food is attracting great, almost universal, attention. The pressure of narrowed means is felt alike by the peer, who finds it necessary to forego his rents, or to return a large percentage, and the peasant, who toils for a reduced day's wages. One and all feel that during a period of great national prosperity, when, indeed, we had gone on "by leaps and bounds," our living had become extravagant, and our prodigality in our expenditure on food almost disgraceful Our methods of preparing our food are wasteful in th extreme. Costly solid joints, rendered more extravagant by the waste in their cooking, were commonly seen on the artisan's table. Then follows cold meat, and after that, that British abomination, a hash made with cooked meat; if there existed thrift enough to attempt the last. Such cooking involved the smallest amount of culinary knowledge, and the least trouble to the housewife. And it is the mental attitude of the British, and especially the English housewife, which furnishes the greatest difficulty to be encountered in the attempt to institute something better. She is satisfied with her cookery knowledge; she knows as much, and secretly believes rather more, than her housewife neighbours. What she does not know is not worth knowing; that is her firm conviction. She has studied cookery books, but apparently has not been impressed by them; nor is this so much a matter of surp for the cook, when he or she wields the pen, seems

Digitized by Google

to have a quiet dinner party in their eye, rather than a mere family dinner. It is in the preparation of simple dishes that the housewife needs instruction so much. The first thing to be impressed upon her consciousness is this: No household ever should have put upon the table a hash made with meat previously cooked, nor a "Saturday pie." The food should be so prepared that this can be avoided. If a joint is insisted upon, it should be of such size that it can only appear twice; and the bones then be ready for the soup kettle. Medical men all know how indigestible is meat cooked a second time, and in a different manner. Even when a dish has to be "hotted" it usually suffers from the process. Such, then, is the first article in our belief, viz., that just enough should be cooked to admit of its being eaten when fresh.

The next point is that strength, as it is termed, is not solely to be found in solid lean meat only. This is a very common delusion with the working classes. They must have meat to give them strength! Yet we rarely had hardier, more powerful enemies to contend with in battle than the Sikhs of the North West of India, whose religion forbids their eating meat. These "pulse-eaters" are fine stalwart men; and so are the Zulus, who live on milk and maize. A great deal of the best agricultural work of the world is performed by men who do not eat meat—in its ordinary sense—the Scotchman, ploughman, or shepherd, who lives on oatmeal porridge; the out-Western American, who lives on "hog and hominy," are cases in point. On this subject, perhaps, the medical man can give much help in the form of counsel to housewives, and we will put the matter as simply as possible. We require for the formation of the tissues of the body, albuminoids, that is, materials containing nitrogen, of which egg albumen, lean meat, the flesh of animals, and caseine, or the pulses, are the commonest forms. Fat is required both for healthy tissue formation and for body-fuel: this can be taken as fat, oil, or butter, or manufactured within the system from saccharine, or starchy matters, taken as food. Such, then, are the tissue requirements. But the meat-eater will naturally ask the question, "How much meat do I require for my tissue-needs?" How much, or rather how little these tissues require, physiologists have not yet told us: but it is much less than even most medical men suppose. The hypothesis that all the urea and uric acid passed in the urine have once been tissue, is now exploded. A small portion of our albuminoids only ever are converted into tissue. Possibly not much ever reach the liquor sanguinis; the great bulk is burnt up in the liver, and more or less perfectly oxidised. Of what avail, then, is the superabundance we crave after, and which the artisan calls "strength?" Liebig, long ago, pointed out the contrast betwixt the carnivorous and herbivorous animals,—the meat-eating man and the vegetarian. He observed the sense of energy given by a meat dietary in man; the capacity to manifest energy quickly possessed by the carnivora. Then came the experiments of Parkes, as to the effect of a non-nitrogenous dietary on the blood pressure, lowering it markedly. Side-by-side with these observations lies the evidence furnished by the sphygmograph, as to the rise of arterial tension when the blood is charged with nitrogenised waste; where Mahomed has done such good work. Then come the observations of George Johnson, Grainger Stewart, Dickenson, and Milner Fothergill, on the tense pulse of lithiasis, and the capacity evidenced by stalwart gouty men. The high blood-pressure in the arteries produced by a waste-laden blood, charged with explosive nitrogenised materials, causes the vessels of the encephalon to be well filled with blood, which vascularity of the brain, in its turn, confers the subjective sensations of energy. This pleasant subjective condition is one which the enterprising Anglo-Saxon loves, and for which he will pay a long price in dear butcher's meat. But in the pulse tribe are to be found the most highly nitrogenised bodies known to us as foods. In the lentil, the pea, either split or the "blue-boiler" (the dried green pea), and in the haricot bean, do we have highly nitrogenised foods, at a price far below that of meat. In the dried pulses, ground into flour, or cooked whole, do we find our cheapest albuminoids. Combined with animal fat they form compounds of a high food value. Such combinations give a large quantity of albuminoids along with fat, the most concentrated form of hydro-carbon, and, consequently, their food value is very great. The Erbwurst of the German army of 1870 consisted of pea-flour and pig-fat, the richest and most economical food that has yet been devised. Small in bulk, this really concentrated food was readily carried about: its weight did not task the commissariat; it kept well, another great advantage; while it was readily converted into a palatable soup. Most authorities agree this sausage had much to do with the result of the war of 1870-1. It is not then, indispensable to have lean meat with vegetables, an expensive, if palatable combination. We can have animal fat combined with vegetable albuminoids; cheaper far, if not quite so appetising—though that may be a matter of opinion. The artisan need not be apprehensive that his strength will fail him on such a dietary. A further point about lentils and pulses is this: from personal experience and clinical observation we are strongly inclined to hold that vegetable albuminoids are more easily digested, and produce less "gout poison," less lithic acid and lithates, than do animal albuminoids, and therefore are really to be preferred. The charge that vegetables produce flatulence can be met by the statement that they lack meat-salts, and, as ordinarily cooked, are "windy." But then this drawback can be met by condiments, and especially pepper, used by many so sparingly. Yet vegetables not only require condiment, but they carry them well, and are much improved thereby.

A third point in a rational dietary is that it shall contain matters which are called "anti-scorbutic," without which scurvy and skin diseases will show themselves. Before the days of the potatoe, in winter "land scurvy" was far from unknown. "Dry" and "wet scurvy" were the brief and crude divisions into which skin affections were split.

Certain vegetables, then, have a high value; not for their hydro-carbons, or their albuminoids, but from their anti-scorbutic properties. Such are the cabbage, spinach, Brussels sprouts, others of the crucifera, the onion, asparagus, seakale, &c. The carrot, the turnip, and the beetroot also contain a distinct proportion of sugar. The potatoe is fairly rich in starch. All the fruits, as the apple, the pear, orange, lemon, tamarind, the grape, and gooseberry, contain vegetable acids and salts, which make them agree.

Digitized by Google

able additions to our dietaries. From want of vegetable food the Icelanders are notoriously subject to scurvy in winter; and many diabetics, too rigidly dieted, become ill with purpuric patches, allied to scurvy. The pulses and the cereals, high as is their food value in other respects, do not possess anti-scorbutic properties, and therefore, for health, other articles of food must be eaten with them.

THE EXPURGATION OF THE DENTAL REGISTER.

The British Dental Association has taken in hand the appalling task of clearing the "Dentists' Register" of the names of those who are not dentists at all, and who have got themselves therein recorded upon false pretences, and would seem to be entering upon its labours with an earnestness which inspires hope of their ultimate success.

Our readers will recall to mind the circumstances under which these persons obtained official recognition as dentists. They were entitled to be so recognised if they made a declaration that they "are *bona fide* in the practice of dentistry either (*a*) separately, or (*b*) in conjunction with pharmacy." The Act simply required a candidate for registration to make this declaration respecting himself, but did not authorise the Medical Council or any one else to verify the truth of that declaration. The candidate, therefore, went on the Register *ipso facto*, but was liable to be called upon to swear to the truth of it, and to have his name removed (under Sec. 13) if the "entry has been incorrectly or fraudulently made."

As any person could obtain recognition as a dentist if he could honestly say that he was *bona fide* in the practice of dentistry, no matter what his idea might be of the meaning of that phrase, of course a multitude of pretenders to the dental art did so obtain recognition, and it is to the expulsion of these persons from the ranks of the profession that the British Dental Association is now applying itself. It has commenced the war by obtaining the opinion of eminent counsel on the subject, who advises them as follows:—

1. (*a*). A person who, being at the passing of the Act engaged in the practice of dentistry, and also in some business not mentioned in the Act, declared himself to have been engaged in the practice of dentistry separately, is liable to have his name erased from the "Register."

(*b*). A person who declared himself to be engaged in the practice of dentistry in conjunction with pharmacy, but whose name was not in the "Chemists' and Druggists' Register," is liable to have his name erased from the "Register."

The gist of this opinion is that a registree may be struck out (*a*) if he has obtained registration as a practitioner "separately" when in fact he was engaged in some other business. (*b*) If he has been registered as a pharmaceutic dentist, he not being a legally recognised pharmaceutist, *i.e.*, not named in the "Chemists' and Druggists' Register." These are disqualifications to which it is quite easy to apply a test, but the British Dental Association will be obliged to apply that test themselves, and to supply the proof, cut and dry, to the General Medical Council, for that body will certainly refuse to initiate any inquiries having for their object the removal of a registered name.

Respecting the class of persons who are registered chemists and druggists, or who are nominally in the separate practice of dentistry, a much more difficult question arises. Here it will be necessary to discuss the question, What constitutes the *bona fide* practice of dentistry? and the legal question arises, whether, under the terms of the Act, a name can be removed as long as the declaration was made honestly, even if the registree's idea of *bona fide* practice was plainly erroneous. On this point counsel advises the British Dental Association as follows:—

2. (*a*). I think that an assistant in a chemist's shop, where teeth were occasionally extracted, even if registered in the "Chemists' and Druggists' Register," cannot be considered as engaged in the *bona fide* practice of dentistry, so as to entitle him to remain on the "Dentists' Register."

(*b*). I think that the occasional performance of one class of dental operation, such as the extraction of teeth, does not constitute *bona fide* practice of dentistry.

(*c*). The *bona fides* applies equally and separately to the practice of pharmacy, and an assistant in a chemist's shop, not registered in the "Chemists' and Druggists' Register," cannot be regarded as in the *bona fide* practice of pharmacy within the meaning of the Act.

(*d*). Whether a dentist's assistant can be considered as in *bona fide* practice, so as to entitle him to be on the "Register," depends on the amount and nature of the assistance furnished by him to the dentist. The assistance must be such as to require the possession of *some* dental skill and knowledge.

How far the opinion thus given can be acted upon we must leave to experience, and to the good sense of the General Medical Council. That body may be called upon to decide whether the perfunctory practice of tooth-pulling by a druggist can be regarded as "*bonâ fide* practice," and we will hope that it may consider that unless a druggist was avowedly engaged in dentistry, proclaimed as a dentist previous to the passing of the Act, and prepared to undertake *all* the work of a dentist, he could not be honestly said to be registrable. The British Dental Association is no doubt unwilling to deal harshly with any person who has obtained recognition as a dentist under a misapprehension, and would, of course, be anxious that any such person should voluntarily remove his name from the Register rather than incur its compulsory removal. As to his competency so to withdraw from his false position, counsel advises:—

3. The name of a person can be removed from the "Register" at his own request, without any reason being given by him. Of course the Registrar would require a *written* request, signed by the person making it. The restoration of a name once removed is a matter for the discretion of the General Council (S. 14), after the facts of the case have been ascertained by the standing Committee appointed under S. 15. I do not think that a person desiring to have his name removed could be legally required to make a declaration relinquishing all claim to restoration on the ground of *bona fide* practice before the passing of the Act.

4. The witness to the declaration in the Schedule to the Dentists Act is a witness merely to the signature of the declarer; but if he signed, knowing the declaration to be false or fraudulent, he would be liable to be proceeded against under S. 35.

We read with much satisfaction these decisions of a legal authority whose rank entitles his opinions to much credit. We confess we hardly hoped for so promising a prospect of the expurgation of the Dental Register, and with such advice before them we are satisfied that the British Dental Association will proceed energetically with the work they have in hand.

The Executive Committee of the General Medical Council have been summoned to meet on Friday, the 28th inst.

Notes on Current Topics.

Modern Surgery.

At the recent Congress of German Surgeons in Berlin, Professor Langenbeck stated that he had performed the operation of extirpation of the pharynx three times, and that he considered the operation justifiable, although all his cases were unsuccessful. The following are the steps of the operation :—

First of all, tracheotomy must be performed, and the canula of Trendelenberg introduced ; then an incision is carried from the body of the lower jaw, midway between the symphysis and the angle toward the greater cornu of the hyoid bone, and thence along the anterior border of the sterno-mastoid as far as the upper extremity of the tracheotomy incision. Next, the sub-maxillary gland must be removed, the lingual artery tied, the stylo-hyoid and digastric muscles detached from the hyoid bone ; the pharynx is then laid bare and can be dissected out, the larynx meanwhile being drawn to the opposite side. The principal dangers to be apprehended are peri-œsophageal phlegmon extending into the mediastinum, and pneumonia from the introduction of foreign bodies into the air passages.

At the same Congress Professor Billroth stated that six months previously he had removed from a women, æt. 42, the pharynx, the cervical portion of the œsophagus, the larynx, a part of the trachea, and all the thyroid gland, for a cancer of the pharynx involving the posterior portion of the larynx. He first performed a preventive tracheotomy, and nine days later proceeded to operate, after introducing the canula tampon of Trendelenberg. The incision was made along the anterior border of the sterno-mastoid. In the course of the operation Professor Billroth found that the tumour extended much further than had been supposed, and as he advanced step by step he found himself compelled to remove successively all of the larynx except the epiglottis, the upper rings of the trachea, a large portion of the pharynx, the œsophagus as far as the sternum, and the whole of the thyroid body. An elastic tube was placed in the œsophagus for the introduction of aliment. During the first four weeks the patient did well, the wound gradually contracting, and the elastic tube was then removed in the hope that the pharynx would unite with the lower portion of the œsophagus, and form a permanent canal for the passage of food. After the removal of the tube, however, deglutition was accompanied by suffocative attacks and vomiting, and the canal contracted, rendering the passage of bougies necessary. In the sixth week a false passage was made in the peri-œsophageal tissue. Pericarditis and death followed.

Kolaczeh, of Breslau, removed a cancer of the posterior wall of the pharynx by a supra-hyoidean pharyngotomy, eight weeks before the Congress met. The patient was still living at the date of the report, and was nourished through a tube placed in the œsophageal fistula. Kœnig, of Göttingen, and Gussenbauer, of Prague, have also removed cancers of the pharynx, and, like Langenbeck, lost their patients from pneumonia, due to the introduction of food into the lungs. To avoid this danger Thiersch has proposed the preliminary establishment of a gastric fistula.

A Double Diagnosis.

An amusing story is told, in the November number of of *Le Praticien*, of a distinguished *savant* at the dinner of the Anthropological Society, Paris. It was not delivered publicly, but whispered in the ear. We have heard a similar tale ascribed to some one else. I visited, said the narrator, a young man aged 15, who without any apparent cause, was getting weaker from day to day. Suspecting albuminuria or diabetes, I asked for the urine of my young client, for examination. What was my surprise, to find in it a quantity of kiesteine. Assuredly this was not the urine of my patient. On my next visit, in presence of the family, I said you are trying to humbug me. I asked for the urine of this patient, and you have sent me that of a pregnant woman. Scarcely had I pronounced these words, when two persons fainted ; the young man and the *bonne* who had opened the door.

She cried out, "Ah ! M. Ernest, you have done for me." Light was thrown at once on my mind.

The maid knew why the young man had fainted. She had sent me her own urine, so that unconsciously, I had made a double diagnosis. There is another story of the same kind, though in verse, which is untranslatable.

The Morgue.

In accordance with the vote passed by the French Government, some important works are about to be executed at the Morgue, under the direction of Dr. Brouardel. All the necessary arrangements for teaching legal medicine will be secured—viz., a hall for autopsies, laboratories, a library, apparatus for the preservation of bodies, &c. A Commission has been appointed, consisting of Delpech, Bourneville, Brouardel, and Bonnet, to select the most scientific and, at the same time, most economic apparatus for the preservation of the bodies.

New Remedies.

Our American cousins are continually introducing new remedies, and we have fluid extracts, in the market, of coto bark, cascara sagrada, folia carobæ, rhus aromatica, damiana, boldo, berberis aquifolium, black haw, grindelia robusta, grindelia squarrosa, kaki, cercis Canadensis.

The surgery, of the practitioners of the future, will have to be as large as St. Paul's Cathedral, if new remedies are produced at the same rate we have had them of late years.

Death of the Father of Cremation.

Dr. Julius T. Lemoyne, the Father of Cremation in America, is dead. He was a retired physician, who had amassed a fortune, and during the past ten years he devoted himself to cremation. Of French descent, he was born in America in 1797. He graduated at Washington University in 1815, and at Philadelphia in 1870. Half a century ago he was Abolition candidate for Governor of Pennsylvania, and later was candidate for Vice-President, on the ticket with Gerrit Smith. He lived at Washington,

Digitized by Google

where his cremation furnace was built. This furnace was the result of much study, and was proved to be a success, when three years ago Baron de Palm was cremated in it. "Hoist by his own petard," Dr. Lemoyne has been "cremated in his own furnace, to the satisfaction of his friends;" so say American papers.

Illegal Certificates.

THE Medical Defence Association have pursued a very proper course in prosecuting Mr. Johnson, a registered practitioner, of South Kensington, for being guilty of a practice that is not uncommon. This gentleman had appended his signature to the certificate of death of a child, which he had never even seen. By the declaration of the certificate he had, of course, been in direct personal attendance on the patient to whom it referred; and the natural deduction from a comparison of the two statements—viz., that of the certificate, and that of the child's mother, to the effect that Dr. Johnson had never seen her infant—is unavoidable. It is impossible to regard the fine imposed —£5, or with the costs, £5 5s.—as in any way too severe a penalty for the commission of the offence. The explanation offered, that the defendant's assistant was acting as his representative, though the usual one, is not sufficient, particularly since, being an unqualified man, he was legally debarred from certifying the cause of death. It is quite likely that this case is only one out of a vast number that might be made the subjects of the Association's attention; and while commending their activity on this occasion, we hope they may be moved to undertake others; to the end that an abuse so calculated to produce mischievous confusion may be effectually crushed.

Medical Men on the Council of the Royal Society.

AT the anniversary meeting of the Royal Society on December 1st, the officers for the ensuing year will be elected. Among the proposed new Council there occur the names of Mr. John Simon, C.B., F.R.C.S., Sir James Paget, Mr. John Whitaker Hulke, F.R.C.S., and Dr. Wm. Odling.

Opiates.

TWO cases of fatal consequences attending the use of opiates occurred in the past week—one through chloral (*again!*), the verdict recording an *over-dose* inadvertently taken; the other through morphia regularly prescribed, one grain to be taken in two doses. The form in which the drug was administered is not stated. We shall return to this question in our next number.

The Americans on Dr. Richardson.

THE inventor of Salunacy apparently excites the keen interest of our Transatlantic neighbours, and induces them to enter with peculiar relish on a consideration of his weaknesses and peculiarities. On the authority of the *Louisville Medical News* the distinguished hygienic speculator's pet amusement is the amputation of female breasts, with a pair of scissors having jagged edges. He operates by aid of the ether spray as an analgesic agent, and dresses the wound with styptic colloid. The arm is then bound down, the patient is forbidden the bed, but may ride and walk as much as she pleases, eating and drinking as seems to her good. The success attending the treatment, we are further assured, is complete and invariable, while the information is added, that Dr. Richardson ridicules the germ theory, and considers carbolic acid "a bad-smelling sham."

Galvani's Monument.

THE English are far behind Continental people in willingness to erect national memorials to dead and gone scientific worthies. The Bolognese have just illustrated the truth of this by erecting in one of their principal streets a monument representing Galvani in the act of performing the experiment that was the first step in the history of galvanism, and the beginning of a discovery that is but now being introduced to its proper place as the physician's assistant. The anti-vivisectors, however, must henceforth avoid Bologna until such time as the destroying hand shall have obliterated the marble testimony afforded by the statue against the pet invention of their unenlightened intelligences. For the great physicist is chiselled in the act of applying two slips of metal to the lumbar nerve of a vivisected frog, thereby illustrating one of the great advances in natural knowledge made through the assistance of vivisection. Will Mr. Jesse and his band deny *this*, we wonder?

Lectures at the Society of Arts.

AMONG the papers to be read at the next session of the Society of Arts, commencing Nov. 19, are the following:—"Suggestions for Dealing with the Sewage of London," by Major-General H. Y. D. Scott, C.B., F.R.S.; "Domestic Poisons," by Mr. Henry Carr. The first course of "Cantor" lectures will be delivered by Dr. Charles Graham, the University College Professor of Technological Chemistry, the subject selected being "The Chemistry of Bread and Bread-making."

Squirting.

A NEW abomination to plague the wayfarer has been recently introduced in the streets, and to so great an extent has it progressed that on festal days the nuisance has been intolerable. It consists of a small metal, or stiff paper-bag, filled with some fluid, which, by pressure on the bag, is squirted in a thin stream on the object of the possessor's attention. When the contents are simply water, or even perfume, they may be tolerable; but when for the harmless fluids, disgusting compounds are substituted, the case at once assumes another colour. During a late holiday the extent to which these infernal machines was employed in the thoroughfares was unbearable; and in more than one instance offensive solutions, urine, &c., were squirted into the faces of passengers. A feeble attempt to put a stop to the nuisance has been made by one or two magistrates; but until the annoyance is met by a much more effectual corrective than the imposition of a nominal half-crown fine, we may expect to see it, and smell it, in flourishing continuance. Serious evil may attend the practice unless it be at once permanently checked.

Overcrowding at the London Cliniques.

We understand that in consequence of attention being drawn by us to the subject of overcrowding at the *cliniques* of the London Hospital, chiefly by those who have only entered for special subjects, to the great detriment of perpetual students, the authorities are debating the best means for lessening or removing the evil altogether. Unfortunately, the grievance is not confined to the London Hospital, although it is more pronounced there, on account of the large number of "special" entries; but the commendable promptitude of the governing body in the matter will, doubtless, not be without its effect upon other institutions, which we shall not fail to indicate hereafter, if due consideration be not shown for the interests of the coming practitioners, and for the public through them.

The Difference between a Chemist and a Doctor.

The *Chemist and Druggist* quotes our recently-published observations respecting the inconsistency of the Pharmaceutical Trade Society, which prosecutes a grocer for selling poisons, yet insists on the right of the chemist to prescribe the said poisons without hindrance. Our contemporary infers that there is in our minds a confusion between the unlicensed practice of pharmacy (which, it says, is not forbidden by law), and the unlicensed sale of poisons, which *is* prohibited. No such confusion exists, and we allege that the unlicensed practice of pharmacy is—to all intents—strictly forbidden, because the greater includes the less; and it is not possible to dispense medicines without selling poisons; and the recognised pharmaceutist can always, and has—in many instances—put his foot on the unlawful dispenser, by making use of the Sale of Poisons Act. In the very copy of the *Chemist and Druggist* in which our article is quoted we find a full report of a prosecution by the Druggists' Trade Association against a co-operative store, under the provisions of the Sale of Poisons Act, for the sale *not* of a simple poison, or a vermin-killer, or a sheep-wash, but for dispensing a box of pills containing chloral and morphia, and sending them out without the "Poison" label attached. We entirely approve of such prosecutions, but we say that there is no moral distinction between the prosecution of the grocer for selling poison without a poison education, and the prosecution of the druggist for prescribing without a medical education. By enforcing the law against unlicensed poison-sellers the chemists and druggists abandon practically the fictions about the "custom of the trade," and "the liberty of the subject," upon which hang their defence from the charge of counter-doctoring.

The Profession and the Coming Parliamentary Elections.

The rumours of impending dissolution of the present Parliament remind us that it is time for us to issue a caution to the members of our profession in Ireland—voters in city, county, or university—that they be not too ready in promising their votes to anyone, or forgetful of their opportunity to make good use of their voices and their influence to advance their cause, It is to be regretted that medical men do not know their political strength, or are not sufficiently independent to avail themselves of it at the proper juncture. There are about 1,800 of our brethren actually resident in Ireland, of whom probably 1,200 at least are property holders in one form or another, and this number of votes would, if united, have force. But each and every medical man is on terms of intimacy with almost all the voters of his district, and can, if he pleases, do a good deal by his persuasion to decide a waverer, or bring up a voter who is careless about his suffrage, and the doctor can lose nothing, and may gain much, by exercising his influence openly. In the University of Dublin the profession is powerful, and might almost dictate its terms, and in large constituencies its vote is well worth having.

We hope that Irish medical men will not underrate their political value, and will put medical matters first in their political programme. For instance, what prison surgeon will support a Government which tolerates the proceedings of Mr. Charles Bourke and the Irish Prisons Board? What army medical man will give his vote for a Government which pertinaciously refuses to do him and his *confrères* justice? What Poor-law medical officer will give a vote for a candidate who refuses to pledge himself to support the fair claims of his class? We hope no one will be found to misuse his vote in such a way, for we fail to see anything in the contending politics of Liberalism, Conservatism, or Home Ruleism of such importance as to override medical interests. Again we advise our readers to "keep their powder dry," and promise no candidate until he has been duly interrogated on such points by the representatives of the medical men of Ireland.

Absorption of Dialysed Iron.

The Boston *Medical and Surgical Journal* notes that M. A. Luton, of Paris, states that he has successfully introduced subcutaneously from five to twenty drops of solution of dialysed iron without causing the slightest local disturbance. The immediate effects of this appear to be a sensation of warmth, as often agreeable as otherwise, spreading over the whole person, a determination of blood to the countenance, an increased mental activity, &c. He calls this condition a sort of ferruginous intoxication (*ivresse ferrique*), of which the persistence is somewhat dependent upon the size of the dose injected. The appetite in these cases is diminished rather than improved, but instead of the constipation which usually follows the administration of iron by the mouth, the bowels are pleasantly relaxed; also the urine is deeper in colour than that normally excreted, and yet its amount is not materially larger. He compares the effects of the hypodermic use of iron with that which follows the transfusion of blood, and states that they are similar. Finally, he says that any good pharmacist can prepare dyalised iron, and he is not interested is paying tribute to any special manufacturer.

On Infusoria in Expectoration.

In Virchow's *Archives* we read that great care is taken at Leyden in the examination of sputa, and some interesting facts have been discovered. Thus Konnenburg has

Digitized by Google

met with, in five cases out of six of gangrene of the lungs, infusoria of the family of monads, cerco monas, and monas lens. They are small rounded bodies of the form and size of a lymphoid cell, from which they are distinguished by their rapid movements and by a tail-like appendix.

They are easy to discover in recent expectoration, for their movement is most active. At the end of twenty-four hours it is impossible to find them. These organisms could not have penetrated accidentally the sputa. It is reasonable to believe that they come from the lung, and more especially that portion in a gangrenous state. Konnenburg has advanced the hypothesis that these monads may be the first cause of decomposition. However that may be, science is enriched by this little discovery.

Sprains treated by Hot Water.

Dr. Brinton, in the Philadelphia *Med. Reporter*, says that to treat sprains, the injured limb should be placed in hot water and boiling water be slowly added until the highest endurable temperature be reached. The limb is to be retained in the water a quarter of an hour, when the pain will have gradually disappeared.

The Digestibility of Milk.

Milk is one of the most useful articles of diet we possess, but unfortunately there are a large number who are unable to use it owing to its disagreeing, and producing unpleasant symptoms. Dr. Brush, New York, has contributed to the *New York Medical Journal* a very useful paper on the digestion of milk, which is of some practical value, and which explains the reason why cows' milk is indigestible. According to Dr. Brush, milk may be divided into two distinct varieties, according as it is the product of cud-chewing or non-cud-chewing animals, and that this is a distinction to which attention has not been previously drawn. The former class—that of the cud-chewers, to which that of the cow belongs—contains a variety of caseine which coagulates into a hard mass under the action of the digestive ferment, or during the lactic ferment. This coagulation takes place in the natural process of digestion with the calf. During the summer he had a calf in a stable, out of reach of any food, and gave it nothing but fresh milk from its mother; half an hour after the ingesta of milk he found the calf chewing the cud. After diligent inquiry, he finds that the same takes place with the sheep and the goat, the other domestic ruminant animals. He thinks we may from these facts explain the difficulty experienced by the human stomach in digesting the milk of ruminating animals.

The other variety of milk—that given by the non-cud-chewing animals, to which the human, equine, and canine races belong—does not under the action of rennet or acids coagulate into the hard mass we find in the cow's milk, but coagulates into small granular or flocculent masses easily diffusible. This fact explains very simply the advantages of kumyss prepared from cow's milk over the milk itself in the artificial feeding of children. In kumyss the caseine is—if we may be allowed to express it—practically regurgitated and chewed; *i.e.*, having been coagulated, it is re-subdivided and incapable of being coagulated under any acid or ferment.

There are other differences in the various kinds of milk which tend to modify the conditions under which it digests. For example, it is a well authenticated fact that the amount of caseine in milk is always in inverse proportion to the amount of sugar contained in it; the milk of the cud-chewer contains the smallest amount of sugar and the largest amount of caseine, while the milk of the non-cud-chewers contains, on the contrary, the largest amount of sugar and the smallest amount of caseine. Even in the case of cow's milk, in varying conditions of the animal's health, as the proportion of caseine diminishes, that of sugar increases. Another fact, too, deserves notice. The less sugar a given variety of milk contains, the more rapidly does lactic fermentation take place and consequent putrefaction follow. Now a milk containing a large amount of sugar will set up alcoholic fermentation, under conditions most favourable for lactic fermentation in a milk containing a small amount of sugar.

The bearing of this observation is that putrefaction follows lactic fermentation, whereas alcoholic fermentation precludes to a certain extent any form of putrefaction.

Here we have another reason for the beneficial effect of kumyss in the artificial feeding of children, for in kumyss the sugar is all changed into alcohol and its associates.

There is no doubt at this time that alcohol, when properly presented, is a hydro-carbonaceous food.

Credulity in Modern Times.

There has lately arrived at Birkenhead a strange phenomenon for this country—a lady doctor, who professes to be an Italian—Madame Enault. She has a magnificent turn-out, a chariot all mirrors and gold, with three splendid horses, said to be worth a hundred guineas each; seated on the top of this imposing vehicle are six musicians, dressed in fancy costume, cavalier hats, boots, and feathers. The lady herself is attired in a picturesque Italian costume, ornamented with dragons, stars, and other hieroglyphics. She also wears a gilded tiara and head-dress of beads, with flowing black hair. Just imagine the sensation she causes as she drives through the town with her band playing in the loudest strains, to the place where she is located, a piece of ground in Conway Street. This lady appears to cure every imaginable disease that human flesh is heir to—paralysis, extracting teeth, takes out encysted tumours, and all before the public almost instantaneously; but whether she does so in reality or not public opinion is divided. She is surrounded daily by a dense mass of two or three thousand people, including all classes of society, magistrates, merchants, shopkeepers and working men, all anxious and struggling to procure a bottle of the preparation that she calls "malachité," which she sells at 2s. per bottle. This she recommends almost for every complaint, for headache, toothache, neuralgia, &c., and to show what effect faith has in many cases of imaginary disease, a local chemist states in the *Pharmaceutical Journal*, that he examined it, and believes it to be a mixture containing tincture of cannabis indica together with glycerine and essential oils.

New Cements for Dental and other Purposes.

CHARLES SYLVESTER ROSTAING DI ROSTAGNI, of Philadelphia, has procured patents for preparing cements for dental and other purposes, which are compounds of pyrophosphates. A mixture of acid or neutral calcium phosphate is fused in a crucible together with zinc phosphate, or 1 part of calcium phosphate is fused with 10 to 30 parts of oxide of zinc, and enough ammonium phosphate to saturate the zinc oxide. The solidified, glassy mass is dissolved in dilute phosphoric acid; to the solution may be added a little magnesia or oxide of cadmium. The solution is evaporated, and when wanted for use the mass is dissolved in a little distilled water.

The Property in Prescription.

AT a recent inquest in Dublin upon the body of a lady, who had killed herself by repeated hypodermic injections, for which she had obtained the morphia upon an old prescription—the coroner, who is a medical man, expressed his opinion unreservedly that the repeated dispensing of medicines upon a prescription was an abuse which needed a legislative remedy. This is a question which has been warmly debated in America, where it is roundly insisted upon by a numerous party, that the prescription once dispensed, is the property of the physician or of the apothecary, but not of the patient, and that it ought not to be again compounded without a second visit to the doctor, or without returning to the same apothecary. There is no doubt, that in the case of the patient upon whom this inquest was held, and in others of the same class—for instance, when chloral once prescribed is afterwards used for intoxicating purposes—the unrestricted repetition of prescriptions works disadvantageously and, in such cases, a high class apothecary might very properly refuse to continue an endless repetition of the doses; but we cannot encourage for a moment the theory, that the right to that repetition is possessed by any one but the patient. At the last meeting of the Glasgow Chemists' Association, the President touched upon the subject, and said he had always considered that it was by right the property of the patient and not of the dispenser, although the American druggists thought differently, as they took possession of it, and pasted it into a book for the purpose, but they would give a copy if the patient wished one. As to repeats of prescriptions, he thought if anyone wished his prescription dispensed again and again the chemist had no right to refuse it, although it might keep some consultation fees from the physician. We fail to understand upon what principle a patient who has paid his fee for advice, and a recipe for medicine, should be obliged to seek leave from either doctor or dispenser to make unlimited use of the recipe which he has thus purchased, and however it might be justifiable for the dispenser to retain the original prescription for his own safety, we certainly think he is bound in equity to send to the patient, with the medicine, a true copy, so that the patient may please himself as to when and where he will have a repetition of it compounded.

The Health of Dublin.

THE deaths registered in the Dublin district during the week ending 8th November, represent an annual mortality of 30·1 in every 1,000 of the population. The average death-rate represented by the deaths registered in eight large town districts of Ireland (including Dublin), last week was 28·7. In twenty large English towns (inclusive of London, in which the rate was 22·0) the death-rate averaged 22·1; in Glasgow 20·0; and in Edinburgh 16·1. The mortality from zymotic diseases continues high, 42 deaths from these causes having been registered during the week, being 9 in excess of the average number for the corresponding week of the last ten years. With 3 exceptions, these deaths resulted from one or other of the seven principal diseases in this class, viz., 8 from small-pox, 5 from measles, 8 from scarlatina, 5 from diphtheria, 2 from whooping-cough, 6 from fever (1 typhus, 4 typhoid, and 1 simple continued fever), and 5 from diarrhœa: these 39 deaths are equivalent to an annual death-rate of 6·4 per 1,000 persons.

The deaths from small-pox are one over the average number for the previous five weeks, but the new cases of this disease admitted into the Dublin hospitals, although amounting to 23, are 4 under the average weekly number for that period. Twenty patients were discharged during the week, 8 died, and 83 remained under treatment on Saturday last, being 5 less than the number in hospital at the close of the previous week.

Three of the 8 deaths from scarlatina occurred in Denzille Street district, where 25 deaths from that cause were registered in the course of the preceding ten weeks. There were 61 cases of scarlatina under treatment in the principal Dublin hospitals on Saturday last; the admissions during the week numbered 17, being only 1 less than in the week ending 1st instant.

Tests for Colour Blindness.

A WELL-KNOWN ophthalmic authority, Professor Holmgren, advises the following simple tests for colour blindness: 1. A light green piece of wool is put aside from the others. The person to be examined has to add those of the same colour. The examination is continued until all the samples of the same shade have been added, or, besides them also, those of a grey, reddish, rosy colour. 2. A purple sample is put aside. The person who had by the former test been recognised as colour-blind has incomplete colour blindness if he adds only purple shades. Those who add besides them blue or violet, or both, are entirely red-blind. Whoever, besides the purple, adds green or grey, or both, is entirely green-blind. Those who, besides the purple, add red or orange, or violet, are respectively blue-blind. 3. Also a red sample may be put aside. The red-blind add green or brown shades, which appear darker to the healthy eye than the red of the sample. The green-blind will add shades of green or brown which appear lighter to the normal eye.

Health Resorts at Home.

IN connection with the subject to which we have just devoted two leading articles, may be mentioned a growing anxiety on the part of capitalists to make the Health Resorts in the United Kingdom more attractive, so as to compete with those of foreign countries, and to utilise such of the mineral waters for home consumption as have hitherto received but scant attention at the hands of the

Digitized by Google

profession and patients. The probability is that had many of these waters been bottled and put in the market years ago, foreign importations would not have assumed the magnitude of modern experience. Special attention is now being paid to Harrogate, where the Montpellier sulphur and iron springs are considered to offer ample scope for commercial enterprise. These springs have been purchased by the Chemists' Aërated and Mineral Waters Association, Limited, together with the extensive estate surrounding them, for £34,000. In this property is included the well-known Kissengen spring, chalybeate and other waters. As soon as arrangements are completed, it is intended to bottle these waters, and to cultivate a new home commerce in competition with those from foreign sources. Harrogate waters have never been favourites in bottle, owing to a cloudiness occasioned by an excess of oxygen; this objection Professor Attfield thinks can be overcome by aëration of the waters with carbonic acid gas immediately on their issuing from the spring. Thus treated, Professor Attfield thinks they "would take immensely with the public, and be valuable to the medical faculty." We wish the undertaking success.

The Treatment of Mydriasis.

De Wecker, in the *Gazette des Hopitaux*, says that the treatment of mydriasis must vary according to whether it is paralytic or spasmodic. All mydriases of paralytic origin are generally accompanied by a paralytic lesion of the ciliary muscle, while spasmodic mydriasis ordinarily leaves the muscle of accommodation intact. It will therefore most frequently suffice to investigate the *power of accommodation*, in order to determine whether the probable cause of the mydriasis be paralytic or spasmodic. If a patient, the subject of mydriasis, presents no disturbance of accommodation, we may declare that the cause of the mydriasis is spinal; while if the integrity of this be not preserved, the cause is cerebral. In this latter case the disturbances of accommodation are easily recognised.

Thus the subject of hypermetropia not being able to accommodate the eye regularly, is unable to see distinctly, whether near or at a distance; in emmetropia there is no longer clear perception of near objects, and in myopia the faculty of reading is reduced to the vicinity of the punctum remotum. One or other of these conditions, according to the case, will then indicate a cerebral lesion as the cause of the mydriasis. Of course all the subjects of mydriasis, whether paralytic or spasmodic, complain of the dazzling produced by light, dependent solely on the dilation of the pupil, but this disturbance will not be confounded with disturbance in accommodation, properly so-called. Mydriasis of *spinal* origin is a symptom of great value in prognosis, and often so in the diagnosis, of these affections. Thus it is an anticipatory symptom of loco-motor ataxy; and in general paralysis it is of great value. Eserine, pilocarpin, and continuous currents of electricity are recommended.

The Ready Road to Fortune and a Mayoralty.

The *Chemist and Druggist* honours with his portrait and biography Mr. Clarke, the proprietor of the irrepressible "Blood Mixture," who has recently reached the summit of all his greatness in being made Mayor of Lincoln. The history reminds us of the claimant's epigrammatic epitome of the world—three-fourths fools with money, and one-fourth sharp fellows with none—the three-fourths made for the purpose of maintaining the one-fourth. "Blood Mixture" Clarke is only 37 years of age. He opened a chemist's shop in Lincoln at the age of 19. He had no fortune to start with, but his business prospered, and in a few years he was able to take a larger shop. Waiting patiently, until he had saved a moderate fortune by his regular business, he at length resolved to launch out. He risked all he had. For the first three months he spent £500 a month, and for the remainder of the first year his advertising amounted to £1,000 a month. At the end of the year he had spent in advertising and printing some £15,000, and his balance-sheet showed that out of that he had sunk temporarily something like £7,000. But the property created was worth a great many times that amount, and he knew it. He still further extended his advertising, and by the end of the second year accounts were getting about straight. From that time onwards success was assured, and for some ten years or more the sale of the "Blood Mixture" has gone on increasing, while each year more than £20,000 has been invested in printing-ink.

At an ordinary meeting of the Council of the Royal College of Surgeons of England, held on Thursday last, Mr. Humphry, Mr. Marshall, and Mr. Savory were re-elected members of the Committee on Examinations in Anatomy and Physiology.

The lowest death-rate ever registered at Hastings, occurred during the quarter ending September 30th, being only 12 per 1,000 of the population. The knowledge of this is especially valuable to the profession, which sends so many patients to southern health resorts.

At the Primary Examination in Anatomy and Physiology at the College of Surgeons, England, last week, 19 candidates out of the 71 having failed to acquit themselves to the satisfaction of the Board of Examiners, were referred to their studies for three months, including three who had an additional three months.

At Cambridge a lady is acting under the direction of Dr. Michael Foster and Mr. Balfour, as demonstrator to the students who are working at physiology and comparative anatomy under the auspices of the Association for the Higher Education of Women. Irrespective of the entries at Girton College, eighty-two ladies are now attending the lectures at Cambridge arranged for the sex, and a large number are formally engaged in the study of natural science.

According to the Registrar-General's returns the rates of mortality per 1,000 last week in the principal large towns were—Brighton 15, Oldham 15, Edinburgh 16, Leicester 18, Sheffield 19, Portsmouth 19, Glasgow 20, Salford 21, Manchester 21, Birmingham 21, Bradford 22, London 22, Newcastle-upon-Tyne 22, Plymouth 22, Nor-

Digitized by Google

wich 23, Bristol 23, Nottingham 24, Liverpool 24, Hull 25, Leeds 27, Wolverhampton 27, and the highest rate 30 in Dublin and Sunderland.

THE Queen's letter has been received appointing R. O'Brien Furlong, Esq., barrister-at-law, Secretary to the Royal Sanitary Commission, Dublin, in the room of W. Jerrold Dixon, Esq., deceased. Mr. Furlong has well earned his office and is a valuable accession to the Commission. He knows, probably, more of Irish sanitary law and of the sanitation of Dublin than any other man outside the medical profession, and is fully competent to aid the Commissioners in the production of a valuable report.

THE *City Press* records the fact that a wealthy London parish, having of late considerably augmented the income arising out of a charitable bequest, and finding that the proceeds far exceed the provisions of the ancient donor, has decided to apply to the Charity Commissioners for authority to make the following donations, viz.:—The London Hospital, £1000; Metropolitan Free Hospital, £500; King's College Hospital, £250; Victoria Park Hospital, £250; Westminster Hospital, £250; and the City of London College, £250, making a total of £2,500, in addition to advancing the allowances to the qualified recipients of the charity 25 per cent. The London Hospital has before received from the same source a similar gift of £1,000.

THE NEW SCHEDULE OF THE QUALIFICATIONS OF CANDIDATES FOR THE ARMY MEDICAL SERVICE.

THE following is a new Schedule, just issued, of the qualifications necessary for candidates desirous of obtaining commissions in the Army Medical Department, with the conditions of service:—

1. Every candidate for a commission in the Army Medical Department must be twenty-one years of age and not over twenty-eight years at the date of commencement of the competitive examination. He must produce an extract from the register of his birth, or in default, a declaration, made before a magistrate by one of his parents or guardians, giving his exact age. He must also produce a recommendation from some person of standing in society—not a member of his own family—to the effect that he is of regular and steady habits, and likely in *every* respect to prove creditable to the Department if a commission be granted; and also a certificate of moral character, from the parochial clergyman, if possible.

2. The candidate must sign a declaration upon honour that both his parents are of unmixed European blood, and that he labours under no mental or constitutional disease, nor has any hereditary tendency thereto, nor any imperfection or disability that can interfere with the efficient discharge of the duties of a medical officer in any climate; also that he does not hold, and has never held, any commission or appointment in the public services.

His physical fitness will be determined by a board of medical officers, who are required to certify that the candidate's vision is sufficiently good to enable him to perform any surgical operation without the aid of glasses. A moderate degree of myopia will not be considered a disqualification provided it does not necessitate the use of glasses during the performance of operations, and that no organic disease of the eyes exists.

The board must also certify that he is free from organic or other diseases, and from constitutional weakness, or tendency thereto, or other disability of any kind likely to unfit him for military service in any climate.

3. *Certificates of age, registration of diplomas, &c., and of character, must accompany the declaration when signed and returned.*

4. Candidates will be examined by the Examining Board in the following compulsory subjects, and the highest number of marks attainable will be distributed as follows:—*a.* Anatomy and Physiology, 1,000; *b.* Surgery, 1,000; *c.* Medicine, including therapeutics, the diseases of women and children, 1,000; *d.* Chemistry and Pharmacy, and a practical knowledge of drugs, 100. (N.B.—The examination in medicine and surgery will be in part practical, and will include operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside.)

The eligibility of each candidate for the Army Medical Service will be determined by the result of examination in these subjects only.

Examinations will also be held in the following voluntary subjects, for which the maximum number of marks will be—French and German (150 each), 300; natural sciences, 300.

The knowledge of modern languages being considered of great importance, all intending competitors are urged to qualify in French and German.

The natural sciences will include comparative anatomy, zoology, natural philosophy, physical geography, and botany with special reference to materia medica. The number of marks gained in both the voluntary subjects will be added to the total number of marks obtained by those who shall have been found qualified for admission, and whose position on the list of successful competitors will thus be improved in proportion to their knowledge of modern languages and natural sciences.

5. After passing this examination, every qualified candidate will be required to attend one course of practical instruction at the Army Medical School as a probationer on—(1) Hygiene, (2) Clinical and Military Medicine, (3) Clinical and Military Surgery, (4) Pathology of Diseases and Injuries incident to Military Service.

6. In future, service in the Army Medical Department will not be limited to ten years, but executive medical officers will be placed on the retired list at fifty-five, and administrative officers at sixty years of age.

7. Candidates must possess two diplomas or licences—one to practise medicine and the other surgery—and be registered under the Medical Act in force in the United Kingdom at the time of their appointment.

8. The terms of the new Warrant for the Department are not finally settled, but the rates of pay and retired pay, stated below, have been sanctioned.

Full Pay.—Surgeon-General, £2 15s. daily; Deputy Surgeon-General, £2 daily; Brigade-Surgeon, £1 10s.; after 5 years in the ranks £1 13s. daily; Surgeon-Major, £1, after 15 years' service £1 2s. 6d., 20 years' service, £1 5s., 25 years' service £1 7s. 6d. daily; Surgeon, £200, after 5 years' service £250 yearly, after 10 years' service 15s. daily; Surgeon on Probation 8s. daily. (This scale does not include allowances for lodgings, fuel, and light, and for servant.)

Gratuity and Retired Pay.—Surgeon and Surgeon-Major, after 10 years' service £1,250, 15 years' service, £1800, 18 years' service £2,500 gratuity; Surgeon-Major, after 20 years' service, £1, 25 years' service £1 2s. 6d., 30 years' service £1 5s. daily; Brigade Surgeon, after 20 years' service £1 7s. 6d., 30 years' service £1 10s. daily; Deputy Surgeon-General, £1 15s. daily; Surgeon-General, £2 daily.

Temporary Half-Pay.—Medical Officer, under 5 years' service, 6s., after five years' service 8s., 10 years' service 10s., 15 years' service 13s. 6d. daily.

Digitized by Google

Relative Rank.—Surgeon-General, as Major-General; Deputy Surgeon-General, as Colonel; Brigade Surgeon and Surgeon-Major of 20 years' service, as Lieutenant-Colonel; Surgeon-Major of less than 20 years' service, as Major; Surgeon, as Captain; Surgeon on Probation, as Lieutenant.

HUMAN ANATOMY AND PHYSIOLOGY—PARTS I., II., III. (a)

Witkowski's Movable Atlases.

The publishers are conferring a distinct boon upon students and practitioners in this country by issuing English editions of the valuable Movable Atlases of Prof. Witkowski.

Part I. is a very ingenious, and at the same time accurate, representation by coloured plates of the various structures of the neck and trunk. The surface view exhibits the anterior part of the body covered by its muscles, but divested of the skin, showing on the right side the external parts, such as the obliquus externus, and its aponeurosis; and on the left side the left half of the rectus abdominis. On reversing this external plate, the other side shows the deeper layers, such as the obliquus internus, the transversalis fascia and muscle, &c. The overlying parts being then removed, the subjacent plate represents the still deeper parts, such as the ribs and the intercostal muscles, the stomach and intestines, &c.; and these again being lifted up, the very deepest structures are exposed to view, such as the heart, the lungs, the liver, the abdominal aorta, the vena cava, &c. The simple contrivance by which these views are successively exhibited is worthy of all admiration, and as every part has a number, with a corresponding explanation on the accompanying printed table, there is not the least difficulty in assigning the anatomical description to each. To those who desire to possess some knowledge of the construction of the human frame as revealed by anatomy, as well as to those who are anxious to revise or to strengthen their previous anatomical knowledge, this Atlas must be a most valuable boon; and as the price is wonderfully low, there is no doubt that many individuals, as well as educational establishments, will readily avail themselves of this opportunity of acquiring the information afforded by Dr. Witkowski's pictorial delineations. The fidelity of the representations (making allowance, of course, for the difficulty of drawing solid or hollow parts on flat surfaces), is unquestionable; and the explanation of the figures having been translated by so accurate a French scholar, and so good an anatomist, as Dr. R. H. Semple, there is not the slightest Gallicism to embarrass the English reader in his comprehension of the various objects depicted.

The text accompanying the Atlas is by the same author and translator, and is a brief *résumé* of the anatomy and physiology of the human body. The different functions of the body are described in succession, together with the structures by which each function is performed; and while a great amount of valuable knowledge is compressed in a very narrow space, the descriptions are so clear as to be intelligible to the meanest capacity.

Part II.—In this part—"The Mechanism of Voice, Speech, and Taste"—Mr. Lennox Browne has not only given us a clear, faithful, and flowing translation of Prof. Witkowski's text, but has enriched it with many valuable original remarks and notes, the outcome of his own extensive experience, or drawn from recent authorities. This of course adds greatly to the value of the text, which, though brief and succinct, is a very complete account of the anatomy and physiology of the organs of voice, speech, and taste. For those who, not having the opportunity of study on the cadaver, desire to increase their knowledge of the anatomy and physiology of these important organs, these movable Atlases, with their accompanying text, will be found invaluable, and form, indeed, a "royal road" to knowledge.

Part III.—"The Female Organs of Generation and Reproduction"—is really a marvel of ingenuity, and will be found of great value in imparting an accurate knowledge of the relations of a region the study of which is frequently much neglected.

In the accompanying text Dr. Palfrey has contented himself with translating into good English the words of Professor Witkowski. He tells us in his preface that he at first intended to add some original observations to the text in the form of notes, but subsequent consideration convinced him that he would best be "carrying out the views of the publishers by leaving the translation as it is, and simply asking those who study the essay to bear in mind the fact that our neighbours express their physiological views somewhat more freely than writers on the same subject do with us." Making allowance for this, the text furnishes us with a useful compendium of the anatomy and physiology of the female generative organs.

At the present time, when anatomy and physiology are not exclusively confined, as they once were, to the schools of medicine, but are studied in a much wider sphere, the present contributions of Dr. Witkowski will be welcome to all classes of the public, and especially to those who are engaged in the work of instruction.

We can, therefore, heartily recommend this series of Atlases as worthy of attention by all our readers, and trust the publishers will soon complete the series, according to promise.

(a) I. "A Movable Atlas of the Human Body (Neck and Trunk), showing the positions of the Internal Organs by means of Superposed Coloured Plates." By Professor G. J. Witkowski, M.D., Member of the "Faculté de Médicine de Paris." The Text translated into English and edited by R. H. Semple, M.D., F.R.C.P.L.

II. "A Movable Atlas of the Various Organs of Voice, Speech, and Taste by means of Superposed Coloured Plates." By Prof. Witkowski, M.D. The Text translated into English and edited by Lennox Browne, F.R.C.S. Ed., Senior Surgeon Central Throat and Ear Hospital.

III. "A Movable Atlas of the Female Organs of Generation and Reproduction." By the same author. Translated by James Palfrey, M.D., M.R.C.P. Lond., Senior Obstetric Physician to the London Hospital, &c. London: Baillière, Tindall, and Cox.

Correspondence.

THE REMOVAL OF FOREIGN BODIES IN THE EAR.

To the Editor of the Medical Press and Circular.

Sir,—Amongst the minor operations of surgery there are few which are sometimes more troublesome than the removal of foreign bodies from the ear. The subject has recently been brought under the notice of the readers of the *Medical Press* by the cases reported in the issue for Oct. 29, by Dr. Rawson, of the Carlow County Infirmary. Dr. Rawson says "it is often a tedious, difficult, and painful operation to extract them [foreign bodies]. I have used all kinds of forceps, and crooks, and wire loops, with varying success; but the operation is always tedious, and blood is almost always drawn." It would seem from this that the precepts which aural surgeons have for years striven to inculcate have not yet made much impression, as Dr. Rawson makes no mention of having used the syringe, which is, in all but a few very exceptional cases, the *only* instrument which should be employed for the removal of foreign bodies from the ear. The cases are *extremely rare* in which the syringe, skilfully and perseveringly used, will not suffice to cause the expulsion of the offender. I could quote the words of many authorities on aural practice in support of this assertion, and could instance many cases in my own practice and that of others in the same direction; but such a course is unnecessary, and would occupy too much space.

I would, however, make a few remarks on the subject of foreign bodies in the ear in general, and their removal. In the first place it should be remembered that a hard substance—as a bead, a stone, &c.—which will not absorb moisture, may remain in the meatus without causing any injury. It is only insects or vegetable substances which swell by the absorption of moisture, which do harm if left alone. If, therefore, any hard body, as a stone, cannot be removed by syringing, it is far better to leave it alone for a time; and very likely at a future date its removal may be easily effected. Another thing to be remembered is that no

Digitized by Google

attempt should ever be made at the removal of a foreign body which cannot be seen.

Incalculable and fatal injury may be, and has been, done by haphazard groping about with picks and forceps, after a foreign body, which perhaps is not in the ear at all. Thirdly, force should never be used for the extraction of a substance. If a patient is brought complaining of a foreign substance in the auditory canal, a strong light should be thrown into the meatus through a speculum, by means of a laryngoscopic reflector or other concave mirror, and the body *seen*. Its removal may then be attempted by means of the syringe and warm water. In using the syringe for this purpose, a fine nozzle should be employed, and the auricle drawn upwards and backwards so as to straighten the meatus as much as possible. The jet of water should be directed along the upper wall of the canal, when it will usually get behind the foreign body and expel it. The removal may often be facilitated by turning the patient on his side, with the affected ear downwards, and syringing from below.

If there is much swelling and inflammation leeches may be applied to the tragus, and fomentations and warm lead lotions applied. On the subsidence of the swelling, the syringe will usually expel the offending substance.

Instruments, as forceps, probes, &c., should be employed only under very exceptional circumstances, and when a fair trial of the syringe has failed. When used, it should be only under good illumination, so that the operator may follow the instrument with his eyes.

A smooth round substance, as a marble, may often be removed by the use of a brush dipped in glue or coaguline, which being placed in contact with it, is allowed to harden; and then brush and body are withdrawn together.

In conclusion, I would repeat the belief that there are very few cases in which the syringe will not suffice to remove the foreign body. At any rate, a fair trial should always be given to it before resorting to any more dangerous instrument.

Yours, &c.,

W. Douglas Hemming, F.R.C.S.Ed.

Bournemouth.

THE MICROSCOPICAL SOCIETY'S TRANSACTIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I have just seen the criticism, in your issue of the 22nd ult., on the Transactions of the Microscopical Society, and I desire to express my entire concurrence in its tone, which is certainly only just and proper. Since the suppression of an independent source of communication between microscopists (*The Microscopical Journal*), practical questions have made way for twaddle, and the Society itself has condescended to discuss old and pirated inventions, which are constantly served up as something new. This is done in so barefaced a manner that I have at length been driven to send in my resignation as a member. I regret this, after being connected with the Society as Member, Councillor, and Vice-President for upwards of thirty years.

As an evidence of what I have experienced in common with other old workers at the microscope, I may refer you to a recent claim set up by Dr. Edmunds to my "Immersion Paraboloid Illuminator," a piece of apparatus I made more than twenty-three years ago. Dr. Edmunds, in a paper read before the Quekett Club, says: "The paraboloid described by Mr. Wenham is not like mine, either in its peculiar effects or that of the method of working or applying it; the two instruments do not in the least resemble each other." The mendacity of this assertion is very remarkable, since it is well known that all truncated paraboloids are identical, and the effects produced are precisely alike. What I have a just right to complain of is that the President of the Royal Microscopical Society, in the new edition of his book on "The Microscope," ascribes this invention of mine to Dr. Edmunds. I hope, therefore, that outside independent criticism, such as you have favoured your readers with, will place a salutary check on such injustice for the future.

Yours, &c.,

F. H. Wenham.

164 New Bond Street, 7th Nov., 1879.

[We have not seen the new edition of Beale's work on "The Microscope" to which Mr. Wenham refers. But Dr. Beale certainly ought to have known that Dr. Edmunds wrote in the following terms to the editor of *Nature*, July 11th, 1878:—"The Immersion Paraboloid Illuminator exhibited at the recent *soirée* of the Royal Society, as designed by me, proves to have been anticipated in principle and construction by Dr. John Barker, of Dublin, from whom a paper on the subject will be found in the proceedings of the Royal Irish Academy for 1870. An immersion parabaloid illuminator was also described by Mr. Wenham in the 'Transactions of the Microscopical Society' for 1856. My paper on the subject appeared in the *Monthly Microscopical Journal* for August, 1877, but as that journal is now defunct, I ask you to allow me to credit these gentlemen with a priority which on perusing their papers I find to be due to them." Dr. Beale will, no doubt, see that some explanation is justly due to Mr. Wenham in this matter.—Ed. M. P. & C.]

A PROBLEM FOR DEBATE—HEALTH RESORTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Your excellent leaders on this subject has given me great pleasure. If there exists a good medical debating society in London or Dublin, I would suggest a very important subject for consideration, which admits of fair arguments *pro* and *con*, and affects not only the profession, but the public. It is a very comprehensive proposition. "Ought medical men to send their phthisical patients, in the last stage, to foreign health resorts, thereby entailing heavy expenses, often difficult to meet, on many families, and impoverishing the health resorts in our own country to the enriching of other countries."

I will not argue the question, but may briefly direct attention to the principal arguments:—

Consumption but rarely strikes in vain; in the last stage death must soon come, and it is, I imagine, sweeter to die surrounded by loving friends, amidst the sound of our dear old English tongue, knowing that up to the last loving English hands will smooth the passage to eternity, and even that after death what remains will be laid in English soil, where friends may come and place a flower. The grave in a foreign watering place is so far away from home. This is the sentimental side, as it is called—ask loving mothers what they call it?

The pecuniary side, or the practical, comes next. A journey to San Remo, or any other similar sanatorium, is very expensive with an invalid. It hampers families very much to incur this outlay. It is useless in most cases. Why not utilise our own health resorts? Have we not such places in England? Why not save the money? Why not spend English money in encouraging English enterprise? The other side? I leave the other side for the debate.

Yours faithfully,

London. M.D. Lond.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Whether your articles on residence abroad may have the happy effects they are intended to produce I know not, but in any case you will have earned the thanks of thousands in England who now mourn for loved relations cruelly sent to die in a foreign country.

Yours truly,

London, Nov. 6th, 1879. A Victim.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—As one personally interested in one of our English health resorts, I am pleased to find that there is a journal sufficiently independent to attack the fashionable ring, who send so many patients abroad, without due consideration either of their purse or of the claims of our English watering places and sanatoria. There are many suitable places in England for patients with lung consolidation.

Yours faithfully,

A Landlord.

Bournemouth, Nov. 7th, 1879.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Dear Sir,—In your issue of October I think I fully ex-

Digitized by Google

posed the illogical position of Dr. Clifford Allbutt in reference to Davos, and I am pleased to find that you have devoted some space to a somewhat similar subject, and thoroughly exposed the vagaries of the thoughtless or sanguine young medical men who are so ready to take up new ideas, or to countenance new places only because they are new. The same men seem to be imbued with a thorough love of everything foreign. This I would not object to if it were only regulated by some rational principle.

The outside public have a fair right to take this subject up, and if some of our other first-class journals, as the *Spectator*, *Saturday Review*, were to take the matter up, I have no doubt the death-blow would be struck to that custom which which has long been a reproach to medicine.

Yours faithfully,

London, Nov. 8th, 1879. INQUIRER.

A HINT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Remembering that medicine, in one of its phases, was included in the original appropriation scheme of the Irish church surplus, permit me to ask you if any steps have been taken to secure such a valuable boon?

A large sum of the surplus has recently and very properly been appropriated to educational purposes. One fourth of that sum would provide ample infirmary accommodation in every union; and also a sufficient fund for promoting and maintaining the compulsory superannuation of dispensary medical officers.

Fancy legislation, honoured with the endearing title *Permissive*, is evidently not adapted to the financial genius of the people. In the case of National education it proved a complete failure; in the case superannuation of medical officers it is still a mockery and a snare, tending directly to the cultivation and exhibition of the meanest feelings in human nature.

The recent and present proceedings of boards of guardians almost everywhere indicate the animating and governing spirit which will, with energy, manifest itself in future in the total annihilation of this one-sided and very partial good. Whoever heard of the Local Government Board enforcing superannuation by a *sealed order*? Therefore, I say unto you, *ask, seek, knock*, for "yet there is room."

Yours, &c.,

D. D. D.

University of London.—The following have just passed the second M.B. examination :—

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

OUR NORTHERN CORRESPONDENT.—Your weekly parcel had not arrived at time of going to press.

ALPHA.—There are no cottage hospitals in Ireland so far as we are aware.

DR. ANDREW CLARK will please receive our best thanks.

ASSOCIATION OF SURGEONS PRACTISING DENTAL SURGERY.—The first meeting of the session will take place this evening (Wednesday), at 8.30, in the rooms of the Medical Society of London.

EPSOM COLLEGE EXHIBITIONS.—A competitive examination for admission on exhibitioner's terms will take place in December. Forms of application may be obtained of the Secretary at the offices, 37 Soho Square, London. Candidates must be sons of deceased or invalid members of the profession.

THE METRIC SYSTEM.

THE metric system of weights and measures is based on a standard measure represented by the METRE: a unit of length equal to a little more than one yard—viz., 39·370 English inches. French geometricians intended this standard should have reference to the circumference of the earth, and therefore the metre is estimated as

The one-ten millionth part of the distance between the Equator and the Pole, or 39·370 English inches.

It is divided into tenths, *decimetres*, hundredths, *centimetres*, and thousandths, *millimetres*. The multiples are tens—*decametres*, hundredths, *hectometres*, and thousandths, *kilometres*. For *area* and *capacity* we have *square* metres, decimetres, &c., and also *cubic* metres, millimetres, &c.

The *Litre* is the unit of weight for fluid measures, and is the term used to denote one cubic decimetre, or 1¾ pints English. It is divided into 10ths, 100ths, 1,000ths, &c.

The *Gramme*, or the weight of one cubic centimetre of water at the temperature of 4 degrees centigrade, is the unit of weight, and equals 15½ grains. It is also subdivided into 10ths, 100ths, 1000ths, &c.

HARVEIAN SOCIETY OF LONDON.—On Thursday, Nov. 20, at 8.30 p.m., Dr. W. Squire, "The Action of Salicine and Salycilic Acid in Rheumatism."—Mr. Osman Vincent, "Congenital Talipes in the Adult."—Mr. Walter Pye, "The Present Position of the Operation of Nerve-stretching."

THE TOPICAL USE OF ERGOT.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Our attention has been called to a note in your issue of Oct. 15, page 389, in which you advise the topical use of ergot in chronic conjunctivitis. We wish to call your attention to our ophthalmic discs of ergotine as a convenient way of bringing ergotine into contact with the tissues and rendering it wholly available for the purpose intended. Bonjeau's ergotine is the basis of our preparation, and of the activity of this substance there is no question.

We are now experimenting upon the sclerotic acid of Dragendorff,

Digitized by Google

which is said to be the real active principle of ergot, and we hope in a few days to offer this to the profession for trial.

We are, Sir,
Your most obedient servants,
143 New Bond Street, London. SAVORY & MOORE.

THE HOMES OF MEDICAL MEN.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Your inquiries on this subject in this week's MEDICAL PRESS are very appropriate and important, and it is to be hop d they will have the effect of causing medical men to view this matter in the light in which you put it.

Recognising the importance of this matter, Dr. John Drysdale of this town built himself a house in 1861 in which a complete system of ventilation was introduced; and in 1867 I also built one for my own residence, adopting the same plan. One of us read a paper on the subject before the Architectural Society of Liverpool and before the Institute of British Architects in London. I forward you a copy of the letter. Your mentioning these facts in your excellent journal may induce other medical men to do the same. Under our directions Messrs. Soon, of Charing Cross, have published a full explanation of the plan, with illustrations, &c.

I am, Sir, yours truly,
117 Grove Street, Liverpool, JOHN W. HAYWARD.
November 13.

VACANCIES.

Bristol Royal Infirmary.—House Surgeon. Salary, £100, with board, &c. Applications to the Secretary on or before Dec. 1.

Londerry Union, Johnstown Dispensary.—Medical Officer. Salary, £120, with fees, and £15 as Medical Officer of Health. Election. Nov. 27.

Gort Union, Gort Dispensary.—Medical Officer. Salary, £120, with fees, and £10 as Medical Officer of Health. Election, Nov. 22.

Great Northern Hospital, London.—Two Physicians. Honorary. Applications to the Secretary on or before Dec. 4.

Hospital for Children, Great Ormond Street, London.—House Surgeon. Salary, £50, with board, &c. Applications to the Secretary on or before Nov. 27.

Queen's College, Belfast.—Professorship of Chemistry.

Royal Free Hospital, London.—Assistant Surgeon on the Staff. Applications to the Secretary on or before Nov. 26. (See Advt.)

APPOINTMENTS.

BERNSTEIN, M. J., M.B., Assistant House Surgeon to the Wolverhampton and Staffordshire General Hospital.

CLARKE, J. P., L.K.Q.C.P.I. & L.M., L.R.C.S.I., Certifying Factory Surgeon for the District of Castleblayney, co. Monaghan.

CORDNER, L. M., L.K.Q.C.P.I., L.R.C.S.I., Certifying Factory Surgeon for the District of Aughnacloy, co. Tyrone.

CREAGH, J., L.R.C.P.Ed., L.R.C.S.I., Medical Officer and Medical Officer of Health for the Mallow Dispensary District of the Mallow Union, co. Cork.

DUFF, A, L.K.Q.C.P.I. & L.M., L.R.C.S.I., Medical Officer and Medical Officer of Health for the Castlerea Dispensary District of the Castlerea Union, co. Roscommon.

GABBETT, H. S., M.B., L.R.C.S.I., a Physician to the St. Marylebone General Dispensary.

LYNDON, G., L.K.Q.C.P.I. & L.M., L.R.C.S.I., Certifying Factory Surgeon for the District of Ballinagh, co. Cavan.

PEELE, E., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer to the Throat and Ear Hospital, York Street, Dublin.

PENTLAND, A., M.B., L.R.C.S.I., Assistant House Surgeon to the Metropolitan Free Hospital.

SANDELS, W. J., L.F.P.S.G. & L.M., M.R.C.S.E., Certifying Factory Surgeon for the District of Lisnaskea, co. Fermanagh.

TAYLOR, J., L.R.C.S.I., L.K.Q.C.P.I., Medical Officer to the Tandragee Dispensary, Banbridge Union.

Births.

DE LA MOTTE.—On Nov. 8, at Thorndean, Staines, the wife of P. W. De la Motte, M.R.C.P., M.R.C.S., of a daughter.

GELL.—On Nov. 13, at St. John's Lodge, Kensal Green, the wife of T. S. Gell, M.D., of a son.

GEOGHEGAN.—On Nov. 9, at Ivy House, Redcar, the wife of Surgeon Geoghegan, A.M.D., of a daughter, prematurely.

HUMPHREYS.—On Nov. 12, at Trinity Square, London, E.C., the wife of F. W. Humphreys, F.R.C.S., of a son.

Marriages.

DILLON—DE COURCY.—On Nov. 6, at Tarbert, co. Kerry, John T. Dillon, M.D., M.Ch., Listowel, to Anna Margaret, youngest daughter of the late Henry G. De Courcy, Esq., Dooncaha Lodge, co. Kerry.

HILL—TENDER.—On Nov. 7, at Calcutta, Captain Herbert F. Hill, 44th Regiment, to Mary, daughter of J. Tender, M.D., J.P., of Keale House, co. Cork. (*By Telegraph.*)

Deaths.

ARDING.—On Nov. 6, at Wallingford, Surrey, Willoughby Arding, M.D., aged 74.

COLLINS.—On Nov. 9, at Wanstead, Frederick Collins, M.D., aged 53.

DODSWORTH.—On Nov. 2, at Turnham Green, Frederick C. Dodsworth, M.R.C.S.E., aged 74.

FULTON.—On Nov. 11, at Saintfield, co. Down, Matilda, wife of Thos. Fulton, M.D., aged 35.

PICKOP.—On Nov. 4, at Great Salkeld, Eli Pickop, M.R.C.S.E., aged 64.

WADE.—On Nov. 12, at the Royal Victoria Yard, Deptford, Seaton Wade, Fleet-Surgeon Royal Navy.

WANTED.—A QUALIFIED MEDICAL MAN.
Address, stating qualifications, age, reference, salary wanted, And if willing to assist in office work, T. B. Clarke, Son, and Platt, advertising Agents, 85 Gracechurch Street, E.C.

CASH ADVANCES MAY BE OBTAINED by Members of the Medical Profession who may desire temporary accommodation pending the collection of their accounts.
No charge of any kind unless the business is carried out.
Apply to the Imperial Discount Company, Limited, 8t. Clement's Lane, E.C. WM. BAKER, Manager.

EPSOM COLLEGE EXHIBITIONS.—NOTICE is hereby given that a COMPETITIVE EXAMINATION for the admission of Boys as Exhibitioners at Epsom College will take place in December next The Exhibitioners will pay £30 a year each for education, board, lodging, &c., instead of the £48 or £51 usually charged. Candidates must not be over fourteen years of age, and must, by the second bye-law of the College, be "sons of some of the less fortunate members of the medical profession." The parents will be required to make a confidential statement as to their income, the number of their children, and their means of educating them. A Committee of the Council will consider the claims of candidates, and make a list of such as they find to be eligible, and these will compete for the Exhibitions on a day to be fixed in December. All particulars and forms of application can be obtained at the office, 37 Soho Square. The forms must be returned to the Secretary by the end of the current month of November. The successful competitors will be admitted on the re-opening of the College in January.

By order of the Council,
ROBERT FREEMAN, Secretary.
37 Soho Square, London. Nov. 12th, 1879.

TO BE SOLD, THE HOUSE AND LANDS OF BELLEVUE, situate at Tolka Bridge, near Finglass, in the county of Dublin, about three miles from the General Post Office, with the Outhouses and Offices thereon, containing in the whole about 28 Irish acres.
These extensive Premises, which have been used for many years as a Private Lunatic Asylum, in the hands of the late Mr. GREGORY, are peculiarly adapted for this purpose, and would also be very suitable for any Public institution requiring a great deal of accommodation
The Building contains several Reception-rooms, Bed-rooms sufficient for the accommodation of about 50 patients, with all the accommodation necessary for a large institution, besides Coach-house and stabling for four horses, Cow-sheds, Barn, and other Out-offices, all in good repair. The land is of first-rate quality, and the grounds are tastefully laid out and generally attractive.
For particulars and Conditions of Sale and all further information apply to HENRY T. DIX, Solicitor for vendors, 61 Upper Sackville Street, where orders to view the premises may be obtained

Intermediate School of Art, IRELAND.

ANATOMICAL & PATHOLOGICAL SECTION.

THE Class for Anatomical and Pathological Modelling and Construction of Wax Coloured Preparations, Drawing, and Colouring in Water, will open on 1st October, under the Direction of JOHN WOODHOUSE, A.R.H.A., at

11 HARRINGTON STREET,

Medical Men and Students in Medicine and Surgery are specially invited as this Class is intended for them chiefly.

Syllabus, Fees, and Further Particulars may be had on application from—

WILLIAM H. ARCHER,
(*Surgical Artist*) *Secretary*,
28 PLEASANT STREET,
DUBLIN.

MACINTOSH WAREHOUSE.

TO THE MEDICAL PROFESSION.

POYNTZ, PEPPARD., and CO.
INDIA-RUBBER, GUTTA-PERCHA,
AND PORTMANTEAU MANUFACTURERS,
52 GRAFTON STREET, DUBLIN,

INVITE an Inspection and Comparison of the Prices and Quality of their

Catheters, Enemas, Injection Bottles, Bougies, Pessaries, Ice Bags, Water Bottles, Urinals, Water Beds, Air Cushions, Ear Syringes, Eye and Ear Douches, Spray Diffusers, Hospital Sheeting. *Surgical Hosiery.*—Elastic Stockings, Elastic Leggings, Elastic Knee-Caps, Elastic Socks.

IRISH POOR-LAW INTELLIGENCE.

IRISH MEDICAL ASSOCIATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with interest the letters of correspondents in your late issues concerning the grievances of the Poor-law Medical Officers in Ireland, and though the schemes of your correspondents are not likely to meet with general support, for obvious reasons, still it is gratifying to find that there are some members of the the Poor-law Service in Ireland who are not content to remain in the hopeless condition of men trying to serve not alone two masters, but many.

Since I have been resident in this country I have received several communications from the Irish Medical Association asking me to join their ranks, but one of the reasons they put forward why I should do so was that, if I recollect aright, it only numbers about one-third of the total practitioners in Ireland. Now, considering that it has been in existance for twenty-six years since its re-establishment, it makes a very grave charge against itself and the benefits it says it confers, when it admits that so large a majority of the practitioners of the country hold aloof from it.

On looking over the list of officers of the Irish Medical Association I find that it is largely composed of Dublin hospital physicians and surgeons, a class of gentlemen who can have but little direct interest in the trials and struggles of the dispensary doctor.

I have been in the habit of reading certain lengthy documents printed in the poor-law intelligence of your excellent journal, purporting to be letters addressed by the hon. sec. of the Irish Medical Association to the Local Government Board about matters relating to the Irish Poor-law Medical Service, and all I need say concerning them is that I fancy they are regarded by the clerks of that circumlocution office as so much waste paper when not backed up by the general voice of the profession or issued by a body capable of commanding attention.

But Sir, I am not disposed to criticise alone what seems to me to be the failings of the Irish Medical Association, without suggesting what I consider to be the practical remedies, and this I shall endeavour to do as briefly as possible on the present occasion.

First, as to the important question of funds. I conceive that the way to increase the number of subscribers would be for the council of the Association to induce some one member in each union or district to collect the subscriptions personally, not by letter, and try to get all the practitioners in his neighbourhood to join. I suggest this because I know how much busy men dislike the trouble of sending subscriptions by post, how much more freely it would be paid on the spot to a friend asking for it.

Secondly, I believe the Irish Association might take pattern in many things with advantage from its contemporary, the British Medical. Let the council be elected by the numbers in each county, and *on the spot*, not in Dublin, or any other centre. Let the Association have a well paid secretary, and if possible, provide its members with a copy of your Poor-law Intelligence weekly. A journal would be better, but would entail a higher subscription than 10s. 6d. Let there be a general meeting of members once a year in different parts of the country for the discussion of the proper measures to be taken for the advancement of the interests of the profession, and let a council be elected in some such way as I propose, so long as each member shall feel he has a direct interest in his representative, much more frequently for executive purposes.

By such an organisation would the whole body of the profession be induced to enrole themselves as members, and each exert himself, through his representative, for the benefit of all. The apparent apathy is due, I am persuaded, not to any want of interest in so important a matter, not to any indisposition to pay the small tax, but to the feeling that the entire control of the Irish Medical Association, as at present constituted, is in the hands of men who have no community of interest with the great mass of the Poor-law medical officers, *alias* the country practitioners of Ireland, and that individuals cannot promote their views except by going to the trouble and expense of attending an annual meeting in Dublin, where the poor country doctor would probably feel too small to express his opinions and too proud to confess his poverty.

For the present, Sir, I leave this matter to the consideration of your readers and the council of the Irish Medical Association. It is with no ill-feeling I have written about it, but rather in the possible hope that by drawing attention to its failings it might be made what it ought to be, the General Association of Medical Practitioners in Ireland. Trusting that my professional brethren will take the matter up, and not let it drop till they are united into one great body able to dictate its own terms, to withstand oppression, and to place medical men in a fitter social position than most of them at present occupy,

I am, &c.,

PHILADELPHUS.

WE have accepted our correspondent's letter, it being our principle to allow free expression to every one who writes honestly his convictions, although we may differ widely from his opinions. We are glad of the opportunity he affords us to say a word respecting the "Association." To take the criticisms of "Philadelphus" in their order, and first amongst them the charge that the "Association" does not embody more than one-third of the profession in Ireland, we are obliged to classify the profession from his point of view, and for our correspondent's

Digitized by Google

behoof Irish medical men may be divided into three classes—(*a*) the "big wigs" who have no time to devote to the affairs of other people, and not the remotest personal or pocket interest in the objects to which the "Association" is devoted. These are the gentlemen to whose presence on the Council "Philadelphus" objects, and we do not hesitate to say that they are amongst the most useful members of the organisation. They give their presence and their influence when it is asked for, and have more than once stood by the "Association" with their money when it was in straits; their relation to the "Association," moreover, gives it a political strength which it could not otherwise possibly have. They submit to be taxed every year for the advantage of their poorer brethren, and are never niggardly of either trouble or money for the furtherance of objects from which they themselves cannot derive a scintilla of benefit.

The second class of Irish practitioners (*b*) are those who are really in earnest in the work of amelioration with which the "Association" is engaged. Nine-tenths of them pay a subscription, which sometimes they can ill afford, and many of them help the execution of the I. M. A. with a much more valuable contribution than their money, viz., their advice and suggestions. As a sub-class of this class (whom we will call the "earnest men") we have a few (amongst whom we must frankly include our correspondent) who are strong in feeling favourable to the objects of the "Association," and even hyper-emphatic in their views and hyper-vigorous in action. These gentlemen are invaluable as counter-irritants, but they have one and all their own particular tuft of hay on their own particular horn, and they cannot see why the Council should not devote its whole soul to their grievance and proceed instantly to smash the Local Government Board, the Government and Parliament. Our chief regret is that the circumstances of their locality and of their business prevent these gentlemen from joining the Council (some of them it would appear do not even join the "Association"), when they would be able to express their views *ore suo*, and would speedily learn that fortresses are not won by using the crania of the assailants as battering-rams, and that no organisation can effect anything unless it moves constitutionally, reasonably, and patiently towards its purpose.

The third class of the Irish profession (*c*) are the drones of our order. They do not manifest their belief in any mutual organisation whatever, and, while quite ready to profit by anything that is done for the profession, are too selfish to contribute an iota to that result. They will neither offer a suggestion, answer a letter, pay a subscription, or read anything sent them, but they will grip every sixpennyworth of advantage which the labour of others procures for them, and will diversify that employment by grumbling incessantly and abusing their own profession all round. We regret to say the class is numerous, and its existence accounts, more or less, for the disproportion between what the members of the "Association" ought to be and what they are.

Nevertheless, the Irish Medical Association may claim to be a highly successful organisation, for we can assure our correspondent that it is a very gratifying success to secure even one-third of any class as co-operators in any organised work. The "Association" can show work and results achieved by downright hard labour and great perseverance, for which the whole profession in Ireland ought to be grateful. It was the author of medical superannuation, the principal instigator of medical registration, the chief agent in educating the country up to improvement in the salary of Irish poor-law medical officers, and procuring a revision of the fees to medical witnesses, and within the past two years has obtained for those officers a doubled vaccination fee and a change of law which must ultimately involve a great improvement in their position as sanitary officers. It has, meanwhile, exercised beneficial influence in and out of Parliament in favour of the Army Medical Department, the visiting physicians of lunatic asylums, the factory surgeons, and the prison and infirmary officers. If our correspondent had given himself the trouble to learn the extent and importance of these services to the profession he would, we feel certain, have abstained from his somewhat censorious criticism, and would be the first to offer his co-operation, hand, heart, and pocket, with the "Association."

As to his detailed objections, we need only say that the executive of the "Association" of which he complains because—he says—it is composed principally of "men who have but little direct interest in the trials and struggles of the dispensary doctor,"—is composed of 4 vice-presidents, of whom only one is a Dublin man; a chairman of council, who is himself a dispensary doctor; a council of 35 members, of whom no less than 26 were or are poor-law medical officers; and an executive committee of 8, of whom 6 are in the same service.

We don't know how much more representation of his class our correspondent would wish. As for his proposal for a peripatetic Association, which he bases on the ground of the inconvenience of going to Dublin, we may remind him that that inconvenience would be much greater to individual members the further the centre of meeting is removed from the centre of the country, and that inasmuch as the migratory meetings of the "Association" could offer no such attractions as those of the British Medical Association, they could result in nothing else but a calamitous failure.

We have made "Philadelphus" the text for a lengthened disquisition, but we are convinced that his *animus* is just that which would be of most value to the "Association," and we hope we may have succeeded in persuading him (and many of class *c*) to pay their subscriptions and give their hearty aid to an honest and zealous effort made for their benefit.

CLAREMORRIS UNION.

PROPOSED REDUCTION OF SALARIES.

MR. O'CONNOR moved—"That a reduction of 20 per cent. be made on the salaries of all the officers of this board."

Mr. Treston, D. V. C., proposed as an amendment that the salaries be not reduced. It would be departing from the broad and just principle adopted by all public bodies

Digitized by Google

of giving increased pay for long and faithful services. If the times became as bad as was expected all the house officers would have their duties greatly increased, but particularly the dispensary medical officers. It would be ungenerous and unwise to cripple the resources, render it less efficient, or cause to be disappointed a body of men who had always been faithful to their post of danger, and at a time too when they are likely to need their best energies. The doctors must feel keenly the depression of the times, not being able to get fees from the country people, and the salaries which they gave them were hardly sufficient to supply them with servants, horses, care, &c., to drive about the country at all hours of the day and night in aid of the sick and poor.

A lengthened and animated discussion ensued, after which a division was taken, when there voted :—For the amendment, 11; against, 5. The original motion was lost.

[We are pleased to see that there is at least one guardian in Ireland who can appreciate what is fair towards the dectors, as well as the ratepayers. Surely, if there be any class of officers more than another which is likely to suffer by the hard times, and to experience the pinch of want, that class is the medical officers. Those officials who receive fixed salaries are even better off during a season of depression, because they have the advantage of reduced prices, and enjoy and undiminished salary; but the medical officers at once feel the impecuniosity of the farmer or shopkeeper by the diminution of their fees. Where is the equity of compelling an impoverished medical man to pay the taxes of an impoverished tenant? This is what the reduction movement means.—Ed.]

TUAM UNION.

PROPOSED REDUCTION OF SALARIES.

Mr. O'Flaherty moved :—

"That the salaries of the several medical officers of the union be reduced, so much as the increase of fees resulting from the Vaccination Amendment Act of last session may exceed their original salaries and fees, and that all former resolutions shall be rescinded."

He remarked that a similar resolution had been adopted in Galway, and it would be a warning to the Legislature not to tax the over-taxed people of this country without consulting their wishes and in obedience to the manœuvring of a little lot of active medical M.P.'s. A more careless and slipshod measure than the same Vaccination Amendment Bill never came from the Parliamentary anvil. There was under it no protection against a doctor, clever at figure manipulation, committing frequent fraud, and by increasing the fees they were paying a premium for such cleverness. He did not say that the doctors did or would do so, but it was highly possible for them, and it was relying too much upon their honour to leave such matters very much in their own hands. He knew of an instance in a neighbouring union, with whose affairs he was conversant, where a doctor got £50 for vaccination, and speaking to an official authority, he was told that in the time specified, it was physically impossible for the doctor to earn it. The legislature was being shamefully operated upon by the medical men, and they are managing very successfully to increase their stipends year by year. He now proposed to limit the doctors' salaries to the standard of the past year. The doctors earned a good thing by registration, vaccination, and by that greatest mockery of recent acts—the Sanitary Act. What earthly use to that board was a consulting sanitary officer? or a sub-sanitary officer?

Mr. Kirwan seconded the resolution; after a while it would be all pay and no work in this blessed union. And the Sanita.y Act was a humbug.

The Clerk stated, in reply to Mr. Burke, that the amounts paid for vaccination during the past year were as follows :—

Dr. McDonnell, £13 17s.; Dr. Flood, £11 10s.; Dr. French, £5 4s.; Dr. Turner (No. 1), £12 15s.; and Dr. Turner (No. 2), £13 10s. In all about £57, all off the rates.

Mr. Gannon said that the resolution made the government a present of half the reductions that would be made in the salaries of the officers.

Mr. Nolan objected to the resolution, for he thought the sum 2s. allowed for vaccination was only sufficient for the many duties performed which were very onerous. The total amount is so small, £57 was not worth inquiring into. He opposed the resolution by a negative.

Mr. Burke seconded the amendment. He agreed against the impolicy of increasing the burdens on the rates, but he disagreed with the manner in which it is now sought to oppose it. If the medical officers were guilty of the practices suggested, the board would pass the resolution at once, and unanimously, and he cannot believe the members of so respectable and highly honourable a body would be lending themselves to fraudulent practices. The vaccination fees were also unfixed quantities varying from year to year. He also did not believe the the collective wisdom of the union board would be allowed to over-ride the collective wisdom of the Parliament of the nation. £56 on the valuation of the union is only the 1-6th of a penny.

Mr. O'Flaherty—The L. G. B. have actually agreed to the same resolution in Galway. You may remember I proposed a resolution calling our members' attention to this very Bill then passing the House, but none of the four took the slightest notice of it. Two of them are doctors (Messrs. Henry and Ward), and perhaps had sympathy.

A poll was taken :—For, 3; against, 7.

The resolution accordingly fell.

[We are pleased to observe that the better sense of the Tuam guardians prevailed over the stump rhetoric of Mr. O'Flaherty. This person, we understand is, or was, one of that favoured class who owes to an Act of Parliament a rank which the schoolmaster failed to give him. He is a *quondam* attorney, and *sequiter*, a gentleman, and, doubtless a very useful member of the board of guardians. "Suspect everyone," and "Set a thief to catch a thief," are excellent business mottoes even when applied by a board of guardians to its medical officers. Mr. O'Flaherty is a man of some distinction, having, in 1848, shown himself to be the owner of a loud tongue and a ready pair of heels when his political seat became rather hot for comfort. It would be a pity that he should lose the opportunity for getting up a little popular steam at the expense of the doctors, who know better than to trouble their heads about his oratorical effervescences. After all, his utterances can persuade no one and do no harm. What should any one of his trade know about falsified accounts or fraudulent charges? Pooh! Pooh! It is too ridiculous.—Ed.]

DROGHEDA UNION.

SCARLATINA.

Dr. Kelly observed that he had recently occasion to visit portion of that district in discharge of his duty as urban sanitary officer, and he met with no fewer than ten cases of scarlatina in four or five houses. From his observations, he had no doubt whatever that the occupants suffered from extreme poverty, and that filth abounded. This filth was, no doubt, a great agent in the propagation of the

Digitized by Google

disease, but after a while the observance of cleanliness would be enforced, and this danger removed. There was, however, another agency at work which the doctors had no power to prevent, and which greatly tended to the spread of the epidemic. He referred to the holding of wakes on persons who died of infectious diseases. The other day he went into a house where a child who had died of scarlatina was being waked. There was only one room in the house. Another child lay ill of the same disease, and fourteen or fifteen persons were round the corpse. It was needless to say that the spread of scarlatina was very much due to this practice; and in the burial of children too, who die from that malady, he observed that very thin coffins are used, mere shells in fact—and these were carried through the streets to the graveyard borne on the shoulders of children who, of course, came in direct contact with the disease and spread it from one to the other. He suggested that the relieving officer should be instructed to see that double coffins were used in such cases, or that lime or tar were placed inside.

Mr. Whitworth—Do you think the parents would allow that to be done?

Dr. Kelly—I would not ask them.

Mr. Mangan—If the law does not compel them to do such a thing you may rest assured that they won't do it.

Dr. Kelly—It is very improper to allow burials to take place as they at present do—the bodies not securely incased, and carried through the town by children. There is no more infecticus disease than scarlatina.

Mr. M'Kenna—I believe it is worse than small-pox.

Dr. Kelly—It is, far; and these poor people are not able to give their children sufficient nourishment when they become convalescent; they also allow them to run about on the cold floor on their bare feet, and the result almost invariably is that dropsy comes on and kills them.

Colonel Maguire—What remedy would you suggest?

Dr. Kelly—Why, to have the matter publicly known, so that people may use the proper safeguards.

Mr. Mangan—Would you not approve of disinfecting the houses?

Dr. Kelly—Yes, but some of the cabins I refer to are beyond disinfection. Nothing short of tumbling them down would be a compliance with the sanitary laws. I thought my own district was bad, but I find this is infinitely worse. There are forty or fifty houses in it not fit for human habitation.

The subject dropped.

MOUNTMELLICK DISPENSARY DISTRICT.

PAYMENT OF SUBSTITUTE.

The Clerk read the following letter:—

Local Government Board, Dublin,
28th October, 1879.

Sir,—The L. G. B. for Ireland have had before them the minutes of proceedings of the board of guardians of Mountmellick union on the 18th inst., and desire to express their sanction to the proposed payment of a sum of £14 2s. to Dr. Rice for acting as temporary substitute for Dr. Clarke, medical officer of the workhouse and of the Mountmellick district, during the absence through illness of the latter.—By order of the Board,

B. Banks, Sec.

The Clerk said he had since received a letter from Dr. Rice refusing to accept the £14 2s., and stating that if he were not paid the full amount, £16 4s., he would place the matter in the hands of his solicitor for collection.

Mr. A. Peacock—Dr. Rice has a perfect right to be paid the full amount; there was a guarantee given that he would be paid it.

Clerk—There was no guarantee given at this board.

Mr. J. Peacock—Was there a guarantee given at the dispensary?

Mr. A. Peacock—There was.

Mr. Gaze—I think Dr. Clarke would prefer to pay Dr. Rice the two guineas in dispute out of his own pocket.

Mr. Cobbe—The honour of the board was discharged when we offered all we agreed to pay him. I therefore propose that we don't offer him the cheque again.

Chairman (to Mr. Pattison)—You have discussed this matter now *ad nauseam*, and as there is no resolution before me, I will proceed with the other business.

GORT UNION.

GORT DISPENSARY DISTRICT.

At a meeting of the Gort Dispensary Committee, held on the 1st November instant, a letter was read from Dr. Nolan, medical officer, stating that owing to the pressure of private practice and other circumstances, he was obliged to retire from a portion of his public duties. He therefore begged to place in their hands his resignation of medical officer of the district, which he had held for nearly two-and-twenty years, and to convey to the Committee his sincere and grateful thanks for the unvarying kindness and courtesy he had always experienced from them.

The following resolution was unanimously adopted:—Resolved—"That we receive with much regret Dr. Nolan's resignation, and desire to place on record our marked sense of the skill and attention with which he has discharged for a lengthened period the onerous duties of medical officer of the district. We are much pleased to learn that the sick poor of this union will continue to have the advantage of his care in the workhouse hospital, which under his well-known ability and experience has been brought to its present high state of comfort and efficiency."

On the above proceedings being submitted to the Board of Guardians—"The Board desired to express their entire concurrence in the complimentary resolution passed by the Committee to Dr. Nolan."

SHOCKING CRUELTY BY A BONE-SETTER.

At the Boyle Petty Sessions, last week, a "bone-setter," named Mullany, was charged with being guilty of cruelty to animals under the following circumstances:—It appears a carter's horse slipped and sustained a fracture of the leg at the elbow. The defendant was sent for to attend the animal, and he proceeded to remedy a fracture of an elbow-joint by putting wooden splints on the horse's knee, drawing the skin through the slits, and driving iron spikes a few inches in length through the skin and flesh in order to secure the splints to the leg. The wounds thus occasioned festered, and suppurated matter flowed through them, and the poor horse, after enduring great agony for a few days, was shot. The defendant now said in excuse that he was in the habit of "fixing" cattle and horses for the last 35 years, and with great success. His solicitor described the defendant as a public benefactor, and said that so long as such men were to be had in the union it was a humbug to be bringing veterinary surgeons into the place and paying them salaries out of the rates. *The bench imposed a fine of five shillings.*

TO READERS.

The Editor will feel especially obliged by receiving copies of newspapers which contain any Poor-law or other intelligence of medical interest, in order that he may, if fit, republish it for the benefit of the readers of the *Medical Press*. Although twenty-one of the leading Irish newspapers are received at the Irish office, many things may escape notice which are deserving of attention. Newspapers should be marked, and addressed to Dr. Jacob, at the Dublin office of this paper.

ON SYPHILITIC URETHRITIS AND VAGINITIS.

By DR. CHARLES R. DRYSDALE,

Senior Physician to the Metropolitan Free Hospital.

THOSE persons who have for many years devoted much attention to minute points in the diagnosis of the so-called contagious diseases, must be well aware that during the last quarter of a century a number of dogmas which were held by former practitioners of the greatest experience, have been called in question, and apparently refuted. One of the chief points in the doctrine of the distinguished Ecole du Midi of 1838, of which M. Ricord was the leader, was the assertion, that there were two distinct venereal diseases, gonorrhœa and syphilis. Bassereau, again, made a further subdivision of the contagious diseases into syphilis, soft sores, and gonorrhœa. (*Aff. de la Peau*, Paris, 1852.) If we attend, however, to the opinions of some of the predecessors of these great modern writers, *e.g.*, Pearson, the distinguished surgeon to the London Lock Hospital, we find him writing thus: "We have seen so many cases of gonorrhœa communicating syphilis, as to leave very little doubt in our minds of this being the case. We have seen several instances of venereal symptoms following gonorrhœa; and where persons having gonorrhœa have communicated venereal symptoms." Mr. Henry Lee, commenting on this passage, adds (Lectures, p. 87), that the infection in these cases did not depend upon a chancre in the urethra, I think is shown by the extreme rarity with which such chancres exist; and with regard to the infecting form of chancre, I should say it is almost if not wholly unknown. Hunter opened the urethra in many cases where he supposed persons were suffering from a disease connected with syphilis, but never found any ulceration. The cases of chancre larvé cited by Ricord have been doubted to be chancres at all.

Swediaur had convinced himself from his own experience, that those who alleged that gonorrhœa and syphilis were always the effects of the same poison, and those who predicated the contrary, were both in error. He affirmed that he had proved to demonstration that the discharge of the canals, in either sex, at one time was due to the syphilitic poison, and at other times to some other irritant applied to the urethra in the male or to the vagina. He narrates several cases which go to prove that a discharge at one time may be syphilitic, and at other times be very different in its nature, adding, "It will easily be conceived of what importance this distinction is in practice, and when, on the other hand, we see practitioners treating all gonorrhœas as venereal (syphilitic) with mercurials; and, on the other, when by an ill-founded theory they suffer the syphilitic virus to be communicated, and the disorder propagated through whole families, without giving themselves any trouble as to the unfortunate results."

It seems, I think, worth while revising recent opinions on this subject, and examining whether Ricord was quite right when he said that gonorrhœa was *never* a symptom of syphilis; or whether John Hunter was not right in alleging that a urethral discharge might be inoculated so as to produce constitutional disease.

It must be noticed, in the first place, that the test made use of by M. Ricord, M. Vidal, and many others of the students of the Hôpital du Midi, namely, auto-inoculation of the patient with the secretions from gonorrhœa or syphilitic symptoms, has subsequently been found to be fallacious in its method. In 1856, our late respected and much-deplored president, Mr. Victor De Meric, in an essay which gained the Jacksonian prize at the College of Surgeons of England, pointed to the production of the specific pustule as *the* test of primary syphilitic sores. If this had been true, it would have followed that no secondary symptom of syphilis was ever contagious, and M. Ricord's experiments on anto-inoculation brought him for a time to this belief. He also repeatedly made auto-inoculations from the secretions in gonorrhœa, and found constantly negative results, from which he concluded, and his belief

Digitized by Google

is nearly universally held at this moment, that gonorrhœa was never a syphilitic symptom, or capable of infecting.

Everyone now knows that this very reasoning would convince an auto-inoculator that hard chancres are not contagious, since, unless irritated, they too are not inoculable on the patient on whom they are found. The soft sore is auto-inoculable *ad infinitum*, and was, therefore, considered by Ricord to be the parent of syphilis, a mistake which is now so entirely exploded, that many of us hold at this time that soft sores are *never* in any instance followed by syphilis, where these are unaccompanied by other lesions, although Mr. Jonathan Hutchinson and others would probably take exception to this. Everyone at present is convinced, and justly convinced, that *ordinary* cases of urethritis of the male are not syphilitic, by merely watching the natural history of the disease, as seen in hospital and private practice; but the next step to this, which is taken by the great majority, if not almost the entire mass of the profession, especially in France at the present time, in alleging that *no* urethritis which is not accompanied by some ulcer is contagious of syphilis, is taking far more for granted than can readily be admitted. In the female sex, persons who have had experience in the wards of female Lock Hospitals must, I think, have long doubted entirely the propriety of such a generalization, when considering the origin and consequences of vaginitis and uterine catarrh; but Mr. H. Lee has had the merit for many years of laying down similarly in the case of the male that there is a special kind of urethritis or urethral discharge which differs in some of its symptoms from ordinary gonorrhœa. Such discharge, he affirms, occurs not so very unfrequently as is supposed in male patients who are suffering from syphilitic secondary symptoms, and who yet have not exposed themselves to any fresh chance of contagion. Such discharge has been described by him as consisting of a greyish viscid secretion, often like thin oatmeal gruel. As it is not accompanied in most cases by any pain in micturition, it attracts very slight, if any, attention from the patient.

Now, it is very rare indeed, as far as I know, although I shall be quite prepared for any allegations to the contrary, to find an *indurated* sore in the male urethra, although of course, the syphilitic poison must often come in contact with its mucous membrane. When it does occur, it almost invariably seems to occur at no greater depth than some quarter of an inch from the orifice. The urethritis which ensues at the primary or secondary period of syphilis may persist for a long time, and, of course, is not auto-inoculable, except in those very rare cases mentioned by Dr. Morgan, of Dublin, in his experiments at the female Lock Hospital.

John Hunter's experiment in inoculating on himself the secretion from a man with gonorrhœa, would of itself serve to clear up the question as to whether gonorrhœal urethritis is ever contagious. In his own case, the inoculation was followed by a hard sore on the penis and specific symptoms, which lasted some three years.

As to vaginitis, having been for some years physician to a female Lock Hospital, I have learnt to be able easily to account for what used to puzzle me in former years. I allude to the fact, that gentlemen will come to the practitioner, complaining that they have contracted syphilis from a woman who was alleged to have no disease whatsoever. I have seen such cases, and will narrate one.

1. A gentleman, æt. 40, a widower, with a family of children, remained continent for some years, but at length had intercourse with a woman from whom he contracted a sore phagedænic in character. On my stating the nature of, his disease he said that the woman with whom he had relations was most anxious to be examined, as she was in perfect health, and could not in any way account for his disease. I examined this female patient and found not the slightest external mark of any disease, except a few enlarged glands in both groins. There was, however, a history of syphilis, dating back some years. On passing the speculum, there was seen to be some uterine catarrh, and an abrasion of the cervix uteri. The gentleman, who was an able professional man, and most solicitous about his health, assured me that this was the only possible source of infection, as he had had no intercourse with any other person since his wife's decease, and I believed him perfectly.

Such cases, I am sure, must have been seen by every practitioner who takes any accurate history of the disease as seen in practice; and my experience of syphilis in women shows me that a very frequent result of secondary syphilis in that sex is the occurrence of syphilitic vaginitis or uterine catarrh, symptoms which will supervene months after the patient has entered hospitals where, as in the case in the Rescue Society's excellent little home hospital, no possibility exists of any further contagion occurring.

2. A gentleman, some years ago, brought his wife to me, who was suffering from an universal rash of secondary syphilis. She had been married some six months, and was quite regular, that is, she was not pregnant. After questioning her for some time, I informed the husband that he had infected his wife with syphilis. He was deeply grieved, and much surprised. "I have not had any syphilitic symptoms," he said, "for some four years, when I had been treated for the disease for two years, and believed that it was entirely eradicated." On examination of this gentleman I noticed a slight palmar psoriasis and eruption on the scrotum; but he admitted that, since his marriage, he had noticed a slight discharge from the urethra, which, however, as it gave him no uneasiness, he had looked upon as of no importance. Here, then, it seems to me, was a clear infection of a wife by her husband without pregnancy, four years or so after the appearance of the primary sore, and through means of a syphilitic urethritis.

Such cases as these are of importance in medico-legal practice, and I have been witness in a case in the Divorce Court where there has been a doubt in my mind whether the husband, who clearly infected his own pregnant wife, had not done so in such a manner, *i.e.*, by means of an infection obtained by him many years before marriage. I suspect that many unfortunate husbands have had their characters as honourable and faithful partners needlessly and unfairly blackened and their reputation destroyed by the existence of some such urethral discharge supervening soon after marriage, and which proved the vehicle of the contagion of the disease, which was otherwise latent in themselves. On the other hand, when a husband who supposes himself perfectly cured of syphilis, sees his wife infected shortly after marriage, he is apt to suppose that she must have been breaking her part of the contract, and hence may cruelly maltreat a most innocent woman.

3. Mr. H. Lee mentions a case of a gentleman who had syphilis four years previous to his marriage, and in whom some slight eruption remained, and who infected his wife in this way. The relations of the lady, acting on a medical opinion, accused the husband of unfaithfulness *posterior* to marriage. In another case a gentleman, with secondary symptoms, married, and soon his wife had a sore, which stained her linen, and enlarged inguinal glands, with vaginal discharge. This latter was clearly syphilitic in character, and was not communicated to her husband.

Dr. Bumpstead, of New York, in his work on Venereal Diseases, written in 1870, agrees that urethral discharges in the male are sometimes due to changes in the mucous membrane lining the canal, induced by constitutional infection. He had in several instances noted a muco-purulent discharge, coinciding with the first outbreak or a relapse of secondary symptoms. Bassereau (*Affections S. de la Peau*, p. 356) speaks of similar cases. Bumpstead remarks what is evident, that there is no more frequent seat of early secondary symptoms than the mucous membranes in general, and in the cases referred to. Changes probably take place in the urethral walls similar to the erythema, mucous patches, and superficial ulcerations found within the nasal and buccal cavities. He admits that such cases are rare, and thinks that they can only be distinguished from ordinary gonorrhœa from a knowledge of the history and accompanying symptoms on the patient

Digitized by Google

Since the secretions of secondary disease are commonly contagious, the discharge in these cases is also doubtless contagious upon a healthy person.

The late lamented Dr. Morgan, of Dublin, it will be remembered, read at the Medical Society of London some years ago a most important and intesesting paper on the occasional auto-inoculation of syphilitic women with the product of the secretions from the vagina and cervix uteri. In one case (381) where a young woman was suffering from syphilis, she was inoculated from the secretion of the vagina of another patient with syphilis, who was suffering from vaginitis; and a sore, of which Dr. Morgan showed drawings, appeared. In another case, the vaginal secretion of a patient who had been in hospital a month with syphilitic symptoms was inoculated on herself, and produced a pustule; and in a third case, a syphilitic girl, aged 8 years, was inoculated from the vaginal discharge of another syphilitic patient, and a pustule followed. In these three cases there can be little doubt that had the vaginal mucus from the syphilitic women been inoculated on non-syphilitic patients they would all have had syphilis inoculated.

At that meeting, when Dr. Morgan's paper was read, I stated that I had entirely failed to verify his results, except in one case, out of some fifty experiments, where the discharge from the vagina of a young syphilitic woman was inoculated on herself, and produced a pustule without incubation ("Transactions of Medical Society)." Since then my similar experiments have all failed.

John Hunter observes, in his work on the Venereal Disease, that infection of a patient's system might be effected by gonorrhœa quite independently of chancres, and that the matter of a gonorrhœa will produce either a gonorrhœa, a chancre, or syphilis. He adds that many gonorrhœas are seen which begin without any appearance of inflammation, which are not easily distinguishable from non-venereal or non-syphilitic gonorrhœa, as there are a number of symptoms common to all diseases of the urethra, which makes it difficult to distinguish the few that are syphilitic in origin.

That gonorrhœa should be the primary symptom of syphilis in some cases without any ulceration appearing, seems an impossibility to myself and to most writers; but it is well known that when inoculations have been made of syphilitic secretions on non-syphilitic persons by Wallace, Rinecker, and Lindwurm, the primary disease may appear as a papule in some cases, without any suppuration at all or any important ulceration, and no scar being left behind. Clinical experience, too, tells us that syphilis often enters the system with so little irritation at the spot when inoculated, as not to be remarked by the patient, especially the female.

(To be continued.)

PAUPERISM AND DRINK, WITH SOME REMARKS ON THE MEDICINAL VALUE OF ALCOHOLIC BEVERAGES AND THE MORTALITY FROM ALCOHOL IN WORKHOUSES.

By THOMAS M. DOLAN, F.R.C.S.Ed., L.R.C.P.E., &c.,
Medical Officer Halifax Union Infirmaries.

(Concluded from page 433.)

III.

The mortality in workhouse hospitals is another subject requiring consideration; and in the *Lancet* of 1877, vol. ii., p. 334, may be found a letter from me with some striking statistics in reference to my death-rate.

In 1869, when first appointed Medical Officer to the Halifax Workhouse, my daily average number of patients was about 70 to 80, and my infirmaries were somewhat after the old workhouse type.

In 1870 the guardians, with a true policy of enlightenment and progress, and with strict regard to true economy, erected new hospitals, on the pavilion system, with accommodation for 220 patients. The admissions have gradually and steadily swelled, the official daily number of sick being as high as 202, besides having on an average 40 male and 50 female imbeciles. But though the number of sick has increased, the death-rate has not proportionately increased, as may be seen from table C., taken from the workhouse register of deaths. I need not enter on the possible explanation of the stationary ratio of deaths, though I may add that the consumption of wine and spirits has not had any effect in relation to it.

In table B I have arranged the ages, of the patients who have died, in groups, from which it may be seen that paupers live to a tolerably good age, and though intemperance does lead to a certain proportion of pauperism, yet it does not seem to have such an injurious effect on longevity.

The table speaks for itself, and may be compared with the statistics (*a*) of Dr. Webster, Medical Officer of St. George's Union Infirmary.

From his returns I find that from Lady Day, 1878, to Lady Day, 1879, there had been 313 deaths; and of this number 105 were over 70 years of age, 63 were between 60 and 70, the average age at death being 58. Still further inquiry might be made as to the average age, at death, of of the non-pauper class who are engaged in similar avocations to those usually followed by the class found in workhouses. A comparison of the ages of total abstainers of a similar class might thus be made.

TABLE B.

Number of Deaths in Halifax Union Infirmary from Sept. 24, 1873, to Aug. 26, 1879, with ages in groups.

Age.	Deaths.	Age.	Deaths.
10 and under ...	70	60 ,, 70	**169**
10 to 20	9	70 ,, 80	**140**
20 ,, 30	42	80 upwards ...	54
30 ,, 40	80		
40 ,, 50	89	Total number	778
50 ,, 60	**125**		

TABLE C.

Annual Number of Deaths since 1868, *taken from letter to the "Lancet," on Hospital Mortality* Vol. II., 1877, p. 334.

Year.	No.	Year.	No.
1868	128	1873	124
1869	119	1874	125
1870	132	1875	111
1871	110	1876	110
1872	130		

Statistics and figures are capable, I am well aware, of different interpretations, and I submit mine to the unbiased minds both of temperance and teetotal inquirers.

The problem placed before the medical officer of a workhouse is a very simple one; given a patient suffering from any disease, to restore him to health as soon as possible, or to prolong his life as far as possible, and to use such means for this purpose as his scientific and honest convictions suggest. The cause of the patient's disease should not affect the medical officer's decision; because a man has, through inherited disease perhaps, fallen into the debased habit of intemperance, he should not be, when sick, punished. If a medical officer of a workhouse were allowed to inquire into the cause of each patient's pauperism, and to act upon it, he might refuse to attend, unmarried pregnant woman, or another unfortunate class, sufferers from gonorrhœa and syphilis. If it were clearly established that alcohol increased our workhouse mortality, and that its employment, *as a medicine*, encouraged habits of pauperism, then there would be some reason for its total abolishment.

On the evidence we have at present, I submit that this is not proved. The scientific administration of stimulants is justified until a substitute for alcohol is provided.

(*a*) Dr. Webster's statistics are reported by Dr. Orme Dudfield. Full particulars on this point will be found in *Med. Press and Circular*, October 1st, 1879, in an article called "Workhouse Hospital Statistics on the Alcohol Question."

Digitized by Google

What I conceive to be most desirable, is the establishment of a scientific law to guide the administration of alcohol, for at present there can be no doubt it largely depends on the individual opinion and feelings of the medical officer. The attention of some of our scientific investigators might be usefully directed to the framing of such a code.

If patients could be cured without alcohol it would be so much the better, for there is nothing to tie the workhouse medical officer to the employment of this drug, but we want fuller and more scientific data before this can be accepted.

In the *British Medical Journal*, Aug. 30th, 1879, there is a very impartial leading article on the alcohol question, and the following suggestive paragraph cannot fail to be interesting to members of boards of guardians, as it opens out another problem. The editor says:

"Is there any economy effected in maintenance by disallowing stimulants? There do not seem to be precise data for answering this question. The only satisfactory reply would be a careful and laborious comparison, one with another, of the cost of maintaining patients, as far as possible similar and similarly situated, with and without the administration of alcohol. This comparison would have to take account of age, sex, disease and its duration, former mode of life, cost of maintenance per diem in hospital (it being admitted that patients on a non-alcoholic diet sometimes consume more food than those to whom beer is allowed); and, finally, the length of time spent in hospital, with a deduction for work, if any, done upon an alcoholic or non-alcoholic diet. Such an investigation would require skill, care, and time, but would not fail to be interesting if well done."

The alcohol question seems capable of indefinite expansion, as it may be considered from so many different points of view.

ON OBLIQUE LINEAR SCARIFICATION OF THE SKIN IN THE TREATMENT OF PORT-WINE MARK.

By BALMANNO SQUIRE, M.B. Lond.,
Surgeon to the British Hospital for Diseases of the Skin.

The performance of (vertical) multiple linear scarification as a remedy in some diseases and malformations of the skin as first proposed by myself, has now, for some two or three years, become commonly practised, but it has been found, both by myself and others, to be a more or less tedious process, more especially in relation to that otherwise invincible condition known as port-wine mark.

The "obliteration of port-wine mark without scar" is a problem which still demands a somewhat easier solution than has yet been found for it, and it is probable that in *oblique* scarification this end has been already arrived at.

The process of *vertical* scarification cuts off definitively all lateral supply of blood to the cavernous vascular structure of which the skin affected with port-wine mark mainly consists, but it does not cut off the abnormal supply of blood from *below*, namely, from the subcutaneous vascular network. Hence the frequent repetition of linear scarification which has hitherto been required, in order effectually to obliterate the port-wine mark. However, by means of oblique scarification the cure of any definite portion of a port-wine mark may be easily accomplished in only two sittings, and this fact is readily intelligible on the hypothesis that, in this way (after duly reversing the incisions in the manner to be mentioned), the supply of blood to the over vascular skin is finally cut off in *every* direction, except, indeed, by means of those limited channels which subsequently become re-established, and which serve eventually only for the due nutrition of the tissue operated on.

The satisfactory result which is thus obtainable is effected equally as in the case of vertical scarification without the production of any scar.

It remains for me only to describe the few details of the improved process.

At the first operation (performed after freezing the skin with the ether spray), the skin is cut by means of a scalpel rapidly into a series of minute squares, but the instrument, instead of entering the skin perpendicularly, enters it obliquely, that is to say, at an angle of 45° with the surface, so as to divide the skin, not into a series of vertical slices at each of the two crossed operations, but into a series of slanting flaps.

The second operation is precisely the same as the first, only that the slants are respectively the opposite of the slants practised on the the first occasion.

Bleeding is almost absolutely prevented by exercising effective pressure on the surface operated on for say about ten minutes continuously.

I am now engaged in devising the construction of an instrument with many blades for the prompt performance of this operation. It is an instrument similar in many respects to my (*vertical*) multiple linear scarifier, which perhaps explains itself sufficiently by its name.

ON OTHÆMATOMA, OR SANGUINEOUS TUMOUR OF THE AURICLE.

By RINGROSE ATKINS, M.A., M.D.,
Resident Medical Superintendent, District Lunatic Asylum, Waterford.

Of the various physical lesions, which accompany or complicate the course of cerebro-mental disease, the peculiar affection of the auricle, which has been variously termed "Othæmatoma," "Hæmatoma Auris," or "Sanguineous Tumour of the Auricle," is, at least from the pathological standpoint, perhaps one of the most curious and interesting.

About the year 1850, Franz Fischer directed attention to two forms of disease which affect the ear amongst those suffering from insanity, namely, "serous œdema," and "sanguineous tumours," the former appearing as a painless swelling, frequently bi-lateral, without any abnormal colour, and disappearing as rapidly as it became developed; the latter, on the contrary, were more frequently unilateral, painful, of a peculiar colour, and of longer duration, while they rapidly filled after evacuation of their contents, finally leaving permanent deformity of the organ. These tumours, he adds, have no preference for any one form of mental alienation, they never occur from traumatic causes, but are the result of passive hæmorrhages, or active effusions, the causes of which must be sought for in pathological states of the central organs of the nervous system. Marcé (*Annales Medico Psychologiques*, 1859) states that these tumours are often double and develop equally on both sides, that they co-exist with other inflammatory troubles, and partial apoplexies; they are not influenced by any treatment, and usually remain for about four months, and that the effusion is due to an alteration in the blood, which predisposes to hæmorrhages. M. Foville (*An. Med. Psych.*, 1859) states that the seat of the sanguineous effusion is localised beneath the hypochondrium, which has become detached from the cartilage of the auricle; he regarded these tumours as common amongst men, very rare amongst women, occurring independently of the character of the mental derangement, and, save in very rare instances, only in incurable cases, sometimes one ear being attacked, sometimes both, but in the latter case, the two tumours not appearing coincidently, they invariably terminated in induration, and shrivelling of the auricle. Foville further noted that there is an analogy in the condition of the side of the head and neck, in patients suffering from sanguineous tumours, and the effects which follow section of the cervical sympathetic or injury to the superior cervical ganglion in animals. Many of the points indicated by

Digitized by Google

the above-quoted authors have now been confirmed by the researches of more recent observers. Although several isolated cases are on record where auricular hæmatoma occurred in persons mentally unaffected (Duplay, Lennox Browne), yet as a rule the affection is wholly confined to those labouring under the various forms of psychical disturbance. The sanguineous effusion invariably occurs, as Foville has stated, between the perichondrium and the cartilage; the former becoming separated from the latter to a greater or less extent, thus localising the size of the resultant tumour, and it resembles both in its formation and course similar effusions occurring elsewhere. The blood cyst which thus becomes developed may extend over the entire concavity of the organ, filling it up with a smooth ovoid swelling which entirely obliterates the various ridges and hollows, or it may be more confined, occupying only the hollow of the concha, leaving the other portions free; or, again, the concavity of the antihelix may be the site of the effusion, when the tumour is of a more irregular outline and less defined; in any case the lobule is never involved, the tumour gradually disappearing above it. Othæmatomæ form with varying rapidity, in some cases appearing in one night, while in others the swelling first shows itself suddenly, and then develops gradually, some three, four, or more weeks elapsing before it attains its maximum size. The tumour during its formation is generally quite painless, the patient permitting its manipulation without any apparent discomfort, the surface assumes a reddish-blue colour, sometimes amounting to lividity, and occasionally, especially in the earlier stages, there is some slight increase in temperature; generally, however, the tumour appears, develops, and recedes, without any signs of inflammation. In some instances, where the distension is considerable, slight cracks may appear on the surface, through which oozes a sero-sanguineous fluid, indicating a tendency to rupture; if the contents be evacuated at this time they are found to consist of fluid blood and a milky serum. These tumours cause deafness, varying in degree according to their position and size. If the concha be the site of the tumour, the meatus will be almost completely blocked up, sound then being considerably dulled; while if the meatus is not involved in the swelling, there will naturally be little or no interference with the auditory powers. Until the tumour has attained its maximum size, it is in the acute or *primary* stage; having reached this, it then begins to gradually dwindle, the skin first looses the tense glazed appearance, and becomes wrinkled, dimpling, and puckering follow, and by degrees the tumour entirely disappears, finally leaving the ear crumpled and deformed, the degree of deformity depending, I believe, on the size and duration of the tumour. This crumpling and shrivelling is characteristic of the affection, and constitutes the *secondary stage;* it is brought about by the unequal contraction of the cyst wall, which has become adherent to the perichondrium and cartilage, and which, as the fluid blood becomes reabsorbed, contracts on itself, throwing the surface into folds and twists, which sometimes assume the most grotesque and bizarre appearance, and occasionally leave the entire auricle a shapeless mass, which henceforth becomes the permanent remanet of the affection. Regarding the origin of othæmatoma, many opposing views have been advanced. Some observers consider that they can always be traced to traumatic causes, being either the result of direct injury to the ear by violence, or produced by pressure of the head against the pillow. Were they due to violence inflicted on the ear, how many cases would come under observation every day! The ear of the schoolboy is frequently the recipient of directly applied force, and yet hæmatoma never appears as the result; further, no diminution has been noted in the frequency of their occurrence since the humane treatment of the insane has become universal, while if a hard pillow were to produce the vascular effusion, the number of cases would necessarily be multiplied many times, and would not affect both ears simultaneously, as they are found to do. I think there can be no doubt now that othæmatoma are really due to pathological causes, connected with the cerebral disturbance which gives rise to the mental derangement.

From the passive character of the effusion, its painlessness and non-inflammatory appearance, and course, as well as from the fact, as has been recorded by Foville and Lennox Browne, that it is often accompanied by other indications of vaso-motor disturbance, it seems most probable that the effusion is due to some change in the nervous apparatus governing the vascular supply to the neck, allowing of a dilatation and passive exudation of their contents in the particular region involved. M. Henri Bonnet, speaking of othæmatoma occurring in the course of general paralysis, says that these tumours are really "congestive apoplexies," produced by the gradual degeneration of the sympathetic nerves, which gives rise to a turgescence of the vessels of the ear, and as a result limited apoplexies are there formed. He adds, that it is the pathological repetition of the experimental section of the nerve above the superior cervical ganglion, a view already advanced by Foville, and now held by Robertson, Lennox Browne, and others who have written on the subject. As further evidence of the dilated condition of the vessels in this region, may be cited the recent observations on the distended, and even aneurismal condition of the internal carotid artery, which has been found in many instances in the bodies of individuals dying insane. Marcé, whom I have already quoted, believed the effusion to be due to some blood dyscrasia, while Virchow looks upon it as the result of local changes, "chondromatic softening." The blood, when once it has been effused beneath the perichondrium, undergoes sequential changes identical with those which occur in similar extravasations formed elsewhere. The fluid portion is slowly absorbed, a cyst wall forms, and the contents of the latter gradually becoming inspissated, appear on section as a tough fleshy-looking mass, presenting all the characters of organising blood clot; as this formation advances in age, connective tissue is developed, which contracts irregularly, drawing the cyst wall, which is now adherent to the skin and perichondrium, with it, and so producing the deformity of the ear; portions of this connective tissue finally become transformed into cartilage, and in cases of very long standing even into true bone. A microscope section in the advanced secondary stage generally presents cartilage, connective tissue, and islets of adipose cells in varying proportion. Othæmatoma, as had already been pointed out by the observers whom I have quoted above, does not solely affect any one form of cerebro-mental disturbance; the sanguinous effusion most frequently takes place where the mental excitement runs high for any lengthened period, indicating excessive hyperæmia, be that excitement maniacal or melancholic in its character. It is without doubt most frequently found in general paretic insanity, yet that it occurs extensively in other forms of the disorder, is evidenced by the fact that numbers of cases are seen in the large asylums in this country where general paralysis is all but absent. Epileptic insanity with acute excitement comes next on the list, while chronic maniacs, and those affected with acute and even active melancholia, also afford their quota of cases. It is very rare to see a sanguinous tumour in the primary stage in a case of secondary dementia (except in the paralytic form), but of course the shrivelled and crumpled ear characteristic of the secondary stage is often met with in chronic dements, as the physical remanet of acute disease long since passed away. Othæmatoma most frequently affects only one ear at the same time; in a proportion of cases, however, it occurs bilaterally, especially in general paresis. An analysis of a number of cases shows that when forming unilaterally, the left ear is oftener the site of the tumour than the right; its occurrence is, generally speaking, a most unfavourable complication from a prognostic point of view. As regards recovery from the mental derangement, my experience, however, has led

Digitized by Google

me to believe that it cannot be looked upon as an indication of a hopelessly incurable case, as some would have it to be. I have seen many patients leave the asylum recovered, whose ears bore the mark of former tumours, either of recent or more or less distant occurrence. As regards the treatment of this affection in the earlier stages, painting the surface with vesicating collodion has, in several recorded instances, been attended with success; the tumour receding leaving little or no deformity. When once, however, the swelling has become fully developed, surgical measures are the only means that can be had recourse to with any prospect of a successful issue. Evacuation of the contents has been recommended by Gruber, followed with compression of the cyst, so as to bring about uniform adhesion of the walls and equable contraction, and thus counteract the tendency to deformity. The proneness of the sac to refill, however, renders the successful attainment of this result very uncertain; and, further, if free incision be made, there is the danger of suppuration taking place in the renewed contents, and thus adding to the complication, which from the debilitated condition of the patient may run on to necrosis of the auricle. In addition, the mental condition of the sufferers generally renders effective compression very difficult of maintenance. In certain special instances, where other points were favourable, aspiration of the contents might be had recourse to, and subsequent compression, which would diminish the chances of suppuration, should the measure be unsuccessful in bringing about a rapid adhesion of the cyst walls.

CASE II.—*Ribbon Stricture.*—P. S., æt. 50, admitted to Co. Louth Infirmary on August 28, 1878; on examination with a wax bougie, a ribbon stricture was detected, situated 4 inches from the meatus. A gleet had existed for ten months previously. No urine had been voided for twenty-four hours.

The patient was placed in a reclining bath at 100° F., for 15 minutes: 20 drops of tr. opii were administered. An unsuccessful attempt was made to introduce a catheter into the bladder; with considerable difficulty a No. 1 French filiform bougie was passed; at the end of two hours a No. 2 was passed. On its withdrawal, at the expiration of two hours, about 4 pints of urine was with considerable difficulty voided. The bougie was again introduced and fastened in.

August 29th.—On removing the bougie this morning, the urine escaped; a No. 2 gum elastic catheter was fastened in. The stricture was, day by day, dilated, till a No. 8 could be passed readily, when the patient left the hospital (Sept. 12), with instructions to return in four or five days to have an instrument passed.

Sept. 30th.—I was sent for hurriedly to-day to see the man at his own house in the country, and found him as follows:—Temperature very high, pulse 140, tongue foul and dry, in great pain; the bladder enormously distended—no water had passed for two days; a large abscess pointing in the perineum. He stated that for the last week the stream had gradually got smaller and smaller, until finally, he could only squeeze out a drop at a time.

I attempted to pass a catheter, but failed; I succeeded in getting a No. 1 French filiform bougie through the stricture. The patient was placed in the lithotomy position, and the abscess in the perineum laid open in the median line; about 3 ounces of most fœtid pus escaped; the penis was then firmly held, while the incision was prolonged upwards for about ¾ of an inch; this was carried deeply down at the superior limit, and the urethra opened about ¼ of an inch from the prostatic end of the stricture. A catheter was carried into the bladder on a director and the urine evacuated. The silver director was then manœuvred through the stricture, being guided by the bougie, and the entire extent laid open; a gum elastic catheter (No. 4) was then passed into the bladder, the edges of the skin wound being united by silver sutures; a small drainage-tube was left in the perineal portion and carbolic dressing applied. A linseed-meal poultice over all. Eighteen drops of Battley's solution were ordered, milk and lime water *ad lib.*

Oct. 1st.—The dressings contained only a little sanguineous matter; temperature normal; no pain.

5th.—The wound has united along its entire extent, except where the drainage tube was in position. This was removed to-day, no dressings being required. The patient was put on a generous diet, and cit. ferri et quiniæ ordered. From this date the patient made an uninterrupted recovery. The urethra was dilated up to No. 8, and the stricture has not subsequently shown the least tendency to contract. The operation in this case was a modification of Cock's, which I think the most radical cure for such contractile strictures.

Dr. SQUIRE on

THE ACTION OF SALICINE AND SALICYLIC ACID IN ACUTE RHEUMATISM.

He commenced by some preliminary remarks on the value of rest as a factor in the treatment of acute rheumatism. Of patients so attacked not less than two-thirds of the whole number have heart complications, and fully one-half are permanently injured. No remedy given during the attack can prevent the heart complications. The alkaline treatment, if pushed, aggravates the subsequent anæmia. Of all remedies to check the fever, as cold bathing, digitalis, and iron, none are so satisfactory as the salicylate of soda. Cases were related where iron was given with some success, but then sedatives were also required to allay the pain. Cases treated by salicylate of soda did not require sedatives, as the pain was quickly relieved by this drug. The presence of the acid in the urine can soon be detected. Salicine is not a new remedy, but was used for the treatment of ague as far back as 1830. Its chief therapeutic action lies in its power to check fermentation. In acute rheumatism repeated doses are required. The objections to its use are singing in the ears and neuralgia. A healthy man could take forty grains of the acid or fifty grains of the salt; but if this dose were exceeded toxic symptoms manifested themselves. It was not desirable to give ammonia with the salt. Dr. Squire then spoke of some other diseases in which the drug is useful. He regarded the salt as a very convenient form in which to administer the acid, as by this form the irritating action of the free acid is avoided. Five grains of the salt represent exactly four grains of the acid.

Mr. HENRY POWER said that he had found aconite, colchicum, and quinine so useful in rheumatic affections of the eye that he was not inclined to give them up. The local application of solutions of nitrate of potash to the inflamed joints often was of great use. He had seen benefit arise from salicylate of soda in cases of rheumatic disease of the eye.

Digitized by Google

The PRESIDENT said the drug had proved valuable in his hands.

Mr. PYE said that he took thirty grains of salicylate of soda for six days without any effect.

Mr. STEVENS said that he found benefit from resort to the alkaline bath, and he inquired if salicylate of soda could be administered to the aged.

Mr. MASON said he found the drug valuable in cases relieved by cold applications.

Mr. MORRIS mentioned a case of gouty eczema which was relieved after a few doses of salicylate of soda.

Mr. GEO. FIELD asked if the author of the paper had ever found the drug dangerous, as he had been assured on good authority that a fatal issue had followed its use in several cases.

Dr. BIRDEN said he could corroborate the remarks of the last speaker, as he knew of two cases of death after its use. He also thought it tended to produce delirium.

Dr. CRIPPS LAWRENCE said he had found the drug serviceable; after which

Dr. SQUIRE replied, and the meeting adjourned.

Erratum.—In the discussion upon Dr. Hughlings-Jackson's paper on "Intra-cranial Syphilis," at the last meeting of the Society, Dr. Broadbent's remarks were unfortunately omitted.

Dr. BROADBENT said that sometimes it was very difficult to extract a history of syphilis, and one medical man even denied it for long. The difficulty was much increased in the case or women. Very frequently the stage when headache was the leading symptom had been passed before the patients are seen. A prolonged course of mercury was the best plan of treatment to adopt.

which he had removed from a girl, æt. 13, by rapid dilatation of the urethra, and crushing the stone. Before it was crushed it measured about an inch in length, and half an inch in breadth. A notable point in the case was the rapid recovery of power over the bladder. The girl was able to retain her water at the end of 48 hours, and made a most favourable recovery.

CYSTIC DEGENERATION OF THE KIDNEY.

The Pathological Committee brought forward their report upon a cystic tumour taken from the abdomen of a newly-born infant, which only lived one and a-half hours after its birth. The tumour was submitted to the previous meeting by Mr. Edward Skinner, and referred to the Committee for examination. The notes, as related by Mr. Skinner, stated that the tumour had been found in the abdomen a little to the left side, and just below the stomach. That it had been attached by peritoneum, vessels, &c., on to the small intestine and mesentery. There was only one kidney present, the left being absent. The other organs of the body were all healthy. The Committee now reported that the tumour measured three and three-quarter inches in length, and two and a-half inches in width, and consisted almost entirely of cysts, one large cyst occupying half the mass, and half a dozen smaller ones. At one point there was a depression, into which dipped a cord. This cord was found to be partially pervious, and on being traced upwards, it was found to be divided into five or six branches, which spread and dilated as they approached the cysts. No communications were discovered between these branches and the cysts; a little fluid escaped as the cord was cut. The large cysts contained a quantity of clear, straw-coloured fluid. The Committee came to the conclusion that the cord-like process is a ureter, and that the cystic mass represents a kidney, arrested in its development, with subsequent cystic growth.

The SECRETARY (Mr. Snell) communicated a case of

ECTROPION TREATED BY MEANS OF A NASO-BUCCAL FLAP, AND OTHER CASES.

The first case was one in which complete eversion of the left upper eye-lid in a lad had resulted (the ciliary margin of the latter being drawn up to the eyebrow) from extensive facial burns. The condition of the skin—being so much scarred with cicatrices—on the forehead and temple, &c., prevented a flap being taken from the usual localities. The case was therefore treated on a plan adopted by Noyes, of New York, by taking a flap from the side of the nose and cheek. The transplanted portion thus obtained readily filled the large gap which resulted after the lid by dissection had been replaced in its proper position. The palpebral fissure was also shortened by removing integument at the outer commissure and joining the edges together. Other details were mentioned. In the end the lad obtained a good and useful eyelid. Photographs of the patient before and after operation were exhibited. Three other cases of ectropion of the lower lid, treated by the operations more in vogue, were related also, and photographs shown.

POLYMORPHISM OF FEVER POISONS.

Dr. INKSTER read an interesting paper, taking the above as his text. He argued that there was much to be said for the idea that one primary fever poison may, influenced by surrounding circumstances, social, moral, atmospheric, or telluric, exhibit itself in a variety of forms. That, according to circumstances, we may have the poison of typhoid fever in the one instance showing itself as yellow fever or typhus under different surroundings. He seemed to be of opinion that Darwin's theory of evolution may prove applicable to fever poisons.

In the discussion that ensued the President and Drs. Law, Banham, Pye-Smith, Keeling, and Martin took part.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE quarterly meeting of the Association was held November 13th in the rooms of the Medico-Chirurgical Society of London, Dr. LUSK, M.P., President of the Association, in the chair.

Dr. WILKIE BURMAN read a paper on "The Separate Care and Treatment of Acute and Cursable Cases in Asylums, with Propotals and Suggestions for a Detached Hospital for special purposes in connection with very large Public Lunatic Asylums."

An interesting discussion followed, and the further consideration of the subject was adjourned till the next meeting.

Dr. HACK TUKE exhibited a

BRAIN PRESERVED BY GIACOMINI'S METHOD.

PHARMACEUTICAL SOCIETY OF IRELAND.

MEETING OF THE COUNCIL, NOVEMBER 5.

Resolved—"That the School of Chemistry in connection with the Working Men's Institute, Belfast, be one of the schools from which this Society will accept certificates of Practical Chemistry.

Mr. Holmes being absent, his motion by his request was proposed by Mr. Payne as follows:—

"That the Preliminary, Entrance, or Matriculation examinations of the following bodies be accepted by the Pharmaceutical Society of Ireland, in lieu of the Preliminary examination as at present required, viz., Trinity College, the Queen's Colleges, the College of Surgeons, and the Apothecaries' Hall of Ireland. Candidate to pay entrance fee as heretofore."

Motion was not seconded, and was withdrawn.

Proposed—"That the Preliminary or Matriculation examination of the College of Surgeons, or such other examination as is accepted by the General Medical Council as equivalent to it, and the Preliminary examination of the Pharmaceutical Society of Great Britain, be accepted instead of the Preliminary examination of this Society; such examination to be passed at least two years before the candidate presents himself for the licence of this Society. The usual fee of two guineas to be paid."

Amendment proposed—"That the Preliminary examination of the Pharmaceutical Society of Great Britain be omitted,

Digitized by Google

until the Council of that Society be asked if they will accept the certificates of candidates who have passed the Preliminary examination of the Irish Pharmaceutical Society, in lieu of their own Preliminary."

This amendment was lost, on a division, and the original motion was then put and carried.

Resolved—"That the Chief Secretary for Ireland be requested to receive a deputation, who shall be empowered to explain the views of the Council with reference to the proposed amendments in the Pharmacy Act, and the working of the Poisons Act generally in Ireland."

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 26, 1879.

CROUP AND DIPHTHERIA.

MOST of our readers have probably seen, in our impressions of October 29th and November 5th, a paper on Croup, by Dr. W. H. Day, a frequent contributor to our journal on the diseases of children. We are of opinion with the writer that croup is, both pathologically and clinically, a distinct disease from diphtheria.

Dr. Day divides croup into two varieties: 1. *The catarrhal, or mucous.* 2. *The fibrinous, croupous, or membranous croup.* This is a sound and practical division.

The *catarrhal* variety is attended with hyperæmia of the mucous membrane, dypsnœa, and increased secretion. There is hoarse voice and ringing cough, but the temperature rarely exceeds 101°. This affection may be preceded by cough and catarrh for a day or two, or the symptoms may come on suddenly and attain alarming severity in a few hours. If an active emetic be given at once, the symptoms generally subside, and in twenty-four hours the child is out of danger.

2. The *fibrinous form* is the typical variety of croup—it is a true tracheitis. The inflammation is intense and acute; it extends beneath the mucous membrane, and by involving the fibrous tissue pours out a plastic exudation which becomes transformed into a firm adhesive membrane. The disease begins with hoarseness of voice, a harsh ringing cough, and a sense of constriction in the trachea, arising from the absence of secretion. The symptoms are infinitely more severe than in the former variety, the pulse is rapid, dyspnœa is urgent, and the temperature soon reaches 103° or more. At length, organised exudation blocks up the trachea and larynx, which in favourable cases is either dislodged by vomiting, or resolution takes places with absorption. In unfavourable cases the false membrane, more or less, blocks up the tracheal canal and embarrasses the respiration, or it even extends down into the bronchi, and causes death by asphyxia.

Dr. Day contrasts diphtheria with croup, and proceeds to show that the latter affection attacks healthy children, and in districts where diphtheria does not prevail. Croup is a local diseases diphtheria is a constitutional one; croup is neither infectious nor contagious, diphtheria is both. Recovery from diphtheritic croup is slow, and there are sequelæ in the shape of paralysis of the muscles of deglutition, and albumen in the urine, which is not observed in croup. The pathological differences in the appearances of the false membrane found in diphtheria and croup are also contrasted, though it is admitted that in some few cases, the histological changes may bear a close resemblance—that is a plastic deposit may be sometimes seen in the larynx in diphtheria, as it is in genuine inflammatory fibrinous croup.

With regard to treatment, the writer puts great faith in the vapour bath, especially in catarrhal croup and in the early stages of fibrinous croup, and the value of tartarised antimony in effecting free and speedy vomiting. After the action of an emetic, he believes in the utility of calomel in the fibrinous form, and even two or three leeches over the thyroid cartilage, when the pulse is firm and hard, and the strength good.

When all remedies appear to fail he advocates tracheotomy, and recommends that it be resorted to as soon as resolution appears unlikely to take place.

HIGH DEATH-RATE OF DUBLIN—ROYAL SANITARY COMMISSION.

WE are pleased to notice the Commissioners adopted the wise course of bringing forward the district medical officers of health as witnesses. The advantages of having those gentlemen were obvious. They testified as to the wretched condition of the tenement houses. One medical officer said he would prefer sleeping in a dissecting-room to some of the tenements he had in his district. Overcrowding was complained of. The abuse of alcohol and its attendant evils upon the wives and children of the working classes were mentioned.

The witnesses also dwelt upon the want of proper street and domestic scavenging; flushing of the street channels; the keeping of manure heaps in various parts of Dublin; the want of public baths and washhouses, and convalescent homes for those recovering from infectious diseases; an

Digitized by Google

improved system of disinfection of dwellings and of clothes; the establishment of a refuge, where the occupants of a dwelling undergoing the process might be accommodated for the time being; and the want of a ward in each hospital, in which obscure cases should remain until the disease became developed. The mode of conveyance of the sick to hospitals was gone very fully into. The system of ambulances in preference to cabs was insisted upon forcibly.

The attention of the Commissioners was drawn to an erroneous impression as to the cheap rent an artisan pays for a tenement lodging in Dublin. It was shown that an ordinary-sized living-room sufficient to accommodate a married couple and children, could not, as a general rule, be had for less than half-a-crown per week; that the amount was frequently more, but seldom below that figure. It was emphatically stated by an experienced medical officer, that supposing a large number of tenement houses in Dublin remain undisturbed, an immense improvement would take place in their sanitary condition, provided the inspection of nuisances was better organised, and that the houses were inspected systematically. This could only be done in a satisfactory manner by having a register of such houses, and insisting upon their periodical inspection.

It is to be hoped, in view of the present limit to the operation of the Artisans' Dwellings Company, this practical suggestion may meet with the attention which it deserves.

The importance of independent supervision of the working of the Public Health Act was also recognised. There is no doubt that the inquiry into the many causes which combine to produce the notoriously high death-rate of Dublin would not have been complete without the valuable testimony afforded by those gentlemen who have painted in striking, but not exaggerated colours, the evils and misery which exist in those portions of the city wherein their work for the most part lies.

GUY'S HOSPITAL.

The present is a serious crisis in the history of Guy's Hospital. The traditions that have long guided its internal administration are being ruthlessly overthrown, and the consequences are likely to prove disastrous to one of the chief charitable institutions in the world, unless some check be speedily opposed to innovations as ill-advised in spirit as they are unnecessary in execution.

A few weeks since the late matron of the hospital retired under the regulations which provide for superannuation allowances after lengthy service, and a new head of the nursing department was selected in the person of the then matron of the Leicester Royal Infirmary. Under this lady the provincial hospital has obtained a very considerable reputation for the excellent nursing received by the patients in it, the credit being mainly ascribed to the arrangements and rules observed under the matron's supervision. We do not dispute any of the assertions made on this point; indeed we are ready to congratulate the late matron of Leicester on the good results she has already obtained, but we *do* insist that the same means for ensuring success cannot be employed with any hopeful anticipation n two su ch utterly dissimilar places as a small county infirmary and a large metropolitan hospital. The one is entirely unlike the other in its surroundings, in its administration, in its traditions and usage, and above all, especially in the nature of the circumstances under which it is worked.

In Guy's Hospital there is, as must be, a large number of trained sisters and nurses, by whom the instructions of the medical and surgical officers in attendance on patients, have for long been efficiently carried out. Enjoying a reasonable reputation for common sense, the nursing staff have been permitted a certain freedom in the matter of their personal appearance that should be denied to no one who is capable of self-government. As in all large institutions of the kind, a regulation uniform, neat and appropriate for the duties, has been worn, but no arbitrary commands affecting minute details have been issued till recently, a course of which the wisdom must be apparent. That the old system has been a good one, properly worked, results sufficiently prove. In several wards are found nurses who have held their place there for long periods of time, in some cases amounting to fifteen, eighteen, or even twenty years. The consequence is that they have become firmly attached to the places thus made familiar by lengthy association, and we can imagine the painful dismay with which one of the earliest orders issued by the new matron was received. This, to the effect that henceforth nurses would be subject to frequent changes from ward to ward, at the decision of the superior officer, is a most unwise proceeding for many reasons. We know of several cases in which it has been productive of fatal consequences; but even on the single ground of interest, there is the strongest reason to encourage an attachment on the nurse's part for a particular ward. We are told that a chief objection raised by the new matron against the system, is the fact that it permits *too great* an interest to be felt by the nurse for her patients, and that this is destructive to good nursing. The utterly illogical reasoning of this excuse is on a par with the action it dictates.

The question of dress is the first that aroused the new officer's indignation. By this rule, the neat and becoming familiar black was changed to grey, and an absolute order issued for the removal of all but a single article of jewellery, or other adornment from the person of the sister or nurse on duty. Though childish and contemptible in itself, it is worthy of note as indicating the entirely erroneous conception this lady has of the effect of cheerfulness and content on the sick. Her whole action seems animated by an impression that no influence other than that of officialism is exerted by the ward attendants on the suffering poor who are the objects of their ministrations. In many other ways she has exhibited the same absolute ignorance of æsthetic principles and their connection with the cure of disease; and the consequence has been that an uncompromising spirit of enmity has been aroused between her and the old tried servants, who have seen generations of patients pass from them benefited and cured, under a system that they grieve to see thus ruthlessly set at nought.

The following facts will briefly explain the present attitude of affairs:—

The new matron entered on her official duties November 1st.

Digitized by Google.

Through the reports which preceded her arrival, and bearing on her past rule, twelve of the best nurses of Guy's left at the end of October.

On arrival, the matron issued the following "orders":—

(1) Every probationer shall be required to sign an agreement to serve for three years; older nurses, one year.

(2) To dress after the fashion of the "Leicester uniform."

(3) To submit to a reduction in salary of £2 per annum, in lieu of tea, &c.

On compliance with these demands a certificate of efficiency would be granted on completion of service, but any probationer, or nurse, leaving prior to such term would forfeit three months' salary.

We have been very much disinclined to enter into these details, but as they are necessary to a clear comprehension of the case, as it stands, we have done so. The whole internal organisation of a vast charity is disturbed by the senseless arrogance of one officer. The bitterest ill-feeling is, it must be admitted with justice, excited by her persistent ignoring of the better nature of those who have the misfortune to be subject to her. The safety of a great number of helpless sick is unavoidably imperilled, for no fewer than thirty-eight tried and highly-qualified nurses have declared their intention of resigning their posts at the close of November. Many of the acts and speeches of the new matron are calculated to engender an impression detrimental to the authority she should wield, and especially do we complain that she has insisted on the nurses conforming to a certain ritual of religion.

When we hear that not one or two, but dozens of nurses possessing "the full confidence of every surgeon under whom they have served," feel themselves called on to sever their connection with a place after 10, 12, 14, or more years of service, it must be apparent that some urgent provocation to such a course has arisen. So long as this wholesale exodus continues the effective working of the institution will be paralysed, and, while this is so, the public for whom it exists, and the profession, whose first interest is expressed in "salus populi," have both, a primary right to inquire why the trouble has arisen, and to demand its immediate removal. We are assured that, with few exceptions, the charges insisted on are as repugnant to the medical and surgical staff as to the sisters and nurses; and we must confess to the greatest surprise that such a condition of things is for a moment permitted to continue when express disapproval has been pronounced on them by those who can best appreciate the influence they are exerting.

Earnest endeavour after improvement we always cordially hail, but arbitrary and indiscriminate insistence on points that only indicate a desire for petty authority, while most injuriously reacting on a valuable institution, we deprecate and unhesitatingly condemn.

THE DISCOVERY OF THE DIFFERENCE BETWEEN TYPHUS AND TYPHOID FEVERS.

It would seem from recent statements in the public press that there are persons who write for the papers on medical topics who are entirely ignorant of some of the most interesting literary facts relative to this subject. We do not pretend to support those who would not suffer the daily journals to discourse on medical topics; for we may be sure that the organs of public opinion will never give up their rights at the bidding of professional jealousy. Besides, there is no reason why they should, so long as they are able to employ the most capable pens in any of the professions. But it is admitted by all the best publicists that professional subjects should be treated by capable professional writers, who are bound by the honour of their position, as well as in common honesty, to use their influence for the public good, and to be very careful not to injure individuals. In questions of literary and scientific priority the public journals are perfectly competent judges, and indeed, we should expect when they touch on such questions that they will do it with a fulness and fairness too often wanting in the professional organs.

We have no Chairs of Medical History in this country, and the subject is, therefore, sadly neglected. Students labouring through an overcrowded curriculum give the go-by to all that does not tell at the examining board; practitioners find the claims of their art and the exactions of their patients absorb all their time, and so questions of literary or scientific priority, unless they happen to be complicated with unpleasant disputes between rival candidates for honour, are thrust aside as the useless, if innocent, amusements of a few learned, but rather curious men.

There are, however, many instances of the evils arising from the general neglect we have named, and of which a recent example is afforded by the errors of a daily contemporary on the history of typhoid fever—an error unfortunately unredeemed by the common honest practice of subsequent correction.

Commenting on Sir Wm. Jenner's recent address on the treatment of typhoid, the *Telegraph* ventured beyond its text into the history of the disease, and fell into the ridiculous error of attributing to the late Prof. Goodsir the credit of first distinguishing between typhoid and typhus—rendering the blunder still more remarkable by speaking of "the late" (*sic*) Dr. A. P. Stewart as following him. Now, Dr. A. P. Stewart is not only alive, but is still in practice, in London; he has the greatest merit in establishing the distinction, while Goodsir has no part whatever in the matter. It is doubtful if the learned anatomist took any special interest in the question, for he only wrote a casual paper in 1842, not thought worth including in his works by the very able editors who were intimately associated with him during his life.

Now, Dr. Stewart's work in the Glasgow Fever Hospital extended from 1835 to 1838. Thence he went to Paris, where, early in 1840, his conclusions were brought before a medical society. They were published in Paris, and afterwards in Edinburgh, and his work may be said to be completed at that date. How, then, can any question of priority be raised after 1840? The writer in the *Telegraph* has made an egregious blunder, and it is to be regretted, for the honour of the press, that he should not be willing to acknowledge it.

Not that this was the first enunciation of an idea that these diseases were distinct. On the contrary, it is as a full demonstration of their differences that Dr. Stewart's

Digitized by Google

work must be regarded. Gerhard and Pennock, of Philadelphia, had, simultaneously with Stewart, arrived at similar views, and their observations were published in the *American Journal of the Medical Sciences* in 1837. Thus, in time of publication, they were actually before Stewart, whose work was quite independent, who had begun it in 1835, when distinctions were made known in the Glasgow Fever Hospital.

The difference in the eruptions was pointed out to Dr. Perry by Dr. Peebles early in 1835, Stewart being present, and from this date the differences were recorded in the case-books; but even Dr. Perry, who wrote in the *Edinburgh Medical Journal* the following year, spoke of the abdominal affection as occurring in about 1 in 6 of "*those who died of typhus.*" In fact, those who look into the literature of fever will soon be convinced that prior to Stewart's work French pathologists regarded the *dothiénenterite* of Bretonneau as the ordinary form of fever, while the British school, having typhus constantly before them, regarded the abdominal lesion as one of many complications which might occur—a conclusion which Drs. Tweedie and Southwood Smith had previously formulated as the result of their experience at the Fever Hospital. We might account for the opposite opinions of English and French physicians at that date, perhaps, by speaking of typhoid as Paris fever, and typhus as British fever. Dr. Stewart demonstrated that the two diseases existed side by side in Great Britain, that these differences were "so marked as to defy misconception, and to enable the observer to form, with the utmost precision, the diagnosis of the nature of the disease and the lesions to be revealed by dissection." The proof was such that the *Archives Générales* concluded a review by the statement that it was proved by his researches that there were in England two distinct diseases —viz., typhus and typhoid.

Notwithstanding the completeness of the proof, the doctrine now generally adopted did not meet universal acceptance, and this is not to be wondered at when we remember the fascination of the study of the analogies of diseases and the influence of those who had taught the opposite view. The late Dr. Murchison in 1841, with the full evidence before him, was unconvinced, and endeavoured to show (*Brit. and For. Med. Chir. Rev.*) that the two fevers were only varieties, not distinct species. At a later date he entered on his duties at the London Fever Hospital with this opinion, but in 1862 had the manliness to avow a change in his views as the result of his "subsequent observations, aided by the convincing arguments of Drs. Stewart and Jenner." The mention of the last name reminds us that his writings and teachings have given a great impetus to Dr. Stewart's doctrine. In fact, the other day we smiled to hear the demonstration attributed to him by an admirer who had evidently forgotten that his first paper at the Royal Medical and Chirurgical Society was read in December, 1849, nine years after French authority had pronounced Dr. Stewart's demonstration complete.

RATIONAL CHEAP DIETARIES.—II.

After these preliminary observations we may proceed to the practical part of the subject, and survey some of the ordinary combinations in common use, and contrast with them some new combinations. Thus we find beans (a vegetable rich in albuminoids and starch) eaten with fat bacon (rich in hydro-carbons). We find boiled beef eaten with turnips and carrots as well as potatoes, the whole forming a good combination from every point of view. Then we have the appetising Irish stew, made with meat consisting largely of fat, and potatoes with some onions. These three selections illustrate the different combinations required for different workers. The first, beans and bacon, is a food-combination suited to very hard work, as the agricultural labourer in harvest time, or the navvy. A similar combination may be made economically all the year round as follows, the quantity being calculated for one person :— Take half a pound of fat striped bacon and cut it into strips like the little finger; then cut up a large Spanish onion, and put them in a basin in the oven, with some pepper and a little salt. Cook them partially; in the meantime some Egyptian lentils can be washed and scalded, after which they are poured into the basin, and the whole well mixed together can be put into the oven for ten or twenty minutes. Here we have the albuminoids, the fat, the starch, and the antiscorbutic onion combined in a dish far from unpalatable, and of the highest food-value. Or, in another form, the same combination may be obtained :— Place half a pound of striped bacon and a Spanish onion shredded into a pie-dish in the oven till fairly cooked; place half a pint of dried green peas into water the night before, adding a pinch of carbonate of soda to the water, and let them soak; while the bacon and onion are in the oven the peas can be boiled; when done the peas are poured into the pie-dish, and the dish is put in the oven for a few minutes. This is even more appetising than the lentils and bacon. Haricot beans can be made into a like dish, and, as the "baked beans and pork" of New England, are delicious. This combination can now be bought in quart tins, and is very good indeed. Such food-combinations as those just given form a dietary on which the hardest-working labourer will not lose strength, and can work with comfort, while the cost price is within reach of the humblest means.

Then take the second form of food-combination—boiled beef, with turnips, carrots, and potatoes—a combination of fair food-value, quite sufficient for a huntsman, a farmer who works, or for a gamekeeper. An equal food can be procured as follows :—Place half a pint of dried green peas in water as before, let them soak all night. Take three-quarters of a pound of mutton, pretty fat, cut it in pieces, put it in a pie-dish with a large Spanish onion shredded, a large carrot and a large turnip cut in pieces; then add pepper and salt, pour in the peas, and then cook altogether in the oven or in a stewpan. With or without potatoes this dish is excellent. Or take three-quarters of a pound of fat pork, cut very small, and shred a large Spanish onion; put both, with a little water, pepper, and salt into a stewpan, and cook. This may be eaten with potatoes or rice, and is decidedly appetising. As potatoes are going to be dear this winter, the cabbage is attracting attention. As ordinarily cooked, viz., cut in four and plain boiled, cabbage is little less than repulsive; but if the heart of a good cabbage, especially a Savoy, be cut in four and boiled, and then cut into pieces about the size of the

Digitized by Google

thumb-nail, a piece of butter and a good lot of pepper and some salt being added, and the whole stirred well together and put into the oven for ten or fifteen minutes, cabbage will be found very appetising. By so cooking the cabbage is deprived of a large quantity of its water, while the butter penetrates its substance, and between the two cabbage is likely to take a higher culinary position than has hitherto been accorded to it.

Another way of cooking cabbage which makes it very toothsome, is to shred the heart of a large cabbage along with a large or two small Spanish onions shredded; put them, with a little water, a quantity of pepper, and some salt, into a stewpan and cook. This forms an excellent and appetising vegetable, especially in cold weather. If half a pound of pork, chopped up, be added to this, a capital combination is formed, giving a fairly high food-value at a small cost. In all these combinations given above the oven is not indispensable, and the stewpan is quite sufficient for most purposes. Then, if economy is very pressing, half a pound of meat instead of three-quarters may be substituted, the same being indicated where the patient is inclined to lithiasis in any of its forms. Such food is quite sufficient for the body-needs of clerks, light handicraftsmen, and ordinary adults. Where there are growing children more albuminoids are indicated, but these can be cheaply supplied by the split pea, the dried pea, the lentil, or the haricot bean, as under the first division of foods made here.

As to the third division, represented by the Irish stew, it can find its equivalent in the second series of dietaries just given above, or by eating potatoes with the dishes.

Lentil soup is made by boiling lentils and putting them through a sieve, or pounding and pressing them through a colander, and again boiling them with chopped onions, carrots, and turnips, some pepper, salt, and a little brown sugar; so prepared, lentil soup is regarded by most people as delicious. Where there is a dinner of cold meat lentil soup might be served first, then the cold meat with potatoes and cabbage cooked as given above, finishing off the meal with a piece of cheese and a crust of bread. Such a meal is enough for almost any workman, and could be put on the table by any artisan's wife who chose to take the trouble.

And now that cheese is mentioned, it may profitably engage our attention for a few minutes. The great objection to cheese is that with most people it is very indigestible, yet Dr. Beaumont found with Alexis St. Martin that toasted cheese was one of the foods most readily and quickly digested. The great factor in the alleged indigestibility of cheese is that it is not sufficiently subdivided before it reaches the stomach, and so the gastric juice fails to dissolve it readily. As toasted cheese, Welsh rarebit, as cheese soufflée, and even as maccaroni cheese, the cheese is not easily masticated and reduced to particles small enough for comfortable efficient digestion. Yet if cheese is properly cooked it is quite digestible. From its present price cheese can compete with butcher's meat most successfully; but for its proper employment as a food totally new dishes to those in common use are required. Cheese is rich in caseine, one form of albumen; it is also rich in fat, the hydro-carbon of highest food-value; consequently it goes well with farinaceous articles of diet. Cheese and bread form a regular staple dietary with our working classes of all kinds, especially in the country. But as a cooked food cheese is rarely eaten. Why? It is difficult to say. If cheese be finely grated, or cut up like suet for a pudding, it can be mixed with a milky rice pudding, and forms a most palatable dish. With hominy it is delicious. Let half a pint of hominy be soaked over night, then boiled, and half a pint of milk added; break up half a pound of cheese into fine fragments, stir this in the boiling hominy and milk, and then put the whole into the oven (or stewpan) for twenty minutes. The taste of this is delicious, and as the particles of cheese get lost to view among the units of the hominy, they are readily dissolved by the gastric juice. In this form cheese can be taken satisfactorily even by a confirmed dyspeptic—by one, at least, anyhow, our experience of this food with dyspeptics not extending further than this one case. What is left over from dinner forms an appetising article for breakfast, either cold or warmed up. With lentil soup, this dish of cheese and hominy will give a perfect dinner, all the requisite constituents of our food being present. Cheese has recently been chiefly used among the more affluent classes as a tasty adjunct to an ordinary dinner. But cooked as above it will soon become a material factor in the poor man's dietary. Cheese must be intelligently cooked to be at once toothsome and digestible. Still the methods of cooking it given above are very simple, and involve no elaborate culinary arrangements.

Perhaps many readers, especially in the country, will ask, What is "hominy?" It is Indian corn, not ground, but finely cracked, so that each unit is about the size of a small pin's head. It is largely used in the United States, boiled in milk; and as such, forms a capital porridge; better even than oatmeal porridge, in the opinion of many who love that compound, so associated with their early recollections. Oatmeal porridge disagrees with some people who relish and enjoy hominy porridge. Then plain boiled and put away *en masse* in a pot it cools into a gelatinous-looking mass, slices of which are fried in the fat of bacon or pork, as a fritter; and on such "hog and hominy" most Western Americans are raised, men of far superior build to the lean being raised in the old New England states. An ordinary rice pudding of a milky order can have its food-value raised immensely by adding to it cheese either grated or in tiny fragments, and is very palatable. Lentil soup with these combinations of farinaceous matter, with cheese, forms a dinner fit for any person; the whole supplying in easily digestible form the requisite constituents of our food.

Notes on Current Topics.

The Vacant Irish Surgical Baronetcy.

THE *Dublin Evening Mail* has recently re-opened the question, to which we devoted much space on a former occasion, of the continuing existence of a hiatus in the roll of medical distinctions due to Ireland. The *Mail* speaks as follows on this subject:—

"Though it is impossible for a busy public to give everyone in this world his true deserts, still it is easy for a Sovereign to choose a fit and proper member of any pro-

Digitized by Google

fessional body, and, by honouring him, to confer honour on his professional brethren. This, we think, ought to be done in Dublin. Nor is it any new thing we suggest, but merely a revival of an old-established honour. There was a time when Dublin could boast of her medical and surgical baronets. Sir Henry Marsh and Sir Philip Crampton represented physicians and surgeons with equal skill and urbanity. On the death of the former Sir Dominic Corrigan was selected by the Liberal party as the recipient of the vacant honour. But since 1857, when Sir Philip Crampton died, no further recognition of medical ability and devotion has been given, and to this day the surgical branch of the profession has remained absolutely neglected. In London we find the following medical baronets—Sir W. Gull, Sir W. Jenner, Sir J. Paget, Sir T. Watson, Sir G. Burroughs, while another, Sir C. Ferguson, died not long ago. It would appear as if the old motto of 'No Irish need apply' had still some force left, even in connection with a profession of which Ireland is justly proud. But we dismiss this idea when we reflect how honours have been showered upon every other profession in Dublin. Barristers, solicitors, architects, musicians, managers of places of public amusement, all have had favours and honours conferred upon them. Lord Mayors in Belfast and Cork, as well as in Dublin, have received the just and suitable reward of arduous duties. But the medical profession remains undecorated. It is silent under its neglect, but we have no doubt that the neglect is keenly felt, and will make itself appreciated sooner or later. It may well be asked, why is it that since Sir Philip Crampton's death none of his successors have been considered worthy of the distinction conferred upon him? We do not intend to mention any names in connection with this subject; it is quite unnecessary. We imagine the medical profession would hail the complimnnt so long withheld with equal pleasure whoever was marked out to receive the distinction."

The complaint thus uttered by our contemporary must surely strike anyone as a just and reasonable expression of disappointment at the undeserved slight to the Irish profession in this matter. There can be no reason for taking from Irish surgeons one of the rare distinctions which they had hitherto possessed. There are members of the profession to-day as eminent, as independent, and holding as high a social rank as those who adorned any epoch of Ireland's history, and it is difficult to know why Her Majesty's high name should be allowed to remain under the shade of a disappointed feeling on the part of our profession when that feeling could be at once dissipated by the selection of a successor to Sir Philip Crampton. It is certainly a wise policy for Governments to allow no cause for discontent to exist where it can be readily removed, and it cannot, we think, be judicious for Her Majesty's advisers to leave the profession to draw unpleasant comparisons between the lavish distribution of medical honours in England and Scotland, and the niggardly refusal to Ireland of the one distinction which has remained so long unapportioned. Grumbling is always an unhealthy temper, and in this instance there is no just cause why the powers that be should not at once restore contentment. They have only to select, and everyone has in his mind where the selection might be best made.

The Etiquette of Medical Titles.

Dr. Frazer, of Aberdeen, communicates to the last issue of the *Medical Times and Gazette* his well-considered replies to several questions of medical etiquette. Therein we find the following statement, which we quote with approval as representing the honest truth of the matter:—

Q. What are the proper rules to be observed with respect to the etiquette of titles in the medical profession?

A. The first and most obvious rule here is that no man should use, either in reference to himself or to others, any other title than that to which they can legally lay claim. For instance, one who is not in possession of the doctorate should not apply it to his name either verbally or in writing. Such an assumption, besides being in general an indication (and viewed as such by the profession and by people of intelligence) of ignorance, vanity, and cupidity, if not of actual dishonesty, would have the effect of invalidating any official transaction or document, and thus of bringing discomfiture and loss on the person who is guilty of it. But although a medical man should not, *sua sponte*, either directly or indirectly sanction or encourage the application of "doctor" to his name unless he have diplomatic authority to that effect, yet in those parts of the country and among those classes of society where this title is a sort of generic or general appellation given to members of the profession, it would be impossible, without the greatest affectation, to avoid the designation, and good taste, rather than otherwise, will frequently be displayed by giving way to the current of social usage, both in accepting the title and in according it to others in the same position as himself.

Murder and Suicide by a Medical Student.

A fearful murder, followed by the suicide of the murderer, took place last week, about half-a-mile from the village of Mosside, in the co. Antrim. The victim is a farmer named M'Vicker, and the murderer was his nephew, Robert M'Vicker. Young M'Vicker had been a medical student for two sessions, and was being educated by his uncle, who, it would seem, was a man of some means. The uncle had promised to get £20 out of the bank, in order to enable young M'Vicker to resume his studies this session. The old man did not keep his promise; the nephew became greatly enraged. He eventually struck the old man a violeht blow with a hatchet, causing almost immediate death. Two brothers of the deceased were present, but, being old and infirm, they took no steps to reveal the tragedy. A diligent search was made for young M'Vicker, but he was nowhere to be found. His body was at length discovered in a well close to the house. The old man had taken a deep interest in his nephew, and had paid far his education at the Ballymoney Model school, and afterwards at College. The coroner's inquest has not yet been held.

Army Medical Department.

The long-expected appearance of the newly-framed provisions in reference to the Medical Service of the Army has been hailed in all quarters as an indication of the desire that is felt on the part of the authorities to initiate the much-needed reforms. So far there is but little to complain of, and satisfaction is expressed that so much has been accomplished. It must be said, however, that all the clauses of the new schedule do not entirely meet the views of the profession, or that section of it most interested in the scheme. It is a question whether the maximum limit

Digitized by Google

of twenty-eight years, beyond which candidature will be no longer possible, is not a grave error. In a great number of instances men would seek to enter the Queen's service after a preliminary experience of general practice, if the path were open to them; and that such men are more fitted to discharge the duties efficiently, than a student fresh from his hospital, there can be no possible doubt. As it is an honourable, so it is an onerous career that lies before the army-surgeon, and the wider his acquaintance is with men and manners, to say nothing of an extensive familiarity with the phases of disease, the more probably will he become a useful and capable attendant on the injured, whether in time of peace or war. In another aspect, too, we feel the provision limiting the age to twenty-eight is an unwise one. A considerable proportion of medical students consists of men who only at a comparatively late period of life embrace medicine for a profession; these are, with few exceptions, such as enter on its study with enthusiasm because of a distinct predilection; and are especially such as, being matured in mind and body, would prove invaluable in the discharge of duties where personal influence exerts so considerable an effect on the maintenance of discipline. Other reasons might be stated, but these seem to us of sufficient weight to merit the attention of the War Office, ere a final judgment be pronounced. The present document is only the precursor of the formal warrant, but it contains essentially what will be found in the forthcoming decree. The arrangements under which retirement will take place seem conceived in a fairly liberal spirit, and the effect of the issue will be to improve the service and elevate it out of the miserable slough into which it has of late years been sunk.

Guy's Hospital.

We draw attention in a leading article to a very undesirable state of affairs existing at Guy's Hospital at the present moment, due to the arbitrary action of the newly-appointed matron. Nothing good can come of such ill-advised interference with established usage; and we hope to hear that some steps have been taken to restore peace and quietness to the hospital over the water. It would be a dread calamity to the populous district in which the charity is situated if anything occurred to obstruct the working of the hospital: and judging from the present aspect of affairs such a contingency seems not only possible, but inevitable. The wholesale exodus of nurses that is threatened will, if it take place, lead of necessity to a "block," unless their places can be immediately filled, a matter of almost insuperable difficulty, for nurses do not grow on trees, but must be trained to be of use, and are in such demand that the supply is by no means adequate to meet it. We trust, however, that the evil may be averted.

Elections at St. Bartholomew's.

Currency is given by our contemporary, the *Students' Journal and Hospital Gazette*, to a rumour asserting that Professor Lister, of King's College, and Mr. Jonathan Hutchinson, Senior Surgeon to the London Hospital, are candidates for the vacant surgeoncy at St. Bartholomew's Hospital. The probable effect of Professor Lister's immediate presence on the most recent of his antagonists, would be the conversion of Mr. Savory to the truths he is unwilling to admit. Some surprise has been expressed that the address he lately delivered at Cork has to this time elicited no reply from the perfecter of the antiseptic treatment; and there is, it must be confessed, some reason to regret that the duty of exposing the weakness of the attack has been left to other hands. Excellent as many of these have been, they would gain much from the authoritative assent of Professor Lister, and we think it is due from him to acknowlenge the defence. That he has conclusively answered all arguments in the past, while being true, is not enough of itself; for all great truths have ultimately been accorded a universal belief only after long-continued iteration of their force. Antiseptic surgery is an essential of progress in scientific medicine, and he, most of all, in whom it originated, should be unceasing in the promulgation of its doctrines.

Newspaper Puffing.

Mr. Labouchere's talents are manifold, but perhaps nowhere better displayed than as a puffing agent on behalf of medical practitioners. In a recent number of *Truth*, we are treated to a most ostensible advertisement on behalf of a medical man, the more reprehensible since it does not take the ordinary form of paid-for announcements. In a column of news and chat, Dr. Hypophosphite Churchill was held up as a miraculous healer, who had restored the maimed, and recovered from the embrace of death an emaciated skeleton, whose last moments seemed fast fleeting past the barrier of earth. By resorting to Dr. Churchill, the paragraph continued, and remaining a month under his treatment (? hypophosphite), the most marvellous change was wrought, and from a lanky, weazened caricature of humanity, he was converted to a hale and hearty English gentleman. A more arrant advertisement we have rarely seen, or one more calculated to bring discredit on the general medical profession, and we regret the unwise impulse that induced Dr. Churchill to avail himself of the "Truth"-ful news-sheet as a means of disseminating his vaunted excellence of treatment. We are anxious to know if this consisted in anything more than administration of *hypophosphites*, and if any other practitioner has ever seen similar startling results follow its employment.

Signs of the Times.

Medical men have indirectly contributed to the spread of pauperism by giving medical advice and medicine gratuitously. We notice, with pleasure, in a contemporary, a paragraph headed "Medical Relief on a Loan System," which indicates an awakening to the folly of giving so much medical assistance for nothing, and which we take to be a sign of better times. Our contemporary tells us that at the annual conference of guardians—Surrey, Kent, Berks, Hants, and Sussex—lately held at Brighton, at the instance of Mr. B. Fleming, one of her Majesty's inspectors, a resolution was passed unanimously urging that relief, and especially medical relief, should be more constantly given on loan. This system has been tried in Bradford with the effect of reducing medical relief 90 per cent. The medical profession will regard this action of boards with satisfaction, as

Digitized by Google

tending to restore some of the lapsed respect for medical services, the absence of which so deeply demoralises the community.

Wares of any other kind are regarded as things to be paid for, but medical services and advice—even in the dead hours of the night—are claimed as a right, even without pity for the men who have them to give. If all boards would take the same course, the most powerful assistance yet devised would be given to provident dispensaries. We commend the same principle to the serious consideration of the Committee of Charitable Dispensaries and Hospitals, of course with all precautions against hardship to the really poor.

The Metropolitan Water Supply.

We are particularly glad to find that the water supply of London is at last to receive attention in the next session of Parliament. Mr. Cross has moved his colleagues in this important matter, as we see by an advertisement amongst the Parliamentary notices, headed "The Metropolitan Water Works Purchase." Therein it is stated that it is intended to apply to Parliament for borrowing powers for the purpose of acquiring the eight large water companies and provide for their dissolution, and create a new trust, to be called the "Metropolitan Water Trust." We have considerable misgivings as to the creation of central authority and a new set of officials, and we fear this proposition will start a fresh difficulty when it comes before Parliament. A group of Commissioners, responsible only to a Minister of State with his hands already full, and in every way independent of the community every whose interests they will be supposed to watch, will scarcely turn out a great gain to the water consumers of London. From an experience of the Board of Works and School Board, we can hardly expect to be favoured with any great improvement in quality and quantity of water, with constant service, at a reduced rate of charge. London, too, must not be looked at from a provincial point of view; it is far too vast to be placed under any single minister or authority. To attempt anything of the kind would, we fear, be only delivering the water supply from the hands of King Log to that of King Stork. It is, however, quite likely that Parliament may choose some other way out of this difficulty. We have London divided into ten Parliamentary divisions, and why should we not have the water supply partitioned out in a similar way, and placed in the hands of a local authority, easily accessible to the rate-payer, and who will surely be better acquainted with the wants of each district than a central municipality of London acting under a Minister of State.

Medical Pluralism in Dublin.

An appointment has been made to the position of Medical Officer of the General Post Office in Dublin, vacated by the resignation of Dr. Toler, and the selection made claims from us a protest on behalf of the profession. We are bound by every sense of justice to remonstrate against the aggrandisement of one gentleman, however remarkable for his surgical skill and professional industry, because he is the lucky relative of a luckier judge, and we submit that it is an unequivocal abuse of Government patronage to shower upon the head of an individual victim, the favours which ought to be fairly distributed The new medical officer of the Post Office was, not long ago, medical officer of the Clondalkin Dispensary District, near Dublin. Simultaneously with the elevation of his brother to one of the highest seats on the judicial bench he becomes surgeon to a metropolitan hospital, and since that day the fortunate gentleman has been simply overwhelmed with good fortune. He was made Surgeon of the Government Lock Hospital in priority to a host of deserving candidates. Then he was slipped into the office of Physician to the Kilmainham County Jail with the assent of Government; next he appears as the chosen Surgeon to the General Post Office on the nomination of the Postmaster-General; and finally we hear that the Medical Officership of the North Dublin Union is waiting his acceptance. We have not a syllable to say to the discredit of the gentleman's professional or social status, nor do we suggest that he may not prove an efficient Post Office surgeon; but we suggest that the recognition of his merits has been somewhat sudden and appreciative, and that he is obviously not one of those flowers "born to blush unseen and waste their sweetness on the desert air." We think the learned judge and the meritorious doctor may now be reasonably satisfied, and that some other member of our profession may be allowed to hope for official preferment. By the time the gentleman in question visits the wards of his hospital, teaches his class, does his operations, and lectures his pupils, drives to Kilmainham and complies with the notoriously *exigeant* requirements of the Prison's Board, gets back to the Post Office and transacts the day's business of his office there, begets himself to the Lock Hospital and passes his many lady patients at that institution through his hands, and then returns home to receive the visits of importunate private patients, we imagine he will have well earned his repose and the gratitude of his country, and can afford to dispense with the luxury of visiting the paupers in the North Dublin Union. Let us hope that he may permit that privilege to some *confrère* who has no relative on the bench.

Surgical Society of Ireland.

The opening meeting of the Surgical Society of Ireland was held on Friday night last, the 21st inst., at the Royal College of Surgeons in Ireland. The meeting was very largely attended, the President of the College, Dr. Mapother, occupying the chair. and being supported by Dr. McClintock, the Vice-President, and the leading members of the surgical profession in and about Dublin. The President, abandoning judiciously the habit of offering to the Society a *rechauffé* of the work of past sessions, and the hopes for the future, devoted his address to the subject of "Shock." We expect to publish fully that address in an early number. Mr. Swanzy followed with a paper on "Sclerotomy," and Mr. Thomson, of the Richmond Hospital, with a communication on "Trephining."

Health of Dublin.

The deaths registered in the Dublin district during the week ending the 15th November, represent an annual

Digitized by Google

mortality of 30·1 in every 1,000 of the population. The average rate in eight large town districts of Ireland (including Dublin), was 27·7, and in twenty large English towns (inclusive of London) 22·8; in Glasgow the rate was 19·3; and in Edinburgh 19·1. In the Dublin district the deaths were 182. There were 43 from zymotic diseases, being 5 over the number for the same week of the last ten years: they comprise 4 from small-pox, 1 from measles, 19 from scarlatina, 1 from diphtheria, 3 from croup, 7 from fever (3 typhus, 2 typhoid and 2 simple continued fever), 1 from erysipelas, 2 each from dysentery and diarrhœa, &c. The registered deaths from small-pox are less than in any of the preceding four weeks, and the hospital statistics regarding this disease compare favourably with those for any week since that ended 23rd August last, only 12 new cases having been admitted during the week; 23 patients were discharged, 5 died, and 67 remained under treatment on Saturday last, being 16 under the number in hospital at the close of the previous week. Although the deaths from scarlatina are numerous, and, in fact, very much over the number in any week since the close of the year 1874, it is satisfactory to find that there has been a slight diminution in the number of new cases admitted into the principal hospitals, the admissions last week being 14, against 17 in the preceding week, and 18 in that ending 1st inst. But few cases of fever, pneumonia, or measles were admitted into hospital during the week.

Baby Farming.

THE public mind has received a shock not easily to be forgotten from the Cheshire baby-farming revelations, and it is therefore not to be wondered at that the bare mention of a probable recurrence of so terrible a business should arouse even the Metropolitan Board of Works into action.

It appears that, in consequence of statements made to one of the magistrates of the Wandsworth Police Court, as to an alleged infringement of the "Infant Life Protection Act" at an Orphanage in College Street, Putney, a committee was appointed to inquire into the circumstances. From the report presented at the ordinary meeting of the Board, on Friday last, we gather that this Orphanage was established by Miss Hall in 1877, and that she carried it on up to June last without organised supervision of any kind. During the period named, the greater part of the inmates of the Orphanage consisted of infants and children of from one to two years of age, and money payments, varying in amount, were received from either parents or friends towards their maintenance. On a close investigation, the charges of neglect were not substantiated, although the late and the present medical attendants of the Orphanage differed considerably in their statements. It did not appear either that the establishment itself was not suitable for the reception and keeping of infants, although it was a recommendation of the committee of investigation that in future very young children should not be received. The vicar of Putney, and other persons living in the neighbourhood, spoke of the work of Miss Hall in terms of praise. Nevertheless it has been wisely determined to turn over a new leaf, form a committee of management, and place the Orphanage on a similar footing to like institutions. For the sake of all concerned, all such places should be above suspicion, and this can only be secured by independent and effective supervision. The public should be thoroughly assured that helpless children are well cared for in every way—lodged in a well-ventilated building, carefully and properly fed, and kept in as healthy a condition as is possible.

There is just one other point of view from which the toleration of orphanages amongst us may be looked at, as to whether, with the well-greased machinery of the Local Government Board, devised as it is for supervising and attending to all the wants of the indigent class, they can really be needed; whether they do not rather give countenance, in some shape or way, to the devilish work of those monsters in human form who strive to make baby-farming a profitable business.

Postponing Death.

A REMARKABLE instance, that indicates a new field of usefulness for nitrite of amyl is related by Dr. E. A. De Cailhol in the *St. Louis Clinical Record*. He had been for a long time attending a young woman with phthisis, and had prolonged her life for a considerable time. The fatal day came at last, however. He was summoned by the friends, but found the patient lying pale, cold, and cyanotic, with gasping respiration and tracheal râles. He assured those about her that he could do nothing more, and that nothing could delay the fatal termination. He was entreated, however, to spare no effort to prolong her life. Thereupon he administered three drops of nitrite of amyl by inhalation. Very soon the pulse became fuller, colour returned to the face, the breathing was easier and the patient was able to swallow and converse. After a time the depression began to return; amyl was given again with a slightly less marked effect. Its administration was thus continued during the day and into the evening, when death at length came on. It had been postponed for more than twelve hours, much to the gratification of the friends.

The Cinchona Cure for Drunkenness.

DR. HAYNE, Superintendent of the Home of the Inebriates, San Francisco, writes thus of it, after full trial, in the *Western Lancet*—

In no single instance have I found it to possess the slightest power in disgusting the patient with liquor or in any way diminishing his or her appetite or craving for intoxicating drinks. On the contrary, they have all freely confessed to me that the anticipation and the pleasure of a drink was as strong as ever. In no case have I seen whiskey refused when offered, and in the majority it has been asked for. I know of an instance, in private practice, in which a person has stayed at home and taken the remedy all day, for several days in succession, and gone out in the evening only to be brought home thoroughly intoxicated.

THE *Chemist and Druggist* says that very large Government contracts for quinine, cinchonidine, and similar drugs have been announced within the last few days. It is said that as much as 60,000 ounces of quinine are required.

Digitized by Google

THE will of Dr. Patrick Black, late physician to St. Bartholomew's Hospital, who died on the 12th ult., was proved on the 5th inst., the personal estate being sworn under £60,000.

IN surgical instruments, and mathematical and astronomical apparatus, says the *Revue Industrielle*, French workmanship has deteriorated so much that the attention of the Government has been directed to the subject.

DR. SHINKWIN has been appointed lecturer in surgery in Queen's College, Cork, in the room of Dr. Tanner, who has been granted six months' leave of absence on account of ill-health.

THE death is announced of Dr. Chenu, formerly at the head of the Army Medical Staff of France, and the author of a treatise on the "Mortality of the French Troops in the Crimea," whither he accompanied the expedition. He was seventy-one years of age.

AMONGST the names gazetted on Friday last for the distinction of members of the Military Division, or Companions of the Most Honourable Order of the Bath, appear those of Deputy Surgeon-General Alexander Smith, M.D., and Deputy Surgeon-General Hendley, M.D.

OWING to the growing increase in the death-rate of children of tender years in Paris, the Minister of the Interior has written a circular to the Prefects, ordering them to draw up regular reports as to the causes of this alarming mortality.

A QUACK doctor well known in many towns of Cornwall and South Devon under the title of Doctor Dick, was tried at the late Exeter Assizes, charged with having procured a miscarriage in the case of a married woman who had consulted him. He was found guilty, and sentenced to five years' penal servitude.

STAINS or marks of any kind made with nitrate of silver solution or bath solution may be promptly removed from clothing by simply wetting the stain or mark with a solution of bichromate of mercury. The chemical result is the change of the black-looking nitrate of silver into chromate of silver, which is invisible on the cloth.

IN the principal large towns of the United Kingdom the rates of mortality per 1,000 last week were—Sunderland 17, Bradford 18, Plymouth 18, Edinburgh 19, Glasgow 19, Brighton 19, Birmingham 19, Bristol 20, Manchester 20, Wolverhampton 21, Norwich 21, Oldham 22, Sheffield 22, Salford 23, Portsmouth 23, London 23, Newcastle-upon-Tyne 24, Nottingham 24, Leeds 25, Liverpool 26, Leicester 26, Hull 27, and the highest rate 30 in Dublin.

WE understand that the governors of the House of Industry Hospital, Dublin, have decided to appoint a salaried resident at the Hardwicke Fever Hospital. The salary is fixed at £30, and the officer will also have the advantage of free apartments, fuel, and light. Mr. Dennehy, who was mentioned in most complimentary terms by Dr. McDowel in the course of his recent introductory lecture for his devotion to his duties during the last small-pox epidemic, has been appointed first occupant of the office.

IN the principal foreign cities the rates of mortality according to the most recent weekly returns were—in Calcutta 25, Bombay 31, Madras 34; Paris 24; Geneva 19; Brussels 26; Amsterdam 22, Rotterdam 27; The Hague 16; Copenhagen 32; Stockholm 20; Christiania 12; St. Petersburgh 29; Berlin 23, Hamburg 25, Dresden 19, Breslau 27, Munich 37; Vienna 25; Buda-Pesth 28; Rome 34, Naples 28, Turin 26; Alexandria 34; and New York 20 per 1,000 of the various populations. Measles caused 21 deaths in Copenhagen, and fevers 23 in Rome.

THE medals awarded by the Council of the Royal Society for the present year are:—The Copley medal to Professor Rudolph J. E. Clausius, of Bonn, for his well-known researches upon heat; the Davy medal to M. P. E. Lecoq de Boisbaudran for his discovery of gallium; a Royal medal to Mr. William Henry Perkin, F.R.S., for his synthetical and other researches in organic chemistry; and a Royal medal to Professor Andrew Crombie Ramsay, F.R.S., for his long-continued and successful labours in geology and physical geography. These medals will be presented at the anniversary meeting of the society, on December 1, when Mr. W. Spottiswoode will deliver the annual address as President.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

THE return of births, marriages, and deaths in the eight principal towns in Scotland says that the death-rate was during the week ending with Saturday, the 15th November, 1879, was 18·7 per 1,000 of the estimated population. This rate is 3·7 under that for the corresponding week of last year, but 1·3 above that for the previous week of the present year. The lowest mortality was recorded in Dundee—viz., 14·8, and the highest in Perth—viz., 23·4. The mortality from the seven most familiar zymotic diseases was 3·6 per 1,000, being 1 per 1,000 above the rate of the last week. The increase occurred chiefly in deaths from fever and diphtheria (including croup).

LONGEVITY IN SKYE.—The case of Christy McPherson, who is now in her 107th year, was brought under the notice of Her Majesty by Dr. Jeffries, the parish doctor of Sleat. Her Majesty sent the woman £3, and the doctor also brought Christy's case before Mr. Wm. Toms, F.S.A., the author of "Longevity of Man." This remarkable old woman is able to move better than a few years ago. She is not bedridden, but can get up daily with little assistance.

ST. ANDREW'S UNIVERSITY ASSESSORSHIP.—The election of an Assessor to represent the General Council in the University Court in room of Dr. Richardson, whose term of office expires, falls to be made at the approaching General Meeting of Council on Friday, the 28th inst. The London Committee of the University had the subject before them at a meeting on Tuesday the 18th. The Committee were of opinion that, in view of impending university legislation, it was most import-

Digitized by Google

ant that the Council should be represented by a gentleman residing in London who is conversant with the duties of the office, and by an unanimous vote they declared in favour of the re-election of Dr. Richardson.

EDINBURGH MEDICAL MISSIONARY SOCIETY.—The annual meeting of this Society was held on the 2t0h inst. in the Saloon of the Royal Hotel. Dr. William Browne, President of the Society, occupied the chair, and there was a large attendance. Dr. Benjamin Bill read the annual report, which showed the Society to be in a flourishing state.

LARBERT INSTITUTION FOR IMBECILE CHILDREN.—The annual meeting of the Aberdeen auxiliary of this institution was held in the Music Hall Buildings on Wednesday of last week. Professor Traill presided. Through the exertions of a number of lady collectors a considerable sum is sent annually from Aberdeen, the contributions for the past year having been £154. Mr. Pitch, the Secretary, also stated that he had received a legacy of £1,000, through Mr. Francis Edmund, for the purpose of forming a fund which would meet all outside expenses, and allow the annual subscriptions to be devoted solely to the maintenance and education of the children sent to the institution.

INVERNESS.—Casts of diphtheria have appeared in several parts of the town, and the Provost and Superintendent of sanitary affairs have taken steps to have the drains flushed *at least once per year.*

EDINBURGH ROYAL PHYSICAL SOCIETY.—On the 19th inst. the first meeting of the 109th session of this Society took place at 5 St. Andrew Square, Dr. H. Ramsay Traquair, President, in the chair. After a number of donations to the library had been intimated, the chairman delivered the customary opening address, in the outset of which he dilated to the members on the fact that, old as the Physical Society was, being the oldest in Edinburgh, it did not at present show any signs of disease or decay. It now, indeed, displayed a greater amount of vigour and of health than the Society had done for many years. The roll at present mustered 229 members, and as the forehcoming volume of the "Transactions" would show, a goodly number of members were devoting themselves to practical work. After noting that much of the prosperity of the Society was due to the unflagging energy and zeal of the secretary (Mr. Robert Gray), Dr. Traquair went on to remark that during the past year death had taken from amongst them more than one of their prominent members, mentioning especially Dr. Macbean, who had been twice President of the Society, the late Treasurer; and Professor Page, Newcastle, one of the corresponding members of the Society. Dr. Traquair afterwards sketched "The History of Scottish Fossil Ichthyology." At the close, on the motion of Professer Duns, a vote of thanks was awarded to the President for his address.

GLASGOW.—SUDDEN DEATH.—On Thursday last a woman, when passing along Hill Street, Garnet Hill, took suddenly unwell. A boy who was passing asked what was wrong, when she replied that she had taken a dose of laudanum. The assistance of Dr. Foulis was at once secured, and he ordered her removal to the Western Infirmary in a cab, but before the vehicle reached its destination the woman was dead. The deceased seemed to have been a washerwoman, and to be aged about 50 years.

GLASGOW UNIVERSITY MEDICO-CHIRURGICAL SOCIETY.—The city has been extensively placarded with bills announcing that this Society was to have been opened by an address from Professor McCall Anderson, "On the Treatment of Consumption by High Altitudes." If the public are not expected to att nd this Society on the opening night, it might be a subject of legitimate wonder what the object of so placarding the city is.

THE LATE ALEXANDER DONALDSON, SURGEON.—By the will of this gentleman, who died recently at Mount Florida, the sum of £50 is bequeathed to the Royal Infirmary of Glasgow.

Correspondence.

FOREIGN BODIES IN THE EAR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Having with pleasure read the really good observations under the above heading from the pen of John B. Story, Surgeon to St. Mark's Ophthalmic Hospital, in your issue of the 5th inst., I would feel much obliged if you would be so kind as to insert the following cases, which occurred in my practice as a dispensary medical officer, and were at once brought to my memory on reading Mr. Story's letter.

About seven years ago, being then in charge of the Crossakiel Dispensary District, a man about forty-five years of age came to the dispensary complaining of great uneasiness and deafness in right ear, the latter symptom occurring suddenly. I asked him to what cause did he attribute those symptoms. He could tell me no more than that he had been threshing oats in a barn; that perhaps the noise of the occupation, or some dust getting into the ear, might have caused them. I carefully examined the meatus, and detected a foreign body, and made every attempt to dislodge it with scoop, bent probes, &c., but all to no purpose, until I syringed the meatus out with tepid water, when a large grain of oat was carried out by the stream of water from the syringe, and the man was cured.

On the 6th April, 1876, a girl, æt. five years, named Mary Keenan, daughter of a pensioner who received a gunshot wound in the Crimean war, residing in this Delvin Dispensary District, was brought to the Craddenstown Dispensary Station with a piece of slate pencil in her ear. Having no syringe at hand, and being four miles distant from my house, I made some attempts to extract the foreign body with probes, directors, &c., but could not succeed in doing any good, but very nearly inflicted much harm. I asked the father, who came with the child, to bring her to Delvin, where I resided at the time. He did so on the evening of the same day. I syringed the ear, throwing the tepid water in a small but steady stream behind the foreign body for a short time, when the piece of slate pencil was discharged, and the girl was cured.

I would not advise any anxiousness in the use of hair-pins, or other pins, for extraction of foreign bodies from the ears.

Yours faithfully,

WILLIAM CARLETON, M.B. T.C.D., &c.

Delvin, 6th November, 1879.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read Dr. Story's observations condemning instrumental interference in the case of foreign bodies in the ear, and I would like to say a word in defence thereof.

I am not an aurist, only a country practitioner, possessing that inestimable advantage, a county infirmary, which confers a wide field of observation, scarcely a day passing that one or more aural cases do not present themselves.

With Dr. Story's first and second rules, viz., see the foreign body and syringe the ear, every one must concur; they are, or at least ought to be, taught to every first year's student.

Illumination is undoubtedly necessary, and is very easily procured by a little hand-lamp, which I lately got from Fannin.

Syringing is the next step, and should be done as Dr. Story describes; but when it fails, I cannot agree with Dr. Story's third rule, "Leave the foreign body where it is." I have no doubt that, as he says, patients have been killed by attempts to remove foreign bodies, which were otherwise perfectly harmless; but it is *impossible* to persuade patients that the latter is the case.

I have *generally* found the syringe successful, but when it

Digitized by Google

fails I always use instruments, and have never yet found them harmful; and I have never failed with them except in the one case which I mentioned in my note on the use of the hairpin.

I advocate the use of instruments, therefore, for the following reasons :—

1. If the foreign body be left in the ear, the patient, "disregarding the assurance that it is perfectly harmless," will root at it, thus causing irritation, probably an abscess, possibly worse.

2. If left quiescent, cerumen will congregate round it, and cause deafness.

3. The patient and anxious friends will vote you a botch, dismiss you, and call in another doctor.

Yours, &c.,

EDWARD A. RAWSON.

Nov. 7, 1879. Surgeon Carlow County Infirmary.

SUPERANNUATION FOR POOR-LAW MEDICAL OFFICERS—A SUGGESTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—At present there is a modified form of superannuation available by Poor-law medical officers, but as it depends on the caprice of the guardians, it is imperfect. The justice of granting such an allowance hardly admits of argument, though we cannot convince the authorities on this point. The Poor-law Medical Service is a most important one, and as generally Poor-law medical appointments are held by the real hard-working portion of the profession, provision for old age or for sickness is a most important consideration. I fear that Government, whether Conservative or Liberal, will be slow to move in this matter, though the Poor-law Medical Officers' Association need not nevertheless desist in their efforts.

I presume there are some thousands engaged in the Poor-law Medical Service, and I offer a suggestion, for what it is worth, for the consideration of the leaders in the department: Would it be possible to form a Poor-law superannuation fund by the members themselves, so that for a certain fixed rate of payment an annuity might be granted after a certain number of years of service? This scheme would require the support of the majority of Poor-law practitioners, and would of course require careful working out in all its details to make it a financial success. I shall be glad to hear the opinion of some of our Poor-law medical officers anent this suggestion.

Yours, &c.,

T. M. DOLAN, F.R.C.S.ED.

Horton House, Halifax.

[A scheme for providing a pension for the widows and orphans of Irish Poor-law medical officers was elaborated some years since by Dr. Archibald Jacob, of Dublin, at the suggestion of Dr. Darby, of Bray. It was Dr. Jacob's calculation that, if these officers would submit to a deduction of 14s. per quarter from their salaries they might secure a yearly pension of £10 for their widow for life, and £10 for each child up to 21 years of age, in case of survivorship. The scheme was not realised because Mr. Hancock, the actuary of the National Insurance Co. of Ireland, was of opinion that it could not be carried out unless it were, for the present, restricted to the new entrants of the service, and unless it were made compulsory on them. As to a superannuation fund, we hardly think that Irish Poor-law medical officers would submit to a deduction from salary in order to obtain that which the State is morally bound to provide without deduction.—ED. M. P. & C.]

THE NEW WARRANT.—INDIAN PAY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I notice that the Regulations for the A. M. D. published recently make no mention of Indian pay. I saw, some time ago, a letter in one of the medical journals warning men against the trick which the Government played when the warrant of 1876 came out—viz., whilst promising a large increase in the home pay, to keep the Indian pay almost the same as before. I trust that the new warrant (which seems a good one so far) will not be spoiled in the same manner, and that the authorities will see their way to publish the scale of Indian pay for the A. M. D. before December.

Another way in which candidates are deceived is this :—In the Regulations the rupee is stated to be worth 2s.; now it has not been worth 2s. for years. I see in the *Lancet* of Nov. 15, by a letter over the signature of "India," that in 1876 the rupee was worth 1s. 6½d. In that very year the warrant was issued in which the rupee is valued at 2s.! "India" also says—"The rate of exchange in the market this day (Oct. 16) is 1s. 8d. the rupee, but how long this may remain so is unknown." "A Bengal Civil Surgeon," in the same issue of the *Lancet*, bears out "India" as to the value of the rupee. Now it is very probable, owing to the war, that the rupee will decrease even more in value. Intending candidates would do well to remember that within eight or ten months after leaving Netley they will be ordered to India for at least five years. They may then have five years at home, or perhaps less. In any case nearly half of their service will be Indian. The exceptional perils which medical officers have to face in the combat with disease is well shown by the frightful mortality amongst surgeons serving with regiments in Afghanistan. Taking all these things into consideration, I think you will agree with me, Sir, that the Indian pay should be liberal, and, if paid in Indian money, that the rupee should be reckoned at its proper market value.

Truly yours,

Nov. 19th. DUBLIN STUDENT.

THE MICROSCOPICAL SOCIETY'S TRANSACTIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Under the above heading, in your issue of Nov. 19th, Mr. Wenham states that he has been driven to retire from the R. M. Society by the "barefaced" conduct of the Society's officers, and the "twaddle" with which its journal is now filled; and for the purpose of illustrating the treatment to which he has been subjected, he goes on to describe what he calls the "mendacity" of a particular footnote, for the publication of which I am responsible. This pointing of Mr. Wenham's moral I am obliged to answer in person, and though it would be impertinent and superfluous for me to defend either the Society's officers or its journal, I should be ungrateful did I pass on without thanking our President for the unbroken dignity and kindness with which he presides over our meetings, and the honorary Editor of our journal for the skill and devotion by means of which he has raised the journal of the Royal Microscopical Society to a position which no other microscopical journal has ever obtained.

I sympathise with Mr. Wenham for the rebuffs which he has experienced of late, but I think that the council had no alternative other than to curtail his meanderings on the subject of "Angle of Aperture," the theory of that question being clear to everyone but Mr. Wenham, and the facts being open to physical demonstration by any competent microscopist. What Mr. Wenham's friends hope he will do is to stick to his optical lathe, where only three men that I know of can excel him, *i.e.*, Thomas H. Powell, R. B. Tolles, and Carl Zeiss.

My letter from *Nature*, of July 11, 1878, was, I am sure, intended to be fairly quoted, but reference back will show that the last sentence—a cardinal one—has been omitted. The omitted sentence runs thus :—"I ought to add that until the construction of my illuminator by Messrs Powell and Lealand, the device had never come into practical use, and that, so far as I can learn, no reference to it exists in any optician's catalogue or text-book on the microscope." Not only do the works of Beale, Carpenter, Hogg, and other English authors ignore Mr. Wenham's absurd parabolo d, but I find no mention of it in the great French work by Robin. The late editor of the *Monthly Microscopical Journal* considered my paraboloid as new, and the editor of the *Journal de Micrographie* for August, 1878, also describes it as a new invention.

As to the footnote in the *Quekett Journal* of April, 1878, it was suggested by a competent microscopical friend of Mr. Wenham's—Mr. John Mayall—who sent me, as what in his judgment should be published, the following, which I now transcribe from Mr. Mayall's MS.:—

"As to the question of priority between Mr. Wenham and myself in the design of the immersion paraboloid, it needs

Digitized by Google

only that I observe the paraboloid suggested by Mr. Wenham had not the same purpose in view as that obtained by my device; the construction was not like mine nor was the adaptation as a piece of useful accessory apparatus in the slightest degree resembling. In fact, Mr. Wenham's suggestions came to practically *nil*, even in his own hands. I regard Mr. Wenham's device of twenty years ago as of no practical value—a merely empirical experiment having no definite purpose."

This I condensed as follows:—

"As between Mr. Wenham and myself, I need only to observe that the paraboloid described by Mr. Wenham was not like mine, either in its formula or its effects, and that the method of working and applying the two instruments as accessories to the microscope do not in the least resemble each other."

So much for the "mendacity" of the footnote. I still think its terms fair and accurate.

Anyone versed in physical optics and in the properties of the parabola will see, on referring to Mr. Wenham's old paper, that his experimental paraboloid was so cut off that it never could have done what is done by mine, as described in the *Journal de Micrographie*, and in Dr. Beale's new edition, at page 28, as follows:—

"The formula of Dr. Edmunds's immersion paraboloid is such that all the parallel rays of light entering the base are made to converge by total internal reflection upon the object placed on the slide, and the plane top is at such point below the focus of the object-glass as to allow exactly for the thickness of the slide and connecting film of glycerine. With the usual substage movements, the focussing or centering of this paraboloid can be varied as readily as that of the objective, &c." I have only to add that Mr. Wenham's paraboloid was about as large as the top of the little finger, while mine is an inch and a-quarter in diameter.

Mr. Wenham's paraboloid was, I should imagine, never duplicated, and it is not even referred to in the catalogue of the great optical firm to which he belongs. Already large numbers of mine have been made by Messrs. Powell and Lealand, and the instrument has come into general use.

I am quite prepared to demonstrate, either geometrically or physically, that Mr. Wenham's paraboloid will not do what is accomplished by mine, but I have too much regard for your space to ask you to admit further argument. The facts will be seen at once by any competent reader who will peruse Mr. Wenham's paper.

Yours, &c.,

JAMES EDMUNDS, M.D.

8 Grafton Street, Piccadilly, W.
November 24th.

Literary Notes and Gossip.

WE notice a useful publication, undertaken by the Kieff Naturalists' Society, being a complete index of all works on Medicine, Natural Science, and Mathematics, that have appeared in Russia during the years 1872—1877.

* * *

WE learn that the library of the learned Societies in France is now in course of removal from the Ministry of Public Instruction to the Institute. It contains about 15,000 volumes of the Proceedings of all the learned Societies of France and her Colonies.

* * *

Le Journal de Pharmacie et de Chimie contains an article from Prof. Pasteur, in which he declares his conviction, based on experiment, that the phenomena of fermentation find their analogies in those which take place in the animal economy.

* * *

BY a resolution of the Treasury, the annual grant to the British Museum for the purchase of books is to be reduced. Originally put at £3,000, this has been reduced by the Museum officials' efforts to £2,600; but this cannot be regarded as other than a very serious loss on the total sum hitherto allowed, viz., £6,000.

* * *

York House Papers is the title of a new weekly paper. The first numbers show a spirited endeavour on the part of the promoters to fill a want existing for a good penny paper on social subjects, well and respectably written. We detect some imperfections, however, but time will doubtless remove them. It is well-printed, and presents a neat and attractive appearance.

* * *

THE study of Chinese is progressing. Harvard now follows the home example, and has founded a chair of Chinese. May we hope that the success attending Sir Thomas Wade's efforts to promote the study of the Celestial language will result in our obtaining some satisfactory information about, and translations of, the very ancient and much-vaunted medical works of the Chinese philosophers?

* * *

WE understand that our contemporary, the *Guy's Hospital Gazette*, has been placed under the inquisitorial control of the Treasurer to the Hospital, and that nothing is permitted to enter its pages without first undergoing supervision. We cannot too strongly condemn this attempt to coerce student opinion, and for the sake of Guy's and its traditions, we trust the decision may be withdrawn.

* * *

"ZIEMSSEN'S Encyclopædia of Medicine" has been largely taken in by English subscribers. It is a voluminous work. We learn from Vienna that another Encyclopædia is about to be published by MM. Urban and Schwarzenberg, No. 4 Maximilien Strasse, under the direction of Dr. Albert Eulenberg, Professor at the University of Griefswald, assisted by ninety collaborateurs. It will be completed in ten volumes, and will appear in fasciculi, price 1 fr. 90 c., and the complete work will cost about £8.

* * *

THE American Treasury has adopted a distinctive paper, different from that now in use, for all its monetary obligations and securities. One of its distinctive features is the introduction of coloured silk threads into the body of the paper while in the process of manufacture, in combination with a distributed silk fibre of different colours. According to the American statutes "anyone who has or retains in his control or possession any similar paper is subject to a fine of not more than £1,000, or to imprisonment with hard labour for not more than fifteen years or to both."

* * *

AN interesting publication on human longevity, by the Austrian Director of Administrative Statistics, has lately appeared in Vienna, the recent censuses in various European states furnishing the necessary material. It appears that of 102,831 individuals in the larger states, who had passed 90 years of age, there were 60,303 women and 42,528 men. The greater longevity of the feminine sex appears still more distinctly in the proportions of centenarians; in Italy, *e.g.*, there are 241 centenarian females to 141 males; in Austria, 229 females to 183 males; in Hungary, 526 females to 524 males, &c.

* * *

THE Wyld-Richardson correspondence again crops up in the current number of the "Monthly Homœopathic Review." The vitality of error is very great. We had hoped that the crude conception had been stamped out of the brain of Dr. Richardson, and that this ghost was laid in peace. Dr. Wyld's letter has one good effect, however, which the editors of the M. H. R. acknowledge in the following words: "That letter gave a sort of shock to the general confidence in the reality of our faith in homœopathy, which has even now not been recovered from." In the same number there is an amusing article on Dr. Andrew Clark and the present state of therapeutics; we cannot treat it *au serieux*.

* * *

WE have received the "Physicians' and Surgeons' Visiting List, Diary, Almanac, and book of engagements for 1880," issued by Messrs. John Smith and Co., and can heartily congratulate the publishers on the elegant and handy appearance of the work. Besides the essentials of a diary and reminder, the book contains much useful information in an easily seen form. The "Pharmacopœial Companion" is well arranged, and sufficiently complete for practical use; the whole volume is just such a pocket-companion as the working practitioner needs to aid him in his daily routine. We would suggest that in their next issue they would insert a table of metric weights and measures.

* * *

MEDICAL men have, during the past few years, found a lucrative field for literary work in our high-class monthlies and quarterlies. Medical subjects are interesting. We have received some letters on this subject. If Dr. Great-Gun is allowed to write an article in the *XIX. Century*, on some

Digitized by Google

edical subject, and to append his name, why should not r. Small-Gun write to the *Village Gazette*, and sign his ame to some medical paper? What an advertisement it ould be for him. But an outcry would be at once raised gainst such a procedure by the local professional men. There oes not seem at first sight to be any flagrant violation of pro-ssional customs in writing for lay journals. There is this anger. It may be abused, and become another method of in-irect public advertising.

* * *

Mr. Edward Stanford publishes a work that is to us a narvel and a wonder. It bears the title "Instructive Picture-book, the Human Body, an Atlas of Anatomy." An in-tructive picture-book it certainly is; and the authoress, Mrs. Fenwick Miller, must have been sorely taxed to get ogether the terrible figures that are depicted. We can do no more than draw attention to the work here, and pity Mrs. Miller the dreadful sights she must have witnessed, if she eally has seen a platysma muscle half an inch thick, or a ubject in which the small intestine (carefully measured on he plate) was no more than two and a-half times the length of the large. The picture of the arteries of the head is, how-ever, most carefully *imagined*; the greatest possible pains having been taken to prevent the idea being gained from its study, that any anastomoses of neighbouring twigs exist; but it may be doubted whether the novel view of their distribution, therein set forth, is calculated to improve away the impressions left by dissections. The work is calculated to do something in this direction, and if it has been published with the object of misleading anyone who takes it up, we can so far congratulate the authoress and publisher on the success of their endeavours.

* * *

The *Lancet* is virtuously indignant again (fortunately it does not occur oftener than once a week) because newspapers will persist in copying paragraphs from the medical journals. Dr. Pearse, of Plymouth, a few weeks since published in the *Medical Press and Circular* some climatic notes on Devonshire, and valuable suggestions on the Treatment of Consumption. The editor of the *Plymouth Mercury*, deeming these of sufficient importance and intereat to his readers, transferred them to his columns, whereupon the *Lancet* is angry with the offending editor or Dr. Pearse (being uncertain as to the deliquent) at such a serious breach of "Newspaper Therapeutics." The fact is, our contemporary's gossip has so long monopolised the columns of the lay press, that its indignation at seeing another medical journal quoted, culminates in a violent fit of jealousy. But in order that our sins may not be visited upon poor Dr. Pearse, we are prone to admit that the blame is attributable solely to our energetic publisher, who unfortunately believes in that obsolete maxim that "what is sauce for the goose is sauce for the gander." The *Lancet* goose having fattened so many years on newspaper quotations, he is bent upon trying the fare on the *Medical Press* gander; and thinks if it is not wrong for the *Lancet* to send slips to the newspapers, *it ought not* to be so for the *Medical Press*.

* * *

New Books and New Editions.—The following have been received for review since the publication of our last list, November 5th:—"A Text-book of Physiology," by M. Foster, M.D., F.R.S., third edition. "The Treatment of Fits," by J. H. Waters, M.D. "The Pocket Gray or Anatomist's Vade Mecum." "Practical Surgery," by J. Ewing Mears, M.D. "The Student's Guide to Diseases of the Eye," by E. Nettleship, F.R.C.S. "Smith's Visiting List for 1880." "Functional Derangements of the Liver," second edition, by the late Dr. Murchison. "Transactions of the Clinical Society," vol. xii. "Memorial Oration in honour of Ephraim McDowell, M.D. "The Carmichael First Prize Essay," 1879, by Walter Rivington, F.R.C.S. "The Carmichael Second Prize Essay," 1879, by Thomas Laffan, L.K.Q.C.P.

Metropolitan Hospital Sunday Fund.—The annual meeting of the Council of this Fund was held on Monday at the Mansion House. Sir Francis Lycett presided, in the unavoidable absence of the Lord Mayor. The Council in their report stated that the seventh year of the operation of the Fund had realised £26,501, as compared with £24,904 in 1878, notwithstanding the unusual financial depression of the times, and a very wet Hospital Sunday. The number of contributing congregations had also exceeded that of the previous year. The Committee of Distribution recommended a sum of £22,884 to 81 hospitals, and £2,157 to 46 dispensaries. One per cent. of the gross receipts, £260, had been set aside for the purchase of surgical appliances. The report was adopted unanimously.

Royal College of Surgeons of England.—The following gentlemen, having passed the required examination for the diploma, were duly admitted members of the College at a meeting of the Court of Examiners on the 17th inst.:—

Bowe, Francis, L.S.A.
Cama, Rastamji Hormasji, L.M.
Fellowes, H. T. A. Butler, L.S.A.
Gabe, John, L.S.A.
Harrison, James, L.S.A.
Mead, George Owen, L.R.C.P.Ed.
Murray, Henry Walker, M.B.Dub.
Parsons, Herbert Flower, L.S.A.
Pearce, John Puckey, L.S.A.
Purkess, Arthur, M.B. Aberd.
Sanders, John William, L.S.A.
Veale, William Edward, L.S.A.
Walker, John Sydenham, L.S.A.
Whiteley, George W., L.R.C.P.Ed.

The following passed on the 18th inst.:—

Ansted, H. L. Petrel.
Benthall, A. Elliott.
Betts, E. George, L.S.A.
Cleaver, J. C. Carleton.
Davies, J. M. Lloyd, L.R.C.P.Ed.
Farrar, R. Thompson.
Fialho, J. Henrique, L.R.C.P.Ed.
Gwynn, R. Henry, L.R.C.P.Ed.
Haycroft, C. Henry, L.S.A.
Hill, H. Gardiner.
Howell, T. A. Ives, L.R.C.P.Lond.
Hudson, T. Joseph.
Jefferson, A. John, L.S.A.
Jones, Charles, M. Handfield.
Lawford, J. Bowring, M.D.
Leibstein, H. John, L.S.A.
Luckman, E. Llewellyn.
Maberly, H. Edward.
Maddick, E. Distin, L.R.C.P.Ed.
Michell, J. Thomas, M.D. Aberd.
Morgan, James, L.R.C.P.Ed.
Parker, W. Rushton.
Penruddocke, Charles, Bristol.
Preston, H. F., M.B. & C.M. Aber.
Priest, J. Damer, L.S.A.
Pilkington, G., L.R.C.P.Ed.
Smith, Sydney, L.R.C.P. Lond.
Steele, Richard, L.R.C.P.Ed.
Sutcliffe, John.
Swindells, J. Alum.
Tarleton, Paul, L.R.C.P.Ed.
Taylor, David, M.D. Dub.
Thomson, G. J. Crawford, L.S.A.
Vinrace, F. Coulson.
Willoughby, J. F. Digby.
Wright, C. St. John, L.S.A.

Rentoul, R. Reid, L.R.C.P.Ed.
Smyth, Sydney.
Swabey, Louis W.

Dence *v.* Mason.—A question of some little importance indirectly to the profession, was decided last week in the Court of Appeal in the case of Dence *v.* Mason. Both parties were originally partners in the firm of Brand and Co., manufacturers of the meat essences for invalids, so largely prescribed by the profession. The defendant Mason has not however for a long time been connected with the firm, and has no right to use the name of Brand; but contrary to agreements and decisions of one of the law courts has made and sold essences, which were colourable imitations of Messrs. Brand and Company's. The defendant has already undergone fine and imprisonment for contempt of the Vice-Chancellor's decision, from which this was an appeal. After hearing arguments on both sides, their Lordships confirmed the injunction of the Vice-Chancellor, whereby the defendant is prohibited in perpetuity from using in any way the name of Brand as applied to invalid specialities.

NOTICES TO CORRESPONDENTS.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the Medical Press and Circular, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

Dr. O'Flanagan.—"Cases of Tetanus successfully Treated" received, and will appear in an early number.

A Statistician estimates the present population of the globe at 1,421,000,000, divided thus:—Europe, 309,000,000; Asia, 834,000,000; Africa, 199,000,000; Oceanic, 4,000,000; America, 85,000,000. It has been calculated from the mortality tables of known countries that the annual number of deaths throughout the world is 35,963,350, or that, in other words, 97,760 persons die each day. On the other hand, the balance of population is more than kept up by births at the rate of 104,800 per day. Seventy new lives are ushered in every minute of the twenty-four hours.

ALLYROAN DISPENSARY ELECTION.

A SPECIAL meeting of this committee was held to elect ical officer for the district, the proceedings of the meeting being nilled by the Local Government owing to informality. There were two candidates, Blunden and Dr. Coyne. A division was called with following result—for Dr. Blunden 7; for Dr. Coyne 5.

MONAGHAN BOARD OF GUARDIANS.

DR. ROSS entered the board-room and handed a letter of resignation of the office of medical officer of Monaghan Workhouse, which he had held for the past seven and a half years.

The Chairman said he was very sorry to receive this communication, for he thought Mr. Ross was active, attentive, gifted, and energetic, and he believed above all things he was kind and considerate toward those who were placed under his care. He was quite taken by surprise, for no person knew anything, so far as he had heard, of Dr. Ross's intention to resign his post. Could anyone have given him offence? or was he about to leave Monaghan?

Mr. J. M. Ross had heard nothing at all about his intention to resign.

The Chairman—He seems to be a man who keeps his own counsel.

Mr. Murray—Apparently.

Dr. Ross's resignation was accepted with expressions of regret for the loss of his services.

MOUNTMELLICK UNION.

EXAMINATION OF LUNATICS.

MR. COBBE said there was a letter received from Mr. Turpin last board day relative to doctors' fees for the examination of lunatics. The Act of Parliament specifies that a doctor for examining a lunatic is to get a "reasonable fee." He (Mr. Cobbe) held that that reasonable fee meant his (the doctor's) usual fee, and therefore he would propose—"That this board is not satisfied with Mr. Turpin's definition of the Act relative to the doctors' fees for the examination of dangerous lunatics. This board considers that the reasonable fee to be paid the doctor is his usual fee of one guinea, and that unless he incurs expenses outside his so examining the patient his fee should be only his ordinary fee, and this board are determined to pay no more."

DR. RICE'S CLAIM.

The following letter was read:—

"To Board of Guardians of Mountmellick Union.
"Mountmellick, 14th November, 1879.

"GENTLEMEN,—I have received instructions from Dr. Rice to apply to you for payment of £16 4s., due to him for discharging the duties of medical officer at the Mountmellick workhouse and dispensary during Dr. Clarke's illness, for five weeks ending 16th August last. Your early attention will oblige.

"Your obedient servant,
"JOHN ALEXANDER FITZGERALD."

The Clerk—Dr. Rice was offered £14 2s., which he refused. Dr. Clarke told me this day that he offered to pay him the balance, but he would not take it from him. Dr. Rice said if he had known at first he was only to be allowed three guineas a week he would not have accepted it; but I have proof here that he was well aware of the salary allowed, and that he did accept it.

The Chairman—I think he ought not to be offered the cheque again; if he wants it let him ask for it.

TANDRAGEE DISPENSARY.

A MEETING of the committee was held to appoint a medical officer in succession to Dr. Hamilton, who recently resigned. There were two candidates for the situation—Dr. Taylor and Dr. Wallace. For Dr. Wallace, 6; for Dr. Taylor, 10. The Chairman accordingly declared Dr. Taylor elected by a majority of four votes.

FOREIGN GRADUATES.—The annual meeting of this Association will be held to-night in London at the Charing Cross Hotel at 8 o'clock.

PLEXIMETERS—FEVER SWEATS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Please inform me through the medium of the MEDICAL PRESS AND CIRCULAR which of the following percussors would you recommend me—viz., Haller's Percussor, King's ditto Cone, Bennett's Pleximeter and Hammer, or Sib on's Spring Plessimeter, which consists of a round pad of india-rubber fixed to the end of an axis, and striking on a plate of ivory. Also the best recognised treatment in the hot and sweating stages of fevers.

Yours truly,
PERCUSSOR.

[1. We have never used in actual serious work any of the three named percussors. 2. We presume our correspondent means the treatment of sweating as a symptom in fever; for example, in the hectic of phthisis, undoubtedly the most practical and scientific treatment for sweating as a symptom in fever is small doses of *atropia*. It can be given in pill in doses of one-eightieth to one-fortieth of a grain rubbed up with sugar of milk, or in mixture or draught corresponding doses of one and a-half to three minims of the Pharmacopœial liquor atropiæ. This should be given about an hour before sweating usually commences, so as to secure, through its stimulating action on the sympathetic system, the partial contraction of the arterioles supplying the sweat glands, and the consequent diminution of their supply of blood. If this should fail, three to five grains of Dover's powder given once or twice in the night is an excellent anhydrotic—ED.]

THE LATE MR. J. C. COPLAND.

AT a preliminary meeting held at the house of Dr. Semple, on the 29th ult., it was resolved to raise a subscription to be presented to the widow of the late Mr. James Charlesworth Copland. Mr. Copland was the author of the abbreviated edition of the well-known *Medical Cyclopædia* of Dr. James Copland, and was a nephew of that distinguished physician and lexicographer. He served as a surgeon in the Crimean war: he was afterwards a member of the Court of Examiners of the Society of Apothecaries, and was rapidly making a name in medical literature when he was attacked with an intestinal affection; and, after a few hours' illness, was cut off in the prime of life on the 18th of September last, leaving a widow and five children almost unprovided for. Dr. Semple was requested to act as treasurer, and Mr. Arthur Norton as secretary.

The following is the list of subscriptions at present received on behalf of the above fund:—

Dr. Stocker	£10	0	0
Dr. A. Norton	10	10	0
A. Norton, Esq., F.R.C.S.	5	5	0
"As ye would, so do ye unto them" ..	5	5	0
Thomas Smith, Esq., F.R.C.S.	5	5	0
A Friend	5	5	0
Editors of the *Medical Press and Circular* ..	5	5	0
H. Sewill, Esq.	3	3	0
Dr. Semple	2	2	0
Dr. Burgess	2	2	0
Dr. Thorowgood	2	2	0
Dr. Ward	2	2	0
Dr. Fowler	2	2	0
Dr. Taylor	2	2	0
G. Bury, Esq., F.R.C.S.	2	2	0
H. Bullock, Esq., F.R.C.S.	2	2	0
T. R. Wheeler, Esq., F.R.C.S.	2	2	0
Dr. Begley	2	0	0
J. Roche Lynch, Esq.	2	2	0
W. Ling, Esq., Brightlingsea	2	2	0
Dr. Randall	1	1	0
Dr. Lavies	1	1	0
Dr. G. Savage	1	1	0
Dr. Harvey Owen	1	1	0
Henry Stear, Esq., Saffron Hill	1	1	0
J. T. Clover, F.R.C.S. .. .	1	1	0
Dr. G. C. Dale, Tooting	1	1	0
G. Field, Esq.	1	1	0

Subscriptions may be forwarded to the Treasurer, Dr. Semple, 8 Torrington Square, W.C.; or to the Secretary, Arthur Norton, Esq., 6 Wimpole Street, Cavendish Square, W.

HUNTERIAN SOCIETY.—This evening (Wednesday), at 8, Mr. Rivington, "On some Cases of Aneurism."—Dr. Stephen Mackenzie, "On Tumours of the Cerebellum"

PSEUDO-MEDICAL DEGREES.—As *apropos* to the above subject, on which there has been some discussion of late, a valued correspondent sends us the following amusing anecdote:—"When, a few years since, the *degrees* of the University of St. Andrew's were purchasable by any comer at so much per head, a certain minister, who deemed that his ministrations would be more acceptable and more useful if he possessed what the doctors call *doctor's shat*, put £15 in his purse and went to St. Andrew's to purchase for himself a degree. His manservant accompanied him, and was present when his master was admitted to the long-desired honour On his return, *the Doctor* sent for his servant, and addressed him somewhat as follows: 'Noo, Saunders, ye'll aye be sure to ca' me *the Doctor*; and gin onybody spier at you aboot me, ye'll be aye sure to say 'the *Doctor's* in his study,' or 'the *Doctor's* engaged,' or 'the *Doctor* will see you in a crack.' 'That a' depends,' was the reply, 'on whether ye ca' me the *Doctor*, too.' (The reverend doctor started). 'Aye, it's just so,' continued the other; 'for when I fand that it cost nae leetle, I e'en got a diploma mysel. Sae ye'll just be guid enouch to say, '*Doctor*, put on some coals,' or '*Doctor*, bring the whisky and hot water;' and gin onybody spiers at ye aboot me, ye'll be sure to say, 'the *Doctor's* in the pantry" or 'the *Doctor's* diggin' potatoes,' as the case may be."

CLINICAL SOCIETY OF LONDON.—On Friday, Nov. 28, at 8½ p.m., Mr. W. J. Tyson (Folkestone), "On a Case of Traumatic Aneurism of the Scalp."—Mr. Croft, "On a Case of Excision of both Hip-joints for Symmetrical Femoral Necrosis; Operations Antiseptic; result successful."—Dr. Goodhart, "On a Case of Rheumatism treated by Salicylate of Soda, terminating fatally."

DR. WILSON.—You will find the subject ably handled in Mr. Rivington's Hunterian Oration, recently published in pamphlet form.

A BOOKWORM—The third edition is just out; the work has had a rapid sale, but not more than it merits.

POOR-LAW MEDICAL UNION.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—The army medical officers have gained their object by uniting. Why cannot the Poor-law Service obtain what they want? The answer is simply because they do not stick together. I wish they would take to heart the following fable from Swift:—

Observe the dying fathers speak,
"Try lads! can you this bundle break?"
Then bids the youngest of the six
Take up a well-bound heap of sticks;
They thought it was an old man's maggot,
And strove by turns to break the faggot.
In vain; the complicated wands
Were much too strong for all their hands.
"See," said the Sire, "how soon 'tis done,"
Then took and broke them one by one.
"So strong you'll be, in friendship ty'ed,"
"So quickly broke if you divide;"
"Keep close then, boys! and never quarrel,"
Here ends the fable and the moral.

Yours faithfully,
Burnley, Nov. 20, 1879. VIS UNITA FORTIOR.

VACANCIES.

Bristol Royal Infirmary.—House Surgeon. Salary, £100, with board, &c. Applications to the Secretary on or before Dec. 1.

Ellenderry Union, Johnstown Dispensary.—Medical Officer. Salary, £120, with fees, and £15 as Medical Officer of Health. Election Nov. 27.

Great Northern Hospital, London.—Two Physicians. Honorary. Applications to the Secretary on or before Dec. 4.

Hospital for Children, Great Ormond Street, London.—House Surgeon. Salary, £50, with board, &c. Applications to the Secretary on or before Nov. 27.

Monaghan County Fever Hospital.—Medical Officer. Salary, £50. Election, Dec. 3.

APPOINTMENTS.

BEATTIE, J. A., L.K.Q.C.P.I., L.R.C.S.I., Assistant Medical Officer, Hospital for the Insane, Parramatta, New South Wales.

BLAXLAND, H., L.R.C.P.L., Assistant Medical Officer, Hospital for the Insane, Gladesville, New South Wales.

BLUNDEN, A., L. & L.M.R.C.P.Ed., L.R.C.S.Ed., Medical Officer to the Ballyroan Dispensary, Abbeyleix Union.

CARRE, F., L.K.Q.C.P.I. & L.M., F.R.C.S.I., Certifying Factory Surgeon for the District of Letterkenny, co. Donegal.

EDMUNDS, R., L.R.C.P.Ed. & L.M., M.R.C.S.E., Medical Officer for the Pontypool District of the Pontypool Union.

FITZGIBBON, H., M.D., M.Ch. Univ. Dub. Medical Officer to the General Post Office, Dublin.

HENRY, J., M.D., L.R.C.S.I., Medical Officer of Health for the Rochdale Urban Sanitary District.

MACALISTER, A., M.D., Professor of Anatomy and Surgery in the School of Physic, University of Dublin.

MOBLEY, E. J., M.R.C.S.E., L.R.C.P.L., a Resident Medical Officer to the General Infirmary, Northampton.

NEWSHOLME, A., M.R.C.S., Assistant House Surgeon to St. Thomas's Hospital.

SHEPPARD, C. E., M.B. Lond., L.R.C.P., M.R.C.S., Resident Accoucheur to St. Thomas's Hospital.

SHINKWIN, T. C., M.D., M.R.C.S.E., Lecturer in Surgery to Queen's College, Cork.

Births.

BLAKE.—On Nov. 16, at Ravensdale, Dundalk, the wife of R. Mariay Blake, L.R.C.S.I., of a son, who only survived his birth a few hours.

MACDOWELL.—On Nov. 19, at Baltinglass, co. Wicklow, the wife of Francis Victor MacDowell, L.R.C.S.I., of a son.

MCCLURE.—On Nov. 19, at Worle, Somersetshire, the wife of Thomas McClure, M.D., F.R.C.S.I., of a daughter.

M'FARLAND.—On Nov. 17, at Malahide, the wife of Surgeon-Major F. E. M'Farlane, A.M.D., of a daughter.

NORE.—On Nov. 21, at the Royal Naval Hospital, Plymouth, the wife of R. Hall More, M.D., R.N., of a son.

Deaths.

QUIN.—On Nov. 24, at Queen Anne's Mansions, Westminster. F. H. Foster Quin, M.D., aged 78.

SMITH.—On Nov. 16, in South Australia, Arthur Wm. Smith, M.D., of Adelaide, aged 31, youngest son of Solomon Smith, M.R.C.S., of Halifax, Yorks.

WATTS.—On Nov. 10, at Thatcham, Berks, George H. Watts, M.R.C.S., aged 61.

AS LADY HOUSEKEEPER, also payment offered for board and residence in a nice home, by the daughter of a late physician, independent means, thirty-five, agreeable manner and appearance, cheerful and domesticated. Would be found a great acquisition in the house of a medical man.—Address, L. E. L., 36 Preston Street, Brighton.

IRISH POOR-LAW INTELLIGENCE.

CORRESPONDENCE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of the 22nd ult. a notable letter appears signed "Scarlet Runner." I agree with the writer as to the propriety and necessity of joint action among us in our lawful demands, and I rejoice that the Association furnishes a means of such action. We have ourselves to thank—or rather the sycophants among us—for most of the humiliations to which we are subject, and I consider the "permissive" superannuation law one of the greatest. If we were true to ourselves as a body the public could not impose much on us. "If the Romans had not been geese, Cæsar could not have been a wolf." I, for one, am ready to join "Scarlet Runner" in any such scheme as he suggests, but I would *not* agree with him as to making minimum salaries a condition of the acceptance of office. I believe in free trade in every commodity which is purchasable for money, therefore in medical services as in other things. I believe the time will come—and would it were come!—when some such arrangement as the following will prevail in respect to the Poor-law service, viz. :—The dispensary doctor and the medical officer of health to be one and the same person as now, to be paid a sufficient salary for his support, and to be excluded altogether from private practice—after the model of the medical member of the Local Government Board. Under the present *régime* private practice takes up so much of his time and thoughts as in some instances to amount to a fraud upon the poorer community for whom the system is ostensibly in existence, and who are entirely dependent on it for medical aid. Many years ago I broached this idea, but of course it attracted no notice in any quarter capable of or likely to improve on it, and I suppose equally, of course, it will attract none now.

Nevertheless, Sir, you will see at a glance *how* it would work. It would then be the *direct interest of the doctor* to keep his district *as free from disease as he possibly could*. The sanitary laws would be worked by him with heart and goodwill, which under the present *régime*, I apprehend, in most instances are not. At the present time the class of diseases called zymotic, and supposed to be preventible by sanitary precautions, are very rife in some parts of the country, which has helped to draw from me these observations.

The above scheme (you will say) would be a long step in advance of the present one, yet I am sure it must commend itself to the *common sense* of every one. In case "Scarlet Runner" should favour us with anything more, I beg of him to do so under his real name, and assure him of one thing, *i.e.*, he need not be ashamed of his style if he always wields his pen as he has done in the letter which has called forth these remarks.

I am, Sir, yours faithfully,

S. T. HASLETT, M.D., &c.

Donegal, November 13.

VACCINATION.

The following interesting letter has been addressed by Dr. A. O. Speedy, of Dublin, to the Board of Guardians of the North Dublin Union :—

28 North Frederick Street, Rutland Square,
18th November, 1879.

GENTLEMEN,—I consider it my duty to report the circumstance of a malignant case of small-pox having occurred in my district. The patient was a young man, who had recently come to Dublin from Dunboyne. He only took ill on last Friday, and died this morning. He had not been vaccinated. In my experience, there are a considerable number of persons, more especially those born in the country districts, who have never been vaccinated. The great risk which such individuals incur is enormous, particularly when small-pox is prevalent.

I wish to draw attention to a brief extract from an important letter, addressed to a leading medical journal by the Managers of the London Metropolitan Asylum District, dated 30th October, 1879, on the subject of small-pox and vaccination :—

"The epidemic which visited London in the autumn of 1876, and prevailed with more or less intensity up to the present year, caused the medical superintendents of the several hospitals under the control of the Board to collect statistical facts which illustrate the advantages of efficient vaccination and revaccination, establishing beyond doubt the mitigating influences in small-pox cases of successful primary vaccination, and the preventive powers of efficient revaccination. The total number of cases treated in the Board's hospitals up to the 1st October, 1879, were 15,171. The total number of deaths during the period under consideration was 2,677; of these, 1,008 were vaccinated, and 1,669 were unvaccinated cases. The percentage mortality upon the whole of the admissions was therefore 17·6, being at the rate of 8·8 per cent. of the vaccinated, and no less than 44·4 per cent. of the unvaccinated. It may be observed that among the 11,412 vaccinated patients admitted are included the majority of those who stated that they had been vaccinated, but upon whom *no traces* of vaccination were discernible. The nurses and attendants employed at the various hospitals from time to time during the epidemic, have enjoyed absolute immunity from infection; and the few, some half dozen amongst nearly *one thousand*, who contracted the disease whilst discharging their duties had, from some cause or other, escaped revaccination before entering the wards."

The above statistics are a striking proof of the protective influences of vaccination and revaccination, and is in accord with all previous experiences of its beneficial effects. The history of all epidemics teaches the same lesson.

In my opinion, if revaccination were generally availed of, the present epidemic would cease to exist.

Digitized by Google

It is lamentable to think of the number of lives sacrificed, owing to the neglect of vaccination.

That the Public Services of European countries are alive to the importance of revaccination cannot be too widely known, the rule being that, previously to entering the army, navy, and various other services, the candidate must undergo revaccination.

I am, gentlemen, faithfully yours,

ALBERT O. SPEEDY.

A. O'Neill, Esq., J.P., Chairman, Board of Guardians, North Dublin Union.

BOYLE UNION.

COLONEL KING HARMAN, M.P., AND THE MEDICAL OFFICERS OF HEALTH.

LETTER of the L. G. B. read, requesting the guardians to re-consider their decision reducing the salaries of the sanitary officers on their re-appointment under the title of medical officers of health.

Chairman (Col. King Harman, M.P.).—You are aware, gentlemen, that the Carrick Board, which adopted a similar procedure to what we have done, have had a sealed order sent to them fixing the salaries of the medical officers of health at £20 each, and taking the matter out of their hands altogether. I think it a very grave and serious matter. It is rather a serious affair to be fighting a body like the L. G. B. I thought under the circumstances that ten minutes' conversation is better than a great deal of letter writing. I telegraphed to the President, Mr. Robinson, and I went to Dublin yesterday by the early train. I explained to him what I conceived to be the position of affairs, and he explained to me what he conceived to be the position of affairs. He told me that a similar course to ours had been adopted in, I think, nine unions, and in each of these cases the L. G. B. had sent down a sealed order fixing the salaries. I argued the point with him pretty strongly, and I stated —and I believe I stated as I wished to do so—the opinion of the majority of this board at the time we moved the reduction of salaries, that the reason we did so was that the sanitary officers were not doing any work for the money. I think we all know through the country the sanitary officers *have not done any extra work for their extra pay as such*. I said, in mentioning that, I did not wish to cast any blame on them, but my opinion is *they cannot do the duty. It is a work that should never have been thrown on them.* I think it is an invidious task that a doctor who lives by the people, should have to report his own patients, and bring them into court. In one case he might lose a patient, and in another a man of a dark night might peg a stone at him. *All the authorities of the L.G.B. were then called out, and they all agreed in my opinion it was a duty that should not be placed on the doctors;* but at the same time, as it is placed on them by Act of Parliament, until that is altered, they cannot be freed from it. I said we did not decrease the salaries because of the Vaccination Act, but we considered it a very opportune time to decrease the salaries, as the doctors were not left in a worse pecuniary position than before. Mr. Robinson said, as our object was retrenchment, he would make two or three suggestions to me, and one of them was that we should discontinue the services of the consulting sanitary officer, which would be a saving of £30 a-year. I said the board was unanimous in continuing the services of Dr. H. O'Farrell, as he was one of the oldest and most respected and valued officers, and who had not his salary raised when the others were, and therefore we were not in favour of lopping him off. Mr. Robinson seemed rather cornered, and he said, "What can we do? We have sent sealed orders to other boards, and how can we exempt you?" A suggestion was then made, and I said I would test the opinion of this board on it. I said the sanitary officers are not doing any work, and that there is a new order imposing on them fresh work; and I say the fresh work won't be done, as the present work is not done, and if you add nothing to nothing nothing remains (laughter). That is my argument. However, the suggestion is—that we are to continue the old salaries for six months, and if in that interval we find there is no value given for the money, the L. G. B. will allow us to re-consider the matter. I think it is a fair compromise. You cannot expect a large body like them to defer to us.

Mr. Powell said the additional work of the medical officers of health was merely on paper.

Chairman—What we are fighting for is not so much the £30 saving, as the question of principle, and whether we have a right of opinion or not; and the L. G. B. by their compromise say we have a right to our own opinion after six months.

Resolved—That the several dispensary officers be re-appointed medical officers of health for the period of six months at their former salaries.

LOCKING UP PAUPERS.

LAST week the coroner held an inquest in the Waterford Workhouse on the body of a woman, named Bridget Walsh, who had died on the previous Thursday in the workhouse.

Margaret Bennet deposed to the coroner that on the night in question, about eight o'clock, she retired to bed. The door was locked at that hour.

Coroner—Do you mean to say that all the inmates were locked in for the night? Yes.

Were they shut out from all communication with the outer world! Yes.

Mr. E. Power—Do you mean to say that no person in the ward had a key? No, sir.

I was awakened, I think, about ten o'clock, by a woman who was in the next bed to deceased, who shouted to me that Bridget Walsh was dead. I got up and went over to her bed, and found that she was dead.

Coroner—What did you do when you found her dead? I couldn't do anything because we were all locked in.

Coroner—This is a nice revelation. A lot of women are shut up in a ward and one of them taken ill, and there is no communication between that portion of the building and any of the responsible officers.

You say she died on Thursday night between eight and nine o'clock? Yes, sir.

The death was not reported to the police until Saturday evening.

Mr. Ryan (master) explained that he was not at home, and that if old women in this ward were not locked up at night the place would be robbed.

The Coroner regarded this explanation as exceedingly absurd. and stated that even if such were the case there should be some communication, say a bell and wire.

The jury found a verdict of death from natural causes, and appended to it their expression of opinion that it was necessary in the interest of the safety of the inmates that a resident medical officer should be attached to it.

BALLINAGH DISPENSARY COMMITTEE. CAVAN UNION.

A SPECIAL meeting of the above Dispensary Committee was held on Saturday the 16th inst., to take into consideration the necessity of erecting a residence for the doctor, under the recent "Dispensary Loan Act." A large number of members were present.

The minutes of former meetings having been read, which

Digitized by Google

had reference to the cancelling of visiting tickets, Mr. McGioney remarked, that he was of opinion the doctors themselves had a great deal to do in the matter; he (Mr. McGioney) in his own district, had been in the habit of giving tickets to persons not exactly entitled to receive medical attendance gratis, and yet not able to pay a large fee, and in such cases he marked 5s., or 7s. 6d., on the ticket, before giving it. He would like to hear Dr. Lyndon's views on the matter.

Dr. Lyndon.—The marking of 5s. or 7s. 6d. on a ticket, is perfectly illegal, as recently pointed out by the Local Government Board in the Arva case, and even were it not illegal, I would prefer taking proceedings against the member who issued the ticket and recover my usual fee, rather than accept a fee laid down by a member of a Dispensary Committee.

The subject then dropped.

The Chairman having stated the business before the meeting, and the recent "Dispensary Loan Act" having been read,—

Mr. McGioney said.—I am surprised that a gentleman like Dr. Lyndon should make such an application, considering the present state of the country, and the already heavy taxation that is placed on the people. I cannot see how we can undertake such a responsibility.

Dr. Lyndon.—I am the last person in the room who would ask anything that is unfair, or that would materially increase taxation. Recent legislation empowers the Board of Guardians to raise money from the Board of Works, with special advantages, for the purpose of building the house, and I merely ask the Committee whether there is a necessity for it, and if so, to recommend the matter to the Board of Guardians.

The Chairman.—The doctor's statement is a very fair one.

Mr. McGioney.—Our doctors are paid fair salaries for performing their duties, and I don't see what compliment we are under to Dr. Lyndon to build a house for him.

Dr. Lyndon.—I don't ask it as a matter of "compliment," but as a matter of justice; neither, as I have stated before, do I ask you to build the house (as you have not the power), but simply recommend the Board of Guardians to do so. I am satisfied to pay a moderate rent, which will go some distance in clearing off the percentage paid for the loan, and besides, at the expiration of 35 years, the house will become the sole property of the Board of Guardians.

Mr. Meikle, Secretary.—I think it would be a grand speculation for the Board of Guardians.

Mr. H. Fegan.—I am of the same opinion, and I can see no reason why we should not try and do what we can in the matter.

Mr. Wm. Foster.—Although it may slightly increase the rates at first, it will materially lessen them after some time.

Mr. McGioney.—Well, I propose that the subject be not entertained, good or bad.

Mr. Patrick Brady.—Considering the present state of the country, I second that.

On an amendment to the contrary being about to be made, Mr. McGioney consented to withdraw his proposition, and finally the matter was postponed for three weeks, in order that the Chairman and Secretary might come to an arrangement with the landlord, relative to a suitable site and lease.

BALLYROAN DISPENSARY ELECTION.

A SPECIAL meeting of this committee was held to elect a medical officer for the district, the proceedings of the former meeting being nilled by the Local Government Board, owing to informality. There were two candidates, Dr. Blunden and Dr. Coyne. A division was called with the following result—for Dr. Blunden 7; for Dr. Coyne 5.

MONAGHAN BOARD OF GUARDIANS.

DR. Ross entered the board-room and handed a letter of resignation of the office of medical officer of Monaghan Workhouse, which he had held for the past seven and a half years.

The Chairman said he was very sorry to receive this communication, for he thought Mr. Ross was active, attentive, gifted, and energetic, and he believed above all things he was kind and considerate toward those who were placed under his care. He was quite taken by surprise, for no person knew anything, so far as he had heard, of Dr. Ross's intention to resign his post. Could anyone have given him offence? or was he about to leave Monaghan?

Mr. J. M. Ross had heard nothing at all about his intention to resign.

The Chairman—He seems to be a man who keeps his own counsel.

Mr. Murray—Apparently.

Dr. Ross's resignation was accepted with expressions of regret for the loss of his services.

MOUNTMELLICK UNION.

EXAMINATION OF LUNATICS.

MR. COBBE said there was a letter received from Mr. Turpin last board day relative to doctors' fees for the examination of lunatics. The Act of Parliament specifies that a doctor for examining a lunatic is to get a "reasonable fee." He (Mr. Cobbe) held that that reasonable fee meant his (the doctor's) usual fee, and therefore he would propose—"That this board is not satisfied with Mr. Turpin's definition of the Act relative to the doctors' fees for the examination of dangerous lunatics. This board considers that the reasonable fee to be paid the doctor is his usual fee of one guinea, and that unless he incurs expenses outside his so examining the patient his fee should be only his ordinary fee, and this board are determined to pay no more."

DR. RICE'S CLAIM.

The following letter was read:—

"To Board of Guardians of Mountmellick Union.
"Mountmellick, 14th November, 1879.

"GENTLEMEN,—I have received instructions from Dr. Rice to apply to you for payment of £16 4s., due to him for discharging the duties of medical officer at the Mountmellick workhouse and dispensary during Dr. Clarke's illness, for five weeks ending 16th August last. Your early attention will oblige.

"Your obedient servant,
"JOHN ALEXANDER FITZGERALD."

The Clerk—Dr. Rice was offered £14 2s., which he refused. Dr. Clarke told me this day that he offered to pay him the balance, but he would not take it from him. Dr. Rice said if he had known at first he was only to be allowed three gulneas a week he would not have accepted it; but I have proof here that he was well aware of the salary allowed, and that he did accept it.

The Chairman—I think he ought not to be offered the cheque again; if he wants it let him ask for it.

TANDRAGEE DISPENSARY.

A MEETING of the committee was held to appoint a medical officer in succession to Dr. Hamilton, who recently resigned. There were two candidates for the situation—Dr. Taylor and Dr. Wallace. For Dr. Wallace, 6; for Dr. Taylor, 10. The Chairman accordingly declared Dr. Taylor elected by a majority of four votes.

ANTICIPATED INCREASE OF PAUPERISM IN IRELAND.

THE annexed circular has been forwarded by the Local Government Board to all unions in Ireland :

"The Local Government Board for Ireland desire to inform the board of guardians that they have had under consideration the reports of their inspectors on the condition and prospects of the poor in Ireland, from which they learn that there will probably be an unusual amount of distress in parts of the country during the coming winter, and an increased number of applications for relief.

"Under these circumstances the Local Government Board have to impress upon the board of guardians the importance of being prepared for the possible contingencies of the season, and of making due provision beforehand for ample stores of bedding and clothing to meet any degree of pressure on the workhouse which is likely to occur ; they should also give directions to have the unoccupied wards in the workhouse thoroughly cleansed and whitewashed, and placed in every respect in good and habitable order.

"The Local Government Board would also recommend the board of guardians to take into consideration the number and extent of the relief districts in the union, and to ascertain whether the relief officers would be in a position to discharge the important duties efficiently, should the condition of the poorer classes render it necessary to afford relief out of the workhouse more freely than at present.

"It is of the utmost importance in the interests both of the ratepayers and of the poor, that the functions of the relieving officers should be properly performed, and that these officers should always be accessible to destitute persons residing in all parts of their district ; these objects cannot be attained if the districts are not of moderate size, and the Local Government Board hope that in the view of the possible increased pressure of distress the board of guardians will consider whether the existing relief districts in their union require revision.

"The Local Government Board feel assured that they may rely on the Board of Guardians to make all arrangements which may be necessary for the effectual administration of the existing laws for the relief of the poor in their union during the winter season."

The circular having been fully considered,

The Chairman proposed, and Mr. Griffith seconded :—

"That the board have taken into consideration the circular letter of the Local Government Board dated the 14th November, and they beg to state that while they are most anxious to make every effort to render the workhouse available as far as they possibly can to meet the probable destitution of the approaching winter and spring, they are still of opinion that the capacity of the workhouse and the resources of the union will be utterly inadequate to meet the amount of destitution which the present state of things seem to indicate, and they therefore call on the Government to initiate such reproductive works as while they give employment to the poor will be of permanent advantage to the district."

The resolution was unanimously adopted.

TUAM GUARDIANS.

THE clerk of the Mountmellick union forwarded the annexed copy of a resolution passed at the meeting of the guardians of that union with reference to the fixing by sealed order the salaries of the medical officers of health at a higher rate of remuneration than the board proposed to pay them—"That the board [of guardians of the Mountmellick union] having heard the order of the Local Government Board, dated 24th Oct., 1879, which virtually sets aside both the feelings and common sense of this board, do hereby request Mr. Dease, M.P., to bring the interference of the Local Government Board before Parliament in order that some change may be made in the Act of Parliament under which they are appointed, which will prevent them acting in an arbitrary manner in matters of mere taxation, of which the guardians here ought to be the judges, as at present the Local Government Board seem to have a power to spend the money of the rate-payers contrary to the wishes of the guardians they appoint." The board having heard the foregoing, declined to adopt it.

A GRATIFYING "SELL."—When it became known, last week, that Dr. Ross, Monaghan, had resigned his appointment as physician to the County Monaghan Fever Hospital, a number of gentlemen rushed to the house of the secretary, and paid him a guinea each, in order to qualify themselves, as they thought, to vote at the election of his successor. That officer took all the money he was offered, amounting to twenty-four guineas, and thanked the donors, who thought that all who paid before the Road Sessions were safe to vote. It now turns out, however, that according to Act of Parliament none but subscribers of a year's standing can do so, and the benevolence of the donors won't serve the purpose which they intended it should.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF OCTOBER, 1879.

OCTOBER 8th.—Parker, Thomas William ; Somerville, York Road, Kingston, co. Dublin ; Lic. R. Coll. Surg. Irel. 1879.

9th.—Hearn, George Beresford ; Dungarvan, co. Waterford ; Lic. Fac. Phys. Surg. Glas. 1879, Lic. Apoth. Hall Dub. 1879.

9th.—Browne, Samuel Cairns ; Castle Caulfield, Dungannon, co. Tyrone ; Lic. R. Coll. Surg. Irel. 1879.

11th.—Pooley, William ; Rochdale, Lancashire ; Lic. R. Coll. Surg. Irel. 1879.

16th.—Moffitt, Thomas Beattie ; Derrylin, co. Fermanagh ; Lic. R. Coll. Surg. Irel. 1879, Lic. 1879 and Lic. Mid. 1879 K. Q. Coll. Phys. Irel.

16th.—O'Connor, Charles Joseph ; Galbally, co. Tipperary ; Lic. R. Coll. Surg. Irel. 1878, Lic. 1879 and Lic. Mid. 1879 K. Q. Coll. Phys. Irel.

16th.—Simpson, John ; Cooke Terrace, Belfast ; M.D. Q. Univ. Irel. 1879.

21st.—Stevenson, Frederick Charles ; Rugeley, Staffordshire ; Lic. R. Coll. Surg. Irel. 1879.

21st.—Browne, Danby ; Clones, co. Monaghan ; Lic. R. Coll. Surg. Irel. 1879.

24th.—Lawless, George Robert ; 98 Bushfield Avenue, co. Dublin ; Lic. 1879. K. Q. Coll. Phys. Irel., Lic. 1879 and Lic. Mid. 1879 R. Coll. Surg. Irel.

24th.—Ring, William ; 28 Grattan Hill, Cork ; Lic. R. Coll. Phys. Edin. 1879, Lic. R. Coll. Surg. Edin. 1879.

27th.—Deane, Abraham Addison Hargrave ; 56 Upper Mount Street, Dublin ; Lic. 1879 and Lic. Mid. 1879 R. Coll. Surg. Irel., Lic. R. Coll. Phys. Edin. 1879.

28th.—Wheeler, Thomas Kennedy ; 3 Clarendon Place, Belfast ; M.D. Q. Univ. Irel. 1879.

MEMORANDUM.

The following names have been erased from the Register of the Branch Medical Council, Ireland, during the month of October, 1879, pursuant to the 14th section of the Medical Act, no reply having been received to several letters of application, viz. :—

Hall, John Henry Wynne ; Albert Terrace, Clapham, Surrey
O'Reilly, Laurence ; 11 Goldsmith Street, Dublin.
Potter, John ; Kilkenny.
Shaw, Alfred ; Carlow.
O'Sullivan, Jeremiah ; Boherbay, co. Cork.
O'Shaughnessy, James ; 12 George's St., Limerick.
O'Ryan, Anthony ; Carrick-on-Suir, co. Tipperary.
Phayre, Alexander ; 76 Harcourt Street, Dublin.
Phillips, Samuel ; Ballygawley, co. Tyrone.
Smyth, John ; Castle Place, Belfast.
Smyth, Fœde ; 26 Patrick Street, Cork.
McMullin, John, Joseph Ryan ; Sydney, New South Wales
McKeagh, Daniel ; Nenagh, co. Tipperary.

DIPHTHERIA.

By W. H. DAY, M.D.,

Physician to the Samaritan Hospital for Women and Children.

Symptoms.—Period of Incubation—Insidious Approach of the Disease before any complaint of Illness is made—Elevation of Temperature—Weakness of the Pulse an Early and Significant Feature of the Disease—Albumen in the Urine—Character of the Throat Affection and Peculiarities of the Exudation—Constitutional Depression and Implication of the Larynx and Voice—Diphtheritic Croup—Tendency to Delirium and Restlessness—Death by Suffocation or Asthenia.

Causes.—Influence of a Specific Cause—Debility and Exhaustion predispose to the Affection—Effects of Locality and Moisture in favouring its Occurrence.

Sequelæ.—Anæmia, Debility, and Paresis—Weak Action of the Heart, Secondary Endocarditis—Paralysis of the Muscles of Deglutition and Upper and Lower Extremities—Impaired Vision and Deafness—Bronchitis and Pneumonia—Albuminuria—Hæmorrhage from Nose and Bronchi.

Morbid Anatomy.—Bronchitis and Pneumonia—Fibrinous Coagula in the Heart—Congestion of Kidneys, Brain, and Spinal Chord.

Diagnosis of the Affection from Croup, Scarlet Fever, and Tonsillitis—Theory of Contagion.

Treatment.—Local and Constitutional—Necessity of Supporting the General Strength by Nourishment and Stimulants—Value of Iron and other Tonic Preparations—Applications to the Throat as in Scarlet Fever—Importance of Tracheotomy in Imminent Death from Suffocation—Dr. Buchanan's Statistics in Croup and Diphtheria.

Diphtheria (Diphtherite of Bretonneau) is a contagious nd epidemic disorder, characterised by a specific inflammation of the pharynx and air passages, attended with the exudation of fibrin or other lymph, and the enlargement of the cervical glands. Other mucous membranes or the skin may be sometimes involved. The vital powers are greatly prostrated. Death takes place from exhaustion or suffocation through diphtheritic deposit in the trachea and larynx. Diphtheria bears an affinity to the exanthemata in the fact that it chiefly attacks the young. The mortality is greatest between the age of five and ten years, but infants of a few days old have been attacked.

Evidence of the antiquity of the disease is to be found in the writings of Hippocrates, Celsus, Aretæus, Galen and Cœlius Aurelianus. In more modern times descriptions of it are given by Spanish, Italian, French, and English writers, and traces of its progress have been met with in America, Africa, and Hindostan. It prevailed in Holland in the sixteenth century. By some writers it is thought to be the same disease that was known a hundred years ago under the name of epidemic croup, and malignant sore throat. (*a*) It made its appearance at Tours, in France, in 1818.

This disease until the last few years has been confounded with erysipelas and scarlet fever during their epidemic prevalence. The credit belongs to Bretonneau of being the first writer to define its exact nature, and to show that the local appearances on the throat and fauces are the manifestations of a general and constitutional disorder.

Since the beginning of this century cases of diphtheria have been recorded from time to time by English physicians. In the years 1858 and 1859 the epidemic attained its maximum in this country, and in two years about 20,000 persons fell victims to it. (*b*)

Symptoms.—The incubation period is usually very short. "According to Oertels, the latest and best writer upon the disease, it may be stated positively to occupy from two to five days. His own experiments also show that in from twelve to twenty-four hours after artificial inoculation

(*a*) Dr. Fothergill's account of the sore throat attended with ulcers, 1748.

(*b*) "On Diphtheria," by Dr. Squire. "Reynold's System of Medicine," vol. i., page 11.

Digitized by Google

upon the surface of wounds we can detect a greyish-white discolouration, a dirty greyish layer, and the other signs of infection." (*a*) Dr. Morell Mackenzie has given an instance of a prolonged period of incubation, fifteen days elapsing from the exposure to contagion to the appearance of diphtheria. (*b*) The disease creeps on very insidiously, and may have advanced considerably before any complaint is made about the throat. The earliest symptoms are chilliness, weakness, and lassitude, with pain in the back and limbs, followed by febrile disturbance of varying duration. In some severe cases the fever is transient and soon passes off, but in mild cases it is of longer duration. Elevation of temperature generally marks the commencement of the disease, it may soon reach 103° or 104°, when delirium is often present; but in many cases the temperature appears to fall as the disease advances, the skin becoming cold, and the pulse slow. These symptoms often precede death. There is headache, thirst, and pallor of the face; the sleep is restless and uneasy, the mental faculties are clouded or excited; the pulse is almost always quick at the beginning of the complaint, and soon becomes weak and compressible. Cases are recorded of unusual slowness of the pulse, and Dr. Heslop mentions one in a child of five years of age, where it did not exceed forty beats a minute. (*c*) The tongue is covered with a thin creamy fur, or it is quite clean except at the posterior part. The appetite for food is small, and the prostration of strength so great, that the patient is too weak to exert himself to take food, and consequently many patients die, who reasonably might be expected to recover, if they could take a proper amount of nourishment. The urine is pale or contains urates or even phosphates, and at an early stage albumen is frequently found.

On looking into the throat some redness or swelling may be observed on the fauces, pharynx, and tonsils; the cervical glands are enlarged; there is pain in deglutition, and stiffness of the neck in separating the jaws. The eyes have a heavy languid look, and the conjunctival vessels are injected; the nostrils are inflamed, or obstructed from swelling of the Schneiderian membrane, or the presence of a tenacious secretion. Between the first and second day, from the commencement of the throat symptoms, the tonsils become more turgid, and a fibrinous exudation can be seen coating them, as well as on the back of the pharynx, which is now turgid, and assume a claret hue. Over a part of the inflamed surface a tough layer of grey-looking lymph is deposited, resembling wetted chamois leather or damp parchment, which continues to increase in thickness; in some instances it is very thin and superficial. This *false membrane* (which is pathognomonic of the disease) is not invariably of the same colour; in some cases it presents a dirty white or yellowish appearance; in others it is of a brownish or ash-coloured hue, and in exceptional cases it has a blackish gangrenous look, and is horribly offensive. (*d*) (*e*)

In some cases the exudation is first seen on the soft palate, or on one or both tonsils, but wherever it may be, it either extends from one part to another, or it simultaneously appears on several parts at the same time. Spots of exudation, which at first are separate and distinct, will coalesce and form a continuous layer in a few hours. The extent and colour of the exudation are generally in proportion to the severity of the disease. When there is a light and small distinct patch, the disease is mild, and runs a favourable course; but when the exudation is extensive or thick, or the patches unite or form a continuous layer, then the constitutional depression is great, and the patient is in imminent danger of his life. In some cases cough is a very early symptom. In June, 1869, a boy, aged six years, presented himself in the out-patient department of the Samaritan Hospital, whose illness began with a slight cough on the 5th. On the 8th, when he came under notice, he had a hoarse and frequent cough, and his voice was subdued and husky. On the lower part of the pharynx and right tonsil was the characteristic membrane, the child was very weak and pallid, the tongue coated, and the pulse 140, and feeble. He made a good recovery, the only sequela being enlargement of the tonsils.

When the exudation has fully formed, it mingles with the secretion from the mucous follicles, and the cervical and submaxillary glands become enlarged, and the whole neck swells. The child is now much distressed, as there is great pain in swallowing, and the poisonous secretion excoriates the mouth and nostrils. As portions of the deposit separate from the throat and are coughed up, there is great fœtor of the breath, and sometimes bleeding from the mouth and nose. This exudation is tough and fibrinous, and does not separate easily, except where it is undergoing decomposition. When it has separated it leaves a smooth bleeding surface, on which the exudation rapidly forms again. As the disease goes on the respiration becomes impeded by the obstruction to the entrance of air through the larynx, producing diphtheritic croup, (*a*) and the breathing is croupy and stridulous. The voice is muffled or reduced to a whisper, and the eyes are staring and suffused. The vessels of the neck are distended, and at each inspiration the depressions above and below the clavicles are sucked inwards and the epigastrium is retracted. With these alarming symptoms there are also pains in the head, which the child moves incessantly; the surface of the skin is cold and clammy, and there is extreme agitation and restlessness. The consciousness becomes more and more impaired, and the child dies suffocated and exhausted. Death ensues as in fatal cases of croup from asphyxia.

When the pharyngeal affection is acute and severe there is great pain and difficulty in swallowing food, but as the disease advances the sensibility becomes blunted, and there is no complaint of pain. The patient sinks low in the bed on his back, and is insensible to all that goes on around him, or he is delirious and muttering; the impulse of the heart against the walls of the chest grows weaker, and the pulse becomes feeble and imperceptible. In such cases death ensues from asthenia, or syncope. When laryngeal symptoms occur, the patient may die in the course of two days, but when they are absent death may not happen for two or three weeks. In cases that recover convalescence begins about the second week. "Of the seventy-four cases collected by the *British Medical Journal*, twenty-six died—fourteen from asthenia, eight from implication of the larynx, three from syncope, and one from subsequent bronchitis." (*b*)

(*a*) Article "Diphtheria," Ziemssen's Cyclopædia of Medicine, vol. i., page 594. Quoted by Murchison, Clin. Trans., 1878, page 248.

(*b*) "On Diphtheria," 1879; page 19.

(*c*) Greenhow on "Diphtheria," page 211.

(*d*) "The diphtheritic pseudo-membranes, or to speak more precisely, the diphtheritic sloughs, result from superficial gangrene of the mucous membrane, which again depends on compression of its nutrient vessels by an interstitial fibrinous exudation, or from swelling of the tissue elements, which are filled with a cloudy substance."—Niemeyer's "Practical Medicine," vol. ii., page 615.

(*e*) Inflammation is not essential to the disease, according to some authorities; but this is a question which pathology ought to decide. Diphtheria is distinguished by a peculiar morbid condition of the mucous membrane of the throat and tonsils. A sero-mucous effusion is poured out on the back of the throat, which becomes changed into a tenacious membrane, followed by the formation of another similar membranous formation till a tough plastic layer is produced. The false membrane can be raised from the surface which is ulcerated and bleeding. The pellicle of false membrane is chiefly made up of thickened epithelium, coagulable lymph, pus and blood corpuscles.

(*a*) Diphtheritic croup is more common in some epidemics than in others. The disease shows no uniform disposition to attack the larynx and trachea; many cases have terminated through sheer exhaustion, though there has been severe throat complication and sloughing; whilst other cases, and even some epidemics, have been marked by the extension of the disease into the larynx, and the symptoms of croup, with the throat and fauces comparatively free.

(*b*) "On Diphtheria," b Dr. Squire. *Op. cit.*, p. 139.

Digitized by Google

Diphtheria does not seize upon the stomach or intestines, or interior of the body, but on those parts of the mucous membrane continuous with the epidermis.

(To be continued.)

A FEW NOTES OF TWO CASES OF TETANUS SUCCESSFULLY TREATED.

Under the care of JAMES O'FLANAGAN,
Houghton-le-Spring, Durham.

TETANUS, whether general or partial, and especially when it is traumatic in course, is generally such a formidable disease to combat that the following notes of two cases, successfully treated, may be not without interest to the readers of the *Medical Press*. The first case, from being purely idiopathic, only little interest would attach thereto if it fell to be described by itself; but having occurred long anterior to the other case, and so having made as it were the lines of treatment for the latter, ungrateful or at least improper it would be to shunt it now entirely out of notice.

At one o'clock a.m., on Saturday, 23rd May, 1874, I was called upon by a former patient of mine, and requested by him to visit his daughter, who was then suffering from locked jaw. To my inquiry if it had arisen from a burn, wound, or other injury, the reply was "No; but from rheumatism or tic." I learned also that the tic had commenced some six months before, and had contined with some intermissions until the present time. I immediately dressed for the journey (some four miles) and prepared a twelve-ounce mixture containing the following ingredients:—Iodide and bromide of potassium, bicarbonate of potass, wine of colchicum, Fleming's tincture of aconite, chloric ether, water. I also carried with me a stopped bottle containing six ounces of chloroform. My horse being prepared for the journey during the above preparations, we set out, and on the road I continued my inquiries abour the case, and learned the following particulars:—The patient was 17 years old. Six months ago she complained of severe neuralgia, and in about ten days from that time her jaws closed, so that she could swallow only fluids, and those only with difficulty, and through the teeth. She was attended successively by some three or four medical men, who from the statements made to me of their practice in the case, appeared to believe that surgical manipulation (forcible opening of the jaws) was treatment more proper than the administration of any remedies internally. After some time the rigidity of the jaws relaxed so far as to allow her to swallow with less difficulty, but she was never able to open her mouth to the width of half an inch, and the neuralgia continued, as already described. About twelve days' time from the present (23rd May, 1874) the family had removed to a new dwelling-place, and on the journey (a distance of some twelve or fourteen miles) she "got cold," and her sufferings in consequence became aggravated. Having arrived at the patient's house in about an hour from the "call" (about two o'clock) I now found the case to be one of *trismus*. The jaws were certainly locked, and locked most immovably, the countenance was anxious and agonized, the complainings incessant, but there was no *opisthotonos* or other curving of the body from its normal posture. I immediately gave chloroform by inhalation, and continued it until the teeth could be forced open so far as to receive inside the mouth (only by sucking however) a dose of the medicine (*a*) above mentioned; and this being swallowed, I repeated the chloroform inhalation until complete anæsthesia occurred, when she slept for two hours at a "stretch." At five a.m. I repeated the chloroform, and having again got her to sleep, I returned home to attend to my ordinary visits. At twelve noon I visited patient again, and much to my satisfaction I learned that she had slept a good deal during my absence, but was now awake. The teeth were still firmly locked as before, but the pain was much less, as was evidenced by the complainings being less severe than at my first call in the morning. Repeated chloroform partially now, and to each dose of medicine I added twenty grains of hydrate of chloral. Having administered a dose, I left pointed instructions that the medicine was to be repeated *every half hour* till patient slept. With the second dose patient did fall asleep, and waking in some hours after the medicine was again repeated, when sleep again succeeding, she now "slept the clock round."

The morning of 24th I made my visit early, and was pleased at the report since last visit, and more pleased to find that the jaws could be opened by patient so far as to admit within them the blade of a palate knife or spoon. With a continuation of the medicine (every three or four hours now) I ordered, in addition, a strong infusion of senna, with Epsom salts, to be given so as to get the bowels soon and freely moved; and when this should occur nourishment to be freely given, such as milk and strong soups.

Monday, 25th.—Patient still improving. Has passed another good night. Bowels freely moved; motions dark and offensive. Jaws more open, and still relaxing. Able to take nourishment moderately.

26th.—Report similar to that of yesterday. The recovery now from day to day was progressive.

On June 15th I made my last visit, and as I was then about to take my summer holidays I left behind me directions for a supply of medicine (without chloral) if required. A single sixteen-ounce bottleful in tablespoonful doses from prescription already stated, was obtained, and taken with result as follows:—The stiffness of jaws gradually gave way, and about September patient could open her mouth to full extent. She has never been under my treatment since, and at last report (Nov. 8th, 1879) was quite well, but troubled with a mild return of tic from time to time.

CASE II.—On Monday evening, 29th Sept., 1879, M. F., school-girl, æt. 9, got her right foot entangled accidentally in the wheel of a waggon in motion, on the hinder part of which she was sitting at the time. Instantly and instinctively she essayed to withdraw it, and in this was so far successful, that a piece from the upper of a strong boot was torn clean away by the "pull," and along with the leather came the last joint of the great toe. As medical attendant of the family they sought me without delay, but I could not attend that night. At nine o'clock the following morning I made my call, and the particulars being explained to me by the mother (a person of superior intelligence), I decided to do nothing to the wound itself then, as it was carefully wrapped in lint, and the hæmorrhage at the time had been only slight—the dressings to be simply the already applied lint wetted with tepid water. As the patient had not slept, however, during the night, and was also feverish, and complaining of much pain in leg and thigh, I prescribed a mixture containing Fleming's tincture of aconite, liquor ammoniæ acetatis, and nitric and chloric ethers. This to be given every four hours. From commencing to take this mixture patient felt no more pain, and when I called, 1st and 2nd of October, the report on each day was that she had slept well the night before, and that her appetite was fair. After this I did not see her again till I made a casual call on October 11th.

On 9th October patient complained of slight pain, and stiffness in small of back, but this was made so little account of that at my visit on 11th no mention was made to me of it. Nor did my inquiries tend to bring out the fact, as she was playing then with the other children, and laughing "as usual." After my departure on the 11th, however, she complained of stiffness of jaws, and sore throat. This continued to grow worse on the day following (Sunday), but was set down by the parents

(*a*) Each dose contained 5 grs. iod. potass., 30 grs. bromide do. 15 grs. bicarb. potass., 20 minims vin. colchici, and 4 minims tr. aconite (Fleming's).

Digitized by Google

as from an ordinary "cold," and thus they did communicate with me.

On Monday evening, at 7.30, however, just as I was preparing for a journey of some four or five miles to assist at a post-mortem, at the request of the district coroner, the father came to me with the woeful intelligence that the little sufferer had locked jaw, and had been ill all day. A conveyance being ready to carry me to the inquest, I lost no time in making a *detour* to see the patient first, and I carried with me, as in the former case, some chloroform, and a bottle of medicine. Each dose of this medicine consisted of 2½ minims Fleming's tincture, 15 grs. bromide of potassium, and 7 grs. hydrate of chloral in a tablespoonful of water, with a little chloric ether to neutralise the disagreeable flavour of the chloral.

Having arrived at the house, I found the father's report to be only too true. There was well marked *opisthotonos*, the teeth were clenched, there was the peculiar querulousness of voice, and the *risus sardonicus* of lips, and worse than all the regularly recurring and terrible spasm—beginning at the extremity and continued up the trunk. I immediately gave chloroform by inhalation, and having got her partially under its influence, I succeeded in getting the jaws opened so wide, and the constriction of pharynx so much abated, that she swallowed without much difficulty a dose of the above-named mixture. I then continued the chloroform to complete insensibility, and when leaving left immediate directions, which were: "Give as soon as she awakes half an ounce of castor-oil, with half an ounce of oil of turpentine. And then give a dose of the mixture every half hour till she sleeps."

Tuesday, 14th.—Made my visit at eight a.m. Report since last night as follows: Has slept a good deal at intervals during the night, amounting in the aggregate to several hours. Given castor oil and turpentine, as advised, which produced copious black and offensive motions a little after midnight. Repeated the medicine after this, when she slept again till 2 a.m. Spasms less severe and less in frequency, although when they do occur she still bites her tongue. Given medicine again, during an intermission of these, and again slept for at least two hours. At six a.m. took breakfast of bread and milk, which being soft from the bread being steeped in warm milk, was swallowed without much difficulty. Urine rather scanty, and a desire to void it often. Pulse very variable, from 64 during an intermission to 110 after a spasm. Gave chloroform again, but not so fully as over-night, and ordered a repetition of medicine every hour as required. Support strength with milk, tea, and beef soup; and as thirst was urgent give ginger beer or lemonade *ad lib.*

Tuesday, 8 p.m.—A moderately favourable day. Teeth still clenched, and only able to open them after using chloroform. Has got medicine only once or twice since morning, either because it prevents the tongue, which is raw and wounded, from being so much bitten, or because the attempts to swallow it produce spasms and a sense of suffocation. Gave chloroform again, and while partially under it got her to swallow medicine. Directions at leaving—"Continue medicine as before."

Wednesday, 15th, 10 a.m.—Has passed a bad night; little or no sleep; spasms frequent and severe: tongue severely bitten and bleeding. Won't try to take medicine, but can suck through the teeth at times a little beef soup and drinks. Urine turbid and very scanty, and constant desire to void it. No action by bowels since yesterday about midnight. Put her again completely under chloroform, and changed the mixture thus (it being likely to be swallowed better, from being, at any-rate, more palatable):—

℞ Tr. aconiti (*Fleming's*) ʒi.
Chlorodyne, ʒss.
Potassii bromidi ʒij.
Liquor ammoniæ acet. ad ʒvj. M.

Two teaspoonsful to be taken every hour till it causes sleep. From the severity of the spasms, as evidenced among other things by the bitten tongue, the disease appeared to be now approaching its acme, and therefore if it could be kept from getting worse, and the strength kept up at the same time, we might hope to see it abate (according to certain authors) by about the twelfth day. With this in view, I made another visit at five p.m., and another again at midnight.

At five p.m. the report was that the day so far had been much more favourable than the preceding night. Had taken the last prescribed medicine with more regularity. Was able to suck through the teeth, and to swallow fluid nourishment and drinks, and had slept or at least slumbered a good deal during the day, especially after chloroform in the morning. Gave chloroform again now, and a dose of medicine before she was fully under the influence of the chloroform, as the jaws always relaxed considerably under the chloroform, thus making it much easier to swallow drinks and medicine. I left about two ounces of the former, and instructed the mother (mentioned before as a most intelligent person) to give it in my absence as she had observed me give it.

At midnight made my visit, and found her asleep. The mother had given the chloroform about 10 p.m., and then the medicine, both of which were now acting most beneficially. Was much troubled now with a cough, however, and an accumulation of mucus in mouth and throat, which threatened suffocation. Although the least movement of the body induced a spasm, I advised change of posture—turning her face under for a few moments—when suffocation was imminent, and to give internally some strong whisky punch. This stratagem succeeded so well that a quantity of mucus was expelled thereby, and so the more urgent danger was averted. Thursday and Friday things continued in about the same state as Wednesday. I made two visits each day, and the mother in my absence continued to give medicine, and also chloroform (a new supply of it obtained) three or four times in the twenty-four hours, as instructed. Cough troublesome. Urine very scanty—a few drops only at a time—very turbid, and a constant desire to void it. No action by bowels since Monday night. Plenty of "pop" to relieve thirst, taking nourishment freely. Ordered now a strong infusion of senna with Epsom salts dissolved therein, and got some of it swallowed by coaxing and bullying alternately.

Saturday, 18th.—Case certainly no worse; has passed a fair night; encouraged to persevere by the thought that by holding out till middle of next week will bring victory.

Made as usual two visits to-day. Patient very ill-tempered and hard to manage. Cries if mother is an instant out of sight. Complains much of tongue. Refuses medicine, but asks anxiously for "scent" (chloroform). Wound looks well, and is healing fast, the applications to it being (all the time) bathing from time to time in hot water; and hot poultices of linseed meal with a lotion added—composed of sulphate of copper, acetate of lead, acetic acid, tincture of opium, water.

Sunday, 19th.—Report exactly the same as yesterday—"certainly no worse." Treatment in all respects the same—"scent" included. No motion from bowels yet. Gave more senna and salts. Gave chloroform very fully at evening visit, as the taking of senna indisposed patient more than usual from taking medicine.

Monday, 20th, 11 a.m.—Has passed a very fair night. Bowels moved freely during the night two or three times; stool as black as tar. Urine more copious. Asks for "beef-tea" frequently, and for "scent" often. But though mixture has been repeated, takes it but seldom as possible, and then most unwillingly. A copious eruption of papillæ has appeared now on arms and legs. Augury good.

Monday, 7 p.m.—Little or no change since morning. Craves for "scent;" won't hear of medicine.

Tuesday, 21st.—No worse certainly. Night at least as good as the others. Still objects to medicine, while craving for "scent." Mother hits upon a new stratagem, which is to say that "scent" is exhausted, and no more can be had. Therefore obliged to fall back entirely upon medicine.

Wednesday, 22nd, 1 p.m.—Good news to-day. Can now open mouth an inch wide, or thereabouts, and spasms much less frequent and less severe. This morning about

Digitized by Google

four a.m. was nearly suffocated with mucus, but being placed immediately in the prone position, it became dislodged, and blood issued from mouth and nose, Continued to improve since that. Declared out of danger now. Medicine to be given less frequently—every three or four hours—but certainly at bed time.

Thursday, 23rd.—Still improving, but spasms bad at times from unwillingness to take medicine because declared by me "out of danger" yesterday. Go on with medicine for fear of a relapse.

Friday, 24th.—Still improving. Although jaws are much relaxed, the *opisthotonos* is not improved correspondingly, therefore the following liniment prescribed: Tr. Belladonnæ, linimentum camphoræ, glycerine ad ℥j. M. Ft. linimentum. To be rubbed over muscles of neck. The improvement was progressive now from day to day till 14th Nov., when I made my last visit. Saw patient again on 22nd Nov., when I called for final information for this report. The wound has been completely healed up some days. Patient is now convalescent—sitting up, but confined indoors. Not the least stiffness in neck or jaws, and can open mouth to full extent.

Remarks.—The very full doses of sedatives and—by inhalation and by mouth—antispasmodics, with the careful nursing of the mother, who for a period of eleven or twelve days was scarcely an hour absent from the bedside, saved the patient's life. Such a result will, it is hoped, encourage others to "do likewise" in a similar desperate case.

PYREXIAL EFFECTS OF CONSTIPATION.

By FREDERIC BARNES, M.R.C.P.

It has for a considerable time been noticed as a clinical phenomenon that there is a certain amount of relativity manifested in some cases between the height of temperature and the absence of alvine evacuations. This is more especially to be remarked in certain cases of a chronic or cachectic nature, which one notices now and then, in which there has been anteoedently, either a fairly normal or perhaps a slightly sub-febrile course of temperature, and then we are all at once surprised by an episodal increase of perhaps 4°, or even it may be as much as 5°, without any other accountable causal condition than inactivity of the bowels. I have most frequently noticed this incidental rise in the case of females, generally verging on the climacteric.

On administering a cathartic, the kind of which seems to be immaterial, the temperature immediately returns to its former level.

Wunderlich states that after this fall there is usually a considerable amount of reaction, and that there may even be a fresh rise surpassing the former elevation. This, however, so far as I have had experience, is on the contrary rather exceptional.

Conversely, it is also known that profuse catharsis exercises a depressing influence on the temperature, as may be instanced in critical diarrhœa, in cholera, &c. The condition of the bowels thus seems to exert some pyro-genetic influence on the system generally, either in a mediate or in a direct manner. But the mere retention of heat which should have been eliminated through the evacuation of the bowels, would hardly exercise so potential an effect on the temperature of the system at large. Wunderlich estimates the loss of heat from urinary and fæcal evacuation (taken together) as only from 1 to 2 per cent. But may not this hyper-normal heat-production be explained in some measure satisfactorily, by regarding the non-evacuation as an index (so to speak), of the condition of the whole alimentary tract, which is in a condition of lethargy. And inasmuch as this considerable surface is in a semi-quiescent state, a large portion of its normal blood current will be diverted into other channels, where the tissue changes will be more active, in this way substituting nutritive and metabolic activity for the relatively less heat-producing activity of osmosis. That this rise of temperature is not a concomitant of all cases of constipation, may be explained by the supposition, that in the majority of cases the heat-regulating factor comes into operation, and is able to set in action sufficiently active compensatory processes for the due elimination of the overplus of heat.

Westminster Hospital, S.W.

Clinical Records.

ST. PETER'S HOSPITAL.

Stone in the Bladder—Lithotomy—Recovery.

Under the care of Mr. TEEVAN.

Joseph B., æt. 13, was admitted into the hospital on July 9, 1879. He had visited the institution as an out-patient the same day, when he was sounded by Mr. Teevan, who found a stone.

History.—From notes taken by Mr. S. P. Phillips, the house-surgeon, it appeared that three years ago the boy began to suffer pain when making water. The only illnesses he had had were measles and whooping-cough. Both his parents were teetotallers. His mother was very healthy: his father died of paraplegia. The patient was born at Peckham, his father at Islington, and his mother at Beckenham.

Condition on admission.—The boy was pale and delicate-looking. Before and during the act of micturition he suffered much pain, and his water was sometimes tinged with blood. Occasionally he was attacked with retention of urine.

At 2.30 p.m. on July 16, the patient was put under the influence of chloroform by Mr. S. Knott. Mr. Teevan then passed a rectangular staff, which he committed to Mr. F. Heycock's charge, and extracted, by the lateral operation, a phosphatic stone, weighing seven drachms. As there was some hæmorrhage, a sponge plug was inserted into the wound.

At 8 p.m. the same evening the temperature was 101°.

July 17th.—Patient slept well; urine flows freely through the wound. Tongue clean; temperature 101°. The plug was removed, and a little bleeding occurred, which soon stopped.

18th.—Wound looks healthy. Some urine passes through the penis. Temp. 98°; pulse 120.

19th.—Urine flows freely through wound. Temp. 99°.

From this date the patient made a rapid and uninterrupted recovery. Urine commenced to flow through the penis on July 26th, and the patient left the hospital quite well and water-tight on August 1.

On September 8th the lad attended at the hospital to report himself. The wound was fully healed, and there was no incontinence of urine.

Stone in the Bladder—Lithotrity—Good result.

Charles H., a traveller, æt. 61, was admitted into the hospital on July 14, 1879. He had previously attended as an out-patient, when Mr. Teevan sounded him, and found a stone.

History.—From notes taken by Mr. Phillips, the house-surgeon, it appeared that fifteen months ago the patient commenced to be troubled very frequently to make water, and experienced pain along the urethra during the act. Never had any pain in the back, and never suffered from retention of urine or hæmaturia. Had always enjoyed good health, except in 1848, when he had typhoid fever, and in 1854, when he had erysipelas. Has been an abstemious man. The patient was born in London, his father in Norfolk and his mother in Suffolk.

Condition on admission.—Patient was in fair health, there was no albumen in his urine; his micturition was frequent and painful.

On July 16, at 3 p.m., Mr. Teevan introduced a litho-

Digitized by Google

trite, and found the stone to be ⅝ths of an inch by ½ an inch in its diameter. He then crushed it. The calculus was excessively hard, and composed of lithic acid.

17th.—There was no constitutional disturbance after the operation, and several fragments came away. The patient felt well and his tongue was clean.

22nd.—Mr. Teevan again performed lithotrity, crushing several pieces.

The next day and the following one some *débris* passed.

26th.—The patient being apparently quite well, Mr. Teevan sounded him, and finding no stone, allowed him to return home.

On August 1 he called at the hospital and said he felt quite well in all respects. He could hold his water for six hours, and suffered no pain. The urine was quite clear.

CLINICAL SOCIETY OF LONDON.

THE last meeting of this Society was held on Friday evening, November 28th.

MR. W. J. TYSON, M.B., F.R.C.S. (Folkestone), on

A CASE OF TRAUMATIC ANEURISM OF THE SCALP OF TWENTY-TWO MONTHS' DURATION.

W. M., æt. 56, hotel proprietor, in September, 1875, whilst out shooting, was struck by a stray shot on the back of the head, causing at the time considerable hæmorrhage, which was eventually stopped by cold water and the application of a handkerchief. The hæmorrhage did not recur, and a week elapsed before he saw a medical man; he then consulted my father, who detected nothing abnormal about the seat of injury. Five weeks later I saw him; he was then complaining of an indefinite kind of sensation about the parts, caused, as he thought, by the presence of a shot, but I failed to find anything like one. He was not seen again until Jan. 1877, sixteen months after the receipt of the injury; there was now a hard and firm hemispherical swelling, the size of an ordinary walnut, destitute of bruit and of pulsation; it was situated between the right mastoid process and the occipital protuberance; on puncturing the tumour a drop or two of blood escaped. Removal was recommended. In the following June he came to me again; the swelling had increased to the size of a small orange, still no pulsation could be felt or heard. On June 30, two days later, he was operated upon. A long horizontal incision was made across tumour, and whilst proceeding to dissect back the flaps, it was accidentally nicked, and furious hæmorrhage immediately came on; the lump was extracted as soon as possible, and a sponge placed in the wound; ultimately, after some difficulty, the bleeding was stopped, and firm pressure kept up. The next day, however, whilst removing the sponge, the hæmorrhage came on again; the vessel was secured by passing a tenaculum carrying a silken suture under it. The wound was a large one, over 4 inches in length and 1 in depth. For two days after the operation the patient was unable to retain much nourishment on account of the sickness which supervened. On July 2nd, he had a mild attack of delirium tremens; this lasted for three days. Hence he made a steady, but progressive recovery. The wound was washed out every morning with carbolic acid lotion, and afterwards carbolic oil dressing applied; the latter was continued until the wound had healed. On July 24th he went out for the first time, and on August 18th, seven weeks after the operation, the wound had completely healed. For two or three months he complained of numbness about the cicatrix, but this, after a while, disappeared.

Remarks.—I think that there can be little doubt as to the nature of the case, viz., a small and partial division of an artery; probably, from the situation, a branch joining the occipital with the posterior auricular. The skin wound had rapidly closed, leaving the vessel still open. The tumour was slowly increased in size by the gradual deposition of fibrin. The length of time which the aneurism had existed, considering it to be false, is very uncommon, but this is accounted for by the unyielding condition of the surrounding scalp. The skin over swelling was not thinned, and so it would be difficult to say how much longer the aneurism would have remained before bursting. The diagnosis plainly indicated by the history was obscured by the absence of pulsation or of a bruit, but I was painfully made aware of the nature of the case during the operation, for until the old clot was removed, the bleeding vessel could not be reached, and whilst doing so other vessels in the scalp were divided. I think the treatment adopted was the only one that could be recommended. The history of the case is instructive, for had the patient, in the first instance, consulted a doctor, and had he properly secured the vessel by dividing it, all further trouble might have been avoided, whereas, as it was, he certainly ran some risk of his life.

MR. HOWARD MARSH referred to an instance where an aneurism was mistaken for a sebaceous tumour, and its removal proceeded with. During the operation, an artery was accidentally wounded, and considerable hæmorrhage occurred. As in Mr. Tyson's case, the sac was opened, and subsequent cure by contraction followed. At St. Bartholomew's Hospital, Mr. Savory, having to operate for aneurism of the dorsal artery of the foot, opened the sac, and turned out the contents; the case did well.

MR. TYSON observed that in his case the aneurism was originally thought to be a sebaceous tumour.

MR. J. CROFT on

EXCISION OF BOTH HIP-JOINTS FOR SYMMETRICAL DISEASE (?) —FEMORAL NECROSIS—ANTISEPTIC OPERATIONS—SUCCESSFUL RESULT.

Ada G., æt. 4, was admitted under Mr. Croft's care in St. Thomas's Hospital on January 3rd, 1879, for hip-joint disease on both sides. Two years previously she had fallen downstairs. She had limped during the last eleven months, and complained of pain in both hips and knees. She had been under treatment at St. Thomas's Hospital as an out-patient for three months, and afterwards at the Children's Hospital, in Waterloo Bridge Road. She had suffered more or less from starting pains at night for eight months, and as much on one leg as the other. On admission she was miserably thin, and in bad health, and she was suffering from ulcerations of the cornea (strumous ophthalmia), as well as from the hip disease. There was well-marked muscular rigidity at each joint; attempts at movements caused pain. The thighs were somewhat flexed on the pelvis, and the legs on the thighs. The feet were rather everted. Spurious lardosis existed. There was no extensive swelling, and there was not any shortening She was allowed a good diet, with wine, and she was carefully nursed. The keratitis was treated and cured. The limbs were straightened and a modified double Thomas's splint adapted. Extension was maintained either by weights or elastic bands. During the month following her health steadily improved, though she suffered somewhat at night, and cried occasionally from starting pains. On the 26th February, or between seven and eight months after her admission, a collection—a fluid—was discovered between the great trochanter, and the ant. sup. spine of the ilium. About a fortnight later, or two months and a half after her admission, an attempt was made to evacuate the collection, or abscess, by the aspirator. A small quantity of thick puriform fluid was drawn off. Six months after her admission and seventeen months after she was first observed to limp decidedly, she was still suffering from muscular rigidity and occasional spasmodic pains in both joints. The fluid had re-collected on the left side. I therefore determined to excise the joints, and to operate on the left side first. On the 17th May the left joint was excised antiseptically, and as it has been termed, subperiosteally. The antiseptic treatment was well carried out by the house-surgeon, Mr. Castle, and the dressers, Messrs. Hokar and Panisty. Three weeks after the first operation the right hip-joint was excised (on June 7th) in the same way. The wound on the left side healed in about five weeks' time, and the right side rapidly followed the example of the left. With regard to the parts removed at the operations. On each side the femur was sawn across at the level of the base of the great trochanter. The surface of the acetabulum was freshened by means of the gouge. The remaining cartilage and the granulations were cut away with the same instrument. The synovial membrane and its granulations were dissected out, and the lining membrane of the abscess on the left side was removed. The surfaces remaining after these procedures were carefully washed with carbolic solution and a solution of chloride of zinc (40 grs. to ʒj.) was applied to them. A double modified Thomas's splint was employed in the after-treatment, and extension

Digitized by Google

kept up by india-rubber bands. Passive movements were commenced after the third week. The parts excised are placed before you. The parts from each side may be divided into four :—1. The epiphysis or capitellum ; 2. The main mass, consisting of the neck and top of the femur ; 3. Pieces of synovial membrane and bone cut out from the acetabulum ; and 4. Small pieces of detached dead bone. The epiphysis was found separated at the epiphysial line from the neck of the bone. On the left side its upper surface was for the most part bare, and small pieces of dead bone were adhering to it, and its under surface was irregular where it had separated from the epiphysial cartilage. The upper end of the neck of the bone was bare, small crumbs of dead bone were lying upon it, and adhered to it. Some of these pieces have become detached unavoidably during manipulations. No trace of epiphysal cartilage remained. The bare condition of the neck is owing to the fact that the operation was done subperiosteally. It should be noticed that none of the trochanteric epiphysis remains on the specimens. That process was preserved to the lining and left attached to the gluteal muscles. The parts from the right side exhibit very similar changes, which are here more demonstrable. The separation between the epiphysis and the neck is easily seen, though they are yet loosely connected. Two small sequestra may be seen deeply embedded on the neck of the bone, and a piece of dead cartilage is seen hanging by a thread of tissue to the epiphysis. The synovial membrane was swollen and the peri-synovial tissues infiltrated ; but their condition did not appear to be that of synovitis hyperplastica tuberculosa. The state of the parts justifies me in the opinion that there is symmetrical separation of the epiphysis on each side, and necrosis. My objects in showing this case are as follows :—1. To illustrate the value of operating early in hip-joint disease, before the third stage has advanced. 2. The value of operating antiseptically. 3. The value of removing the parts freely. 4. The value of leaving the great trochanter attached to the muscles which are fixed to it. And 5. The case is rare and interesting from its being one of double disease, and from the disease being symmetrical (?)

1st. *With regard to Early Operation.*—As the disease had been in progress for eleven months or more, it cannot be said that in point of time the operation was performed very early. It was not a case of *acute* necrosis of the epiphysis. That disease is attended by very urgent symptoms, and should be treated by very early operation. The case belongs to the chronic form of arthritis. I consider that the inflammatory changes began in the bone, and that the osteitis terminated in necrosis and caries. This osteitis necrotica led to inflammation of the joint tissues. The osteitis and arthritis combined to disorganise the joint. Had the case been allowed to take its course uninterrupted by operation, the surgeon following the routine treatment recommended for the second and third stages of hip disease—viz., rest, splints, opening abscesses as they arise, and so on—the child must have continued to be the victim of disease and suffering for many months, and probably for several years. The joints must have become stiff and immovable. This would have been a favourable course under the circumstances. She might have succumbed to tuberculosis of lungs or membranes of brain, or to amyloid changes in the abdominal viscera. I repeat that this case demonstrates the immense advantages which may be obtained by operating in good time.

2nd. *Antiseptic Operation.*—Without antiseptic precautions the operation of excision of this joint is followed by some febrile disturbance and numerous painful dressings. In this case we were successful in maintaining the antiseptic system. A reference to the temp. chart shows that absolutely no febrile movement ensued. I believe the child was in the matter of temperament an uncommonly favourable subject. She began laughing and playing soon after the immediate effects of the operation had subsided. Where there is reason to fear that the disease for which the operation is about to be undertaken is of a tubercular character, it is of consequence to prevent the induction of high temperature, that is, to avoid sharp febrile attacks. High temperatures appear to be favourable to the rapid propagation of tubercular changes.

3rd.—*The value of Removing the Diseased Parts freely.*—I attribute the good results in this case partly to having made the section of the femur on each side through undiseased bone, and to having dissected out or destroyed by chloride of zinc the remains of the diseased synovial membrane. A common cause of failure after excision of articular ends of bones is that of not cutting away all morbid bone or synovial membrane—in other words, of not having made the section through uncontaminated bone.

4th.—The gluteal muscles were not severed from their connection with the great trochanter. The attachment of the gluteus maximus to the great trochanter was split longitudinally, and the process of bone was also bisected, but the trochanter and its muscles were not separated. The trochanter has renewed its attachment to the shaft of the femur. To this I attribute the fact that this child has such remarkably good movements at the joint. She can abduct the leg, invert the foot, and flex the thigh on the pelvis to a great extent. There is no fear of bony ankylosis in her case.

5th.—*With regard to propriety of Excision in Hip Disease.*—Some surgeons still see many objections to excision at this joint, looking upon the operation as almost always fatal and hopeless. I do not agree with those who condemn the operation. I have now performed excision of this joint forty-five times. An analysis of my cases encourages me to continue the practice, and to practise the operation *early*. I would on this occasion direct attention to one result of an analysis of these cases. It is one which bears on the case before us this evening, and it is this : *Twenty-one* of the cases were instances of *necrosis* either of the top of the femur or of the acetabulum. I hold that if a surgeon knows that there is a piece of dead bone shut up in a joint he should perform an operation for the removal of that piece of dead bone. If a surgeon knows that a loose cartilage is irritating a joint he takes steps to remove that body in the safest manner possible. It appears to me that there are more cogent reasons for removing dead bone from a joint. I would condemn in the strongest terms the practice of leaving these cases of hip-joint disease unexplored and unrelieved.

6th.—Are there any signs or symptoms which may be taken to indicate certainly the presence of dead bone in hip-joint disease? Excluding acute inflammation of the joint, which presents very positive symptoms and signs, and limiting my remarks to chronic cases, I would say that those cases in which the symptoms are traced to an injury, and in which the signs and symptoms progress slowly, and without hyperplastic swellings, that those cases are probably instances of necrosis. A case in which the disease has advanced slowly in that way, and in which a collection of fluid (or abscess) has slowly formed is most probably one of necrosis.

7th.—I venture to submit the following formulæ as guides to operating :—1. When there is fluid in the joint antiseptic incision should be made as if the surgeon intended to excise, and he should only desist on finding the articular structures in a condition from which they could rapidly recover, and yield a movable joint. 2. When pus is known to be present, even if the surgeon is uncertain with regard to the state of the bone, he should excise. 3. If the surgeon is certain that necrosis has occurred he should certainly excise.

Mr. BRYANT said the whole question of the excision of joints was opened up by this paper, and several very important points illuatrated in it. The case, he considered, one of simple ostitis, not acute, and of a nature similar to nine-tenths of the infantile cases met with. The mischief was not synovial, a class of injury met with in older subjects as a rule. In fact, the case was a good typical sub-acute one. That the operation performed was a proper one, under the circumstances, no one could doubt. The disease has assumed a marked character ; and he thought that the *stage* of the disease, and not *time* merely should indicate the need of operative interference. He could not understand how Mr. Croft could describe his operation as a sub-periosteal one, for necrosed bone must be devoid of any membranous covering. In the case under notice, Mr. Croft did wisely in preserving the trochanter, and as much periosteum as possible. It is the imperative duty of the surgeon to save as useful and movable a joint as possible, but this carefulness might be carried to an extreme even. He had never, he said, satisfactorily succeeded in sub-periosteal operations for excision, and regarded the term as a mere ornamental expression to which no actual meaning could be attached. The operation could only be performed on a healthy subject, and therefore it must be an improper one. He strongly dissented from Mr. Croft's opinion that it is right to cut down into a joint, except on the strongest clinical evidence of disease, and the existence of pus. He felt he ought not to enter on the large question of antiseptic surgery, but he could not assent to all urged on its behalf. He thought excision should be done where necrosis was quite certain, but as long as the head of the femur is in the acetabulum, it is not possible to tell with certainty if dead bone

Digitized by Google

exists. But with indubitable proof of this, it is right to cut into the joint, and follow with resection. He would like to know more concerning the *early* incision mentioned in the paper. He doubted its propriety, and furthered questioned the accuracy of arranging hip-disease into *stages*. He had been disappointed with the results of resection in his own practice. There were but a few really excellent endings, the majority of limbs resected being only poor substitutes for a perfect one. In a very large number of cases, he admitted, no good result ensued, in consequence of delayed treatment, and this might be urged in defence of *early* operation. Alluding to antiseptic surgery, he feared that its introduction has induced the undertaking of operations not sanctioned by every experience; joints for instance being too freely opened, because of the confidence felt in the protective spray and dressings. In many instances those had been undoubtedly interfered with, which might have been pemanently cured by time and rest. As a surgeon of the pre-antiseptic period, he did not like to witness the readiness with which action was taken under the new system. He wished to hear more from Mr. Croft in reference to *early* interference.

Mr. HULKE congratulated Mr. Croft on the brilliant result he had attained. The history of the case proved that unfavourable conditions had existed, the child not having had the advantage, for one thing, of perfect rest. Operation, he said, should be resorted to as soon as possible when it is evident that necrosis is established in the joint. The determination of this time is, however, a very difficult matter, and he felt convinced that unless there be a conviction that the fluid collected is really pus, no interference ought to take place. Even with pus collected free incisions have often been sufficient to ensure a good recovery, so that pus does not of itself indicate the necessity for excision. He agreed with Mr. Bryant that, considering the operation, but a small mortality attended it; but much disappointment must be felt at the dwarfed nature of the limb that is the usual result of it. He endorsed the remarks made by Mr. Bryant concerning subperiosteal excisions, and had listened with much interest to Prof. Sayre's defence of the method some time since, when that surgeon was in England. But he did not feel satisfied that the periosteum was thereby preserved to an extent commensurate with the expectations to be formed from descriptions of the operation. All cases of this disease, even acute ones, would, he considered, eventually recover if submitted sufficiently early to treatment. In extreme cases he advocated free incision, but had never seen anything but harm follow the employment of the aspirator in hip-joint disease.

Mr. PARKER did not think the case could be rightly described as an *early* one. He noticed that on the charts exhibited, the temperature was recorded once as 100°, and varied for some time from 99°·4 to 100°. He was of opinion that a better classification of hip diseases was desirable in the interest of young surgeons, to guide them in the treatment to be adopted, especially since the disease runs very varying courses. Under the most careful treatment he had seen children progress from bad to worse, and in many had observed that the disease attacked also the side opposite to that first implicated. In five out of eight cases in which he had operated, he had removed sequestra of dead bone, and he therefore concluded it is very necessary to be assured of its existence at an early period. He felt uncertain as to the best mode in incision. In his own practice he adopted what he termed the antero-lateral incision. In making it he cut *in the direction of*, and not *across*, the muscular fibres, thus ensuring the best results. Then with a keyhole saw introduced from above, down, and in, he was enabled to separate the head of the femur without disturbing the trochanter, or injuring the periosteum or muscles. In reply to a question from Mr. Hulke, Mr. Parker said that in the five cases he referred to the dead bone was in the form of loose sequestra, and further confirmed his statement by producing the fragments for the inspection of those present.

Mr. BRYANT remarked on the unusually frequent occurrence of necrosed bone in Mr. Parker's practice. In his own experience of about fifty cases he had not so many. He hoped Mr. Parker would bring forward a record of his cases.

Mr. JONATHAN HUTCHINSON said that in his experience the separation of the epiphysis had been a rare event; he had seen it in only four or five instances. He had not noticed much perceptible necrosis in many cases. He agreed that disappointment usually resulted from the operation for excision. He had witnessed many cases in which the most dexterous surgeons had operated, but had never been enthusiastic in favour of the proceeding. Many successful recoveries at the time had succumbed at longer or shorter intervals after, and many had entirely failed of any good at all. These had mostly been cases of late operative interference. He thought they might help to sustain Mr. Croft's dictum that early adoption of radical measures of cure is essential in these cases. The use of plaster-of-Paris dressings to ensure perfect rest, might, he thought, be desirable; but he had seen the most marked benefit occur through the influence of change to seaside places, and, further, placed much reliance on counter-irritation over the seat of the affection in the early condition, which would, nevertheless, not justify the making of an incision into the joint. He recommended the covering of the whole joint in such treatment with tincture of capsicum, over which an oiled silk protective should be laid, and the whole permitted to remain for half-an-hour. He concluded by adding his congratulations on the successful result of Mr. Croft's operation.

Mr. MARSH had seen, he said, many excisions at the Children's and St. Bartholomew's Hospitals. The results were not encouraging. Out of 100 or 120 cases he could only point to six or seven entirely good results. This, he admitted, might be due to late operation and non-antiseptic treatment. His experience was so unsatisfactory that he would only with reluctance resort to the operation. At St. Bartholomew's it was only attempted three or four times a year. He objected that it is not possible to draw any conclusion from a single case as to the wisdom of the proceeding, but willingly admitted that the one brought forward by Mr. Croft was remarkable for the success attending it. He wished that gentleman would show and detail the histories of as many as possible of his forty-five cases. He agreed that necrosis is comparatively rare in hip disease, the condition of the bone noted being generally caries; of this carious material part must remain after operation, as its entire removal would involve the taking away of some three or four inches of the femur. It is certainly true that neglect alone gave a formidable aspect to the disease. In all cases, if resorted to early enough, sea-air and counter-irritation might be expected to work a cure. He knew cases, even, in which recovery had followed the existence of sinuses, the children being now able to walk about freely. He suggested that the child shown by Mr. Croft should be kept in sight, and brought before the Society hereafter. It might then be found that its power of locomotion has suffered. He thought that good *did* follow the use of the aspirator, having seen it employed with advantage. The objection that blocking of the tube frequently occurred might be got over by employing one of sufficient calibre.

Mr. CROFT explained that by *early* operation he meant interference at a stage later than that in which no perceptible effusion into the joint has taken place. This condition he should term the *incipient* stage. If treatment by rest be then adopted a favourable termination is certain. In the case he had recorded, however, the disease had progressed for seventeen months. The division of the disease into stages adopted by Sayre and other surgeons, is useful for descriptive purposes, as in syphilis it is found convenient to speak of various conditions. The first stage in hip disease terminates with effusion into joint; the second extends from the effusion to the opening of the abscess; the third from this point to the end. Thus a child in the second stage is, in a pathological sense, only in an early stage of the disease. He had confidence in the wisdom of incision into the joint, and especially since the splendid results of antiseptic treatment justified such a course. He urged that when the signs observed give evidence of extensive degeneration it is incumbent on the surgeon to make incisions at times, not alone to verify his assumptions, but to afford ease to his patient; and especially so, since the absolute certainty of healing that attends operations performed with minute antiseptic precautions. The term *subperiosteal* he had employed for want of a better to express his meaning. He had used it as explanatory of his method of procedure. The neck of the femur, he continued, can be turned out without the removal of any periosteum, since this is absent from the head of the bone; and hence he could not be said to speak of it in connection with that process. By *the antiseptic method* he meant Listerism pure and simple, and admitted no other system. Unsatisfactory results were all attributable to late operative interference. As to dead bone, he could not say there were any definite signs to indicate its presence, and had referred to it, therefore, in guarded language. He had not

Digitized by Google

employed the aspirator to draw off fluid from the capsule of the joint when only serum existed. He thought favourable results might ensue from tapping. That it was unwise to generalise from a single case, he admitted, but had adduced a *number* of cases to sustain the conclusions he had formed. He believed the child exhibited would gradually acquire a new joint, on which it will be able to balance and walk.

On the suggestion of Mr. Hulke and the President, Mr. Croft undertook to bring a record of all his cases before the Society; and Mr. Parker also promised to read reports of the cases to which he had referred in discussion at a future date.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 3, 1879.

POISON-VENDING.

IT is a misfortune that many very excellent substances employed by the physician in his ministrations, and potent to effect good when properly used, are by their nature calculated, in unskilled hands, to produce the direst consequences; occasionally amounting even to destruction of life. Though it is scarcely more than ten years since Dr. Richardson introduced chloral into this country, yet it is possible to count by hundreds the lives that have been sacrificed through the improper, or ignorant administration of the drug. Ignorant, we say, advisedly, for in almost every case of death by overdoses of chloral, the hypnotic has been obtained directly through the agency of an incompetent adviser, usually a chemist. If for this reason alone, we should be justified in demanding a speedy and sweeping reform in the system by which the "chemist and druggist" is empowered, to a great extent, to deal wholesale destruction in the vicinity of his shop. But we have constantly accumulating proof that the entire list of poisonous drugs must be carefully considered in its relation to the mortality of any given district, and more particularly, the larger towns and villages. In the face of the constant evidence that is being adduced in our police courts, and before our coroners, evidence that plainly indicates the immense evil of indiscriminate sales of poisons, we are compelled to raise a protest against the continuance of a system that permits such facilities as are now enjoyed by the incautious and the rash. We are by no means alone in the opinion we entertain, and assured of the support of an influential body, we do not hesitate to insist that the right to sell poisons irresponsibly, be withdrawn from counter-prescribers, and every other unqualified dispenser or vendor of medicines and drugs. The evil that is wrought by chemists in the present, is not calculable from the evident results, large though they are. Many more cases of injury, severe, and even fatal, than are publicly proclaimed, do occur; and it is in the direction of a prevention of these, as much as the more evident instances, that steps must be taken.

We have neither wish nor intention of impugning the capacity, or the integrity, of the chemists and druggists as a body. Only the greatest respect can be entertained for them; they are useful and essential assistants to the medical profession; and the corporation to which they are subject will be the first, we doubt not, to recognise the importance and the justice of the measure we are advocating. But from his position as a salesman, the chemist can exert only so much control over the use of poisonous materials as he is empowered by the Sale of Poisons Act. And the inefficient manner in which this Act is framed leaves much to be desired in the way of further improvement. Its provisions, as they stand, even if rigorously and invariably enforced, and we are sure they are not, are altogether inadequate to prevent the determined suicide from fulfilling his intention. So long as the purchase of poisons is possible, so long will the legitimate use of them be subverted to improper purposes.

One very valuable suggestion has been made in reference to the body which should regulate this particular traffic. It is to the effect that the power be vested in one of the three great corporations whose duty it naturally seems to be, viz., either the Colleges of Physicians, the Colleges of Surgeons, or the General Medical Council, the latter as being the responsible registering body for all practitioners. Held, as at present, by the ones directly interested in the *sale* of the articles, it is impossible for them to eliminate from their administration every irregularity attendant on the carrying out of specific rules for safety. Entirely unintentional, we gladly avow, these irregularities are; but from the nature of the connection existing between licensers and licensees, and the complicated questions of relationship and mutual obligation these involve, it is only to be anticipated that they will arise. That they have arisen, and been followed with most disastrous results in the past, needs no enforcing now.

In rare cases it undoubtedly happens that the claims of society, and of humanity, are subordinated to the sordid desire of gain entertained by the vendor. Though, however, the consideration of these is an important factor that will affect the whole question, we do not desire to

Digitized by Google

deal with it in this place. Apart from them, the most honourable and well-intentioned chemist may be morally guilty, any moment of his service, of the destruction of a life. Undesignedly he supplies an applicant with what may appear to him no more than a usual dose of a poisonous drug; and the next that he hears of his customer is a summons to give evidence touching his concern with his death. The occurrence is no rare one, and is a perfectly natural consequence of the present law. A patient has been given on one or two occasions, a sleeping draught by his regular medical attendant. He has procured it at the nearest chemist. He knows it by its name, chloral, and derives comfort from its use. By-and-by he returns to it without advice, and has no difficulty in obtaining his needs from the chemist at hand, who is at once satisfied by the production of the original prescription, even if he raises any objection on the first application. The customer continues his dosing, and, possibly, in a state eminently unfitted to take the drug, so that eventually he sinks under its effects, to the verdict of sudden death; generally attributed by an enlightened twelve to "natural causes." We repeat that the chemist shares no direct blame under such conditions; but if the sale of the drug were not thus loosely conducted; if, that is, it were obtainable only when specifically ordered, and sold on the authority of a practitioner's signature purposely given for that, and only that purchase, then we should hear less frequently the tale of death by inadvertence to which we have become so familiarised by repetition.

The licensing of the vendor is a matter of greater difficulty. How the system in use is to be modified to secure the safety we claim in the public behalf, it is not easy to see at once. It is not possible to employ as yet that "intellectual test" for which Professor Rolleston eloquently appeals; there can be resorted to, only the rough and ready practical gauge of an inefficient examination; and so long as this remains what it is, there is but little to be hoped for from it.

The General Medical Council has, however, a great power in the matter. It can "recommend" that no unqualified man shall have the power of supplying poisonous drugs to an applicant; and it can enforce by its authority the necessity of every individual dose of a poisonous material being directly prescribed by one of its own registered constituency. It is unreasonable that what is essentially a medicine should be ready to the inexperienced hand to deal with as may seem fitting to it; the restrictions sought to be imposed on the freedom of acquirement of dangerous articles are not destructive of the "liberty of the subject" so dear to sensation-mongers, for under the most irritating *espionage* there must always remain paths of destruction open to the one whose first intent is death.

The loose character of the legislation on the drug question is a blot on our internal government. We feel the time has come to alter it in the most radical fashion, and if proof were wanting yet, we need only point to the lists of drugs legally deemed poisonous, and to the other list on which no restrictions as to sale are placed, to establish our assumptions. Reform is necessary here, and should be immediate.

POOR-LAW MEDICAL SUPERANNUATION.—I.

THE letter from Mr. Dolan, F.R.C.S., in our issue of Nov. 26th, cannot be passed over without comment by us, as we some years back originated a similar scheme for the profession in Ireland, and we are therefore able to speak with some experience, both on the practicability of such a venture, and still more we are in a position to furnish facts and data, which must be of the greatest use to the Poor-law medical officers of England if they think well of drawing up a draft scheme.

In 1873 we addressed the Irish Medical Association upon the subject of a Poor-law Widow and Orphan Fund, but our data were imperfect, and we endeavoured to remedy this by collecting information from the Poor-law medical officers of Ireland. For this purposes a circular was issued to 1,019 medical officers, 218 of whom were connected with workhouses, the remainder with dispensaries. The question which we put was plain:—"Supposing that an annuity of £10 yearly for your widow, and £10 for each child surviving you, could be secured by a quarterly deduction of (say) 15s. from your salary, would you as far as you can at present judge, be disposed to consent to such deduction?"

To this inquiry we received 410 replies, and we have no doubt the responses would have been higher but for the action taken by a member of the Poor-law service. We need not now dwell upon this subject. Out of the 418 replies only 52 were in the negative, so that we fairly concluded, that if the details of a mature and approved scheme were laid before Poor-law medical officers, it would meet with almost universal acceptance. We obtained other information, which we will now *seriatim* examine.

Average Age of the Poor-law Medical Officers of Ireland.—We collected statistics on this point, and we have arranged

TABLE I.

AGE.	No. of Medical Officers at each age.	No. of their Wives.	Relative No. of Medical Officers for all Ireland.
25 to 35	176	107	450
35 to 45	65	46	166
45 to 55	49	55	125
55 to 65	75	34	192
65 and upwards	33	5	85
Age not given.	20	—	51
Total ...	418	247	1,019

our results in tabular form, from which some simple conclusions will be at once drawn, as that a considerable number of Poor-law medical officers retain their offices up to an advanced age, 70 to 80; from which it is reasonable to suppose, that if it were the right of medical officers to

Digitized by Google

claim superannuation after certain years of service, few would be disposed to retain, beyond sixty-five, the physically arduous duties of a dispensary.

We must now more minutely analyse the figures in this table.

Matrimonial and Paternal Conditions of Medical Officers.—Of the 418 medical officers who made returns, 252 had living wives, representing for all Ireland 614; 13 were married a second time, representing 31; and 127 were bachelors, representing 309. So that from the law of average we framed the matrimonial and paternal conditions of the whole Poor-law medical service of Ireland.

Number of Children.—The children, living or dead, of the 418 who replied, who had been married at any time, numbered 1,026, being for each man 2·45 children; but this cannot be taken to represent all the children who might come within the scope of the fund. The average number would be about 4·37 children.

Survivorship of Children.—On this point—a most important one in our scheme—we concluded that, for each subscriber who dies, an average of 1·50 children would fall on the fund. In the few special cases where the subscriber marries again, with a chance of a second family, provision will have to be made for such special cases, by requiring the subscriber to pay such a sum as would cover the risk. Such cases are few, viz., 31 for all Ireland.

Age at which Poor-law Medical Officers join the Service.—As it was part of our proposition that the medical officer shall commence his subscription to the fund immediately on his joining the service, whether he be married or not, it was essential to ascertain with accuracy the dates of first appointments. The average age of the medical officer at first joining we found to be 28·46 years. This number expressed the average of the whole number, but not the average of the great majority who join at a much earlier period. We consider it should be the great object of the administration of such a fund to induce medical officers to subscribe from the first day of their initiation to office. By doing so they would secure much greater advantages for themselves and their families, and be better able to afford the deductions from salary, which should be on a sliding scale—small for the medical officer who joins the fund on his entry to office, and large for the one who waits until he has already encumbered the fund with a wife and children. It would appear, however, that most medical men marry about the same time, for we found that while the average age at entering office was 28·46 years, the average age at marriage was 31·17.

Provisions already made by Poor-law Medical Officers for their Families.—In order to ascertain whether anything like an adequate provision for their families was possible or usual for Poor-law medical officers, and whether, therefore, a further provision for their wives and children was necessary, we requested each informant to state the amount of insurance effected on his life. We learned that 235 out of the whole number who made returns—nearly two-thirds of all—had effected no insurance whatever, and very many of these had wives and considerable families dependent on them. The average insurance on the lives of those who had insured was nominally £614. We imagine that this is greatly in excess of the sum available for the benefit of their families at their death, because it probably includes insurances effected as security for debts, to cover life interests in land, and various other legal purposes. A review of the returns which we have received makes this obvious, for we observed that while some few insurances were as high as £3,000, the vast majority were for insignicant sums, 90, or nearly one-half, being for £500 or less. It is unnecessary, therefore, to say that the widows and orphans of Poor-law medical officers in Ireland are to all intents without any dependence, in the way of insurance, in case of the death of the father of the family. It appears plain that Poor-law medical officers who possess no private property are, as a rule, compelled by the *res angusta domi to run their lives against their responsibilities*, and live in hope that they may survive, long enough, to rear their children to full age, and to make some little provision for their wives. The melancholy records of the Royal Medical Benevolent Fund Society show us how often this hope is unfulfilled, and how frequently the medical man, who has been unable to spare a yearly insurance premium from his narrow income, is taken by an early death from his helpless and dependent family. Perhaps some of the most distressing cases we never hear of, for there are sensitive natures who shrink from revealing, even to the eyes of their professional brethren, their poverty, and who become absorbed in the great ocean of life, living, or rather existing, in a manner inexplicable by our ordinary rules of political economy.

We have too many sad appeals for help in our medical journals—we will not say a word as to who is to blame for this—but we may point to the sad fact, as a stern proof of the necessity of providing while there is time.

We intend thoroughly to investigate the subject, and to present our readers with all our data, and we invite our Poor-law medical brethren to favour us with their opinions, and to offer us any suggestions they may think desirable. We have no direct personal interest in the question, and our sole desire is to fulfil the purposes, always kept in view by the *Medical Press and Circular*, of assisting in the elevation of the profession in all its branches, both in its moral, scientific, and pecuniary aspects.

RATIONAL CHEAP DIETARIES.—III.

After the foregoing considerations as to different foods and dietaries, it may be as well to review the present position of our food supplies. We shall, on looking over current prices, see that as of old, so now, the staple of the poor man's food must be bacon and cheese. But our modern physiological knowledge tells us how they must be prepared, and with what other articles combined. In Staffordshire bacon is fried in a pan, and then cheese is fried in the fat, and the whole eaten together with bread. This is far from an unpalatable dish, and has a high food value; but it is not likely to become fashionable even at the present prices of these two foods. But by combining fat bacon with some of the pulse tribe, and adding onions, a complete dietary is attained. Of course it is economical and agreeable to eat potatoes with such dishes. On the other hand, cooked combinations of cheese and farinaceous matters should be preceded by a vegetable soup, so as to provide the anti-scorbutic element. The use of hominy

Digitized by Google

must spread in this country, even if there exist prejudices against Indian corn. It is usually supposed that Indian corn is a pure starch almost; but this is a mistake. Reference to Pavy's well-known work on "Food," or to other like authorities, tells us that maize contains an amount of nitrogen equal to that in the best wheaten flour; while in fat it is richer even than oatmeal. Consequently as a cereal maize stands highest for actual food value. It is not adapted for making raised bread; but mixed with an equal quantity of wheat flour it can be so used economically. For pastry of all kinds, and indeed for anything for which wheat flour is used, except raised bread, maize may be substituted with advantage. Not only has it a higher food value than wheat flour, but Indian corn is at least 25 per cent. cheaper to buy. We are gradually losing our old prejudices against food of foreign origin, and the home wheat crop affects but little the price of bread; and as we have accustomed ourselves to the use of foreign flour, so, in time, we shall begin to use maize. The habit of having porridge to breakfast, especially for children, is returning to popularity, and for those with whom oatmeal disagrees hominy may be substituted. Especially is such form of breakfast to be indicated in the manufacturing districts, where the deterioration of the physique is so marked in consequence of the dietary adopted, of which tea and bread is the staple. Idleness on the part of housewives on the one hand, and the high wages women can earn in mills and other industries on the other, have led to a most vicious system of preparing food; and if the English race has to hold its own, a totally different plan must be adopted to that at present in vogue. Simple dishes, easily prepared, and which cannot readily be utterly spoiled by a little carelessness in their preparation, or ruined if the meal has to wait some time, alone are likely to meet with acceptance from the working classes. Dishes that require many culinary apparatuses are on the face of things not likely to be adopted. Then, for those somewhat above the artisan classes, but to whom cost is still an important consideration, the preparation of simple economical dishes is a matter of much interest. Men are much influenced by the preparation of their food, a remark which lays no claim to novelty; but the fact is often overlooked by women. The use of pudding is declining, whether because the fashion amongst men is to deride them, or because housewives will not take the trouble to prepare them properly, may not be affirmed. But puddings which contain quantities of fat finely divided may with advantage be re-introduced on our tables. The milk pudding made with tapioca, rice, hominy, or sago, and served up with stewed fruit, ought to be much more commonly in use than it is. Especially is this desirable for that unfortunate class of beings, viz., dyspeptics. These, whether "hand-workers" or "head-workers," are heavily handicapped in the struggle for existence. More money is required for their food; they can earn less with which to purchase it. In the readily digestible pulses they will find dishes they can eat; while the milk pudding and stewed fruit form a very suitable dietary for them. What is left of the milk pudding and stewed fruit from the dinner, may be eaten cold at breakfast; and many a dyspeptic who come down to the conventional fried bacon and eggs to breakfast with loathing rather than with appetite, will find in this cold food something at once attractive and digestible. We suffer terribly from our devotion to conventionality, and our food ceremoniousness is very trying to many. Why in the name of reason can we not have stewed or plain fruit on our breakfast tables in this country as is the custom elsewhere. It is pleasant to the palate, it is anti-scorbutic—an element usually wanting at the breakfast table—while it usually regulates the bowels. And now we can find fruits all the year round, thanks to the improved methods of tinning fruits. A look around Messrs. Thurber's, of New York, great wholesale store in London, is very comforting; the invalid and the dyspeptic would alike be gratified. Peaches, apricots, apples, grapes, &c., &c., are all there, with olives, tomatoes, capers, asparagus, &c.; there need be no lack of fruits and vegetables all the year round for those who desire them. With the increase of physiological knowledge on the one hand, and unlimited supplies of food at a low price coming in from abroad on the other, the dietary of the inhabitants of Great Britain may be profoundly modified, made at once attractive and nutritive; money may be saved, appetites and digestions improved, tempers sweetened, and tissues better nourished, if the housewife would only be induced to lend her ear to the charmer.

The season for evening readings is now upon us, and we conceive that many of the members of our profession, alike in towns and villages, might profitably deliver short lectures on the different articles of our food. The line adopted here might be utilised and developed. By doing so medical men might interest their wives in the subject and so improve their own dietaries; they might give much information which will be very acceptable to their neighbours. As a body the profession has taken the lead in calling attention to sanitary matters; we think they might add to their public usefulness by taking up the subject of cheap and rational dietaries, and so be of still further use to their fellow-creatures.

Notes on Current Topics.

The Army Medical Warrant.

We printed the week before last the revised scale of pay and pensions of army medical officers which the War Office has thought it wise to issue in anticipation of the competitive (?) examination announced simultaneously.

The military authorities have, however, kept back all that part of the new warrant which is conversant with the social and regimental position of the medical officer, and with the disabilities of which he has complained so loudly.

The scale of pay and emoluments is, we are glad to admit, a distinct amendment on the previous warrant, and *pro tanto* it will make the Queen's service more acceptable than it has recently been. But we beg to assure our military masters that they cannot buy the profession at this or any other money price which the nation would be content to pay.

Medical men have not held back from Her Majesty's Service because of insufficient payment, but because of

Digitized by Google

insufficient consideration for them in their position of officers. Indeed the pay receivable by a young surgeon on entering the service was always, if not liberal, at least moderately sufficient and quite tempting enough to have attracted candidates if there were nothing else to consider The profession has stood aloof because it would not be content with treatment less considerate than that accorded to its nominal equals in regimental status. The jealous unwillingness to accord to them their fair position in the regiment, has for years shown itself in small matters and from day to day we regret to say that we fear it still exists as strong as ever. The fact that the part of the new warrant which deals with this matter is now withheld, must, we fear, be interpreted as meaning that, even now, the combatant authorities cannot bring themselves to do the needed justice with a good grace, but are just as anxious to snub the doctor as ever they were. We hope we may be wrong in thus interpreting the suppression of one-half the warrant, but at least we shall not believe that the past policy is going to be reversed until we see Her Majesty's signature to a document which frees the medical officer from the liability to perennial snubbing.

We earnestly counsel students and surgeons to put no trust in promises of the faithlessness of which they have already had experience—to keep clear of the service until they know the whole of their bargain with the authorities—to examine every word of the contract before they make themselves liable to it. We can confidently assure students and surgeons that if the Army Medical Department can only charm a sufficient number of them into their net, the pen will, most probably, be drawn through all the concessions which we hear have been wrung from the department by the wise refusal of the profession to have anything to do with it. Let our profession only wait patiently a little longer, and they cannot fail to secure terms much more advantageous than have yet been conceded. It is only a question of a few months, a trial of strength between the jealousy of the combatants and the self-respect of the doctors, and we shall indeed feel humiliated if that self-respect gives way before the money bribe which the War Office has just promulgated.

Health of Dublin.

The deaths registered in the Dublin district during the week ending the 22nd represent an annual mortality of 38·0 in every 1,000 of the population. The average annual death-rate for the week in eight large town districts of Ireland (including Dublin), last week was 32·5. In London the death-rate was 25·4; in Glasgow, 20·7; and in Edinburgh, 16·8. In the Dublin district the deaths were 230. Forty-seven deaths from zymotic diseases were registered, being 11 over the average number for the corresponding week of the last ten years, and 4 more than in the week ending 15th inst.: they include 7 from small-pox, 2 from measles, 15 from scarlatina, 1 from croup, 2 from whooping-cough, 9 from fever (8 typhoid, and 1 simple continued fever), 1 from dysentery, 5 from diarrhœa, &c. The registered deaths from small-pox are 3 over the number for the week ending 15th inst., and are equal to the average number for five antecedent weeks. There were 26 new cases of this disease admitted into the Dublin hospitals last week, being 14 more than in the preceding week, and slightly in excess of the average weekly number for the current quarter; 12 patients were discharged during the week, 2 died, and 79 remained under treatment on Saturday last, against 67 on the previous Saturday. It will be seen that scarlatina continues prevalent, but the deaths are 4 under the high number in the week ending 15th inst. Sixteen new cases were received in the principal hospitals, being 2 over the average number in previous weeks of this quarter. Compared with the preceding week there was an increase in the number of typhoid fever cases admitted into the principal hospitals, and a decrease in cases of typhus and pneumonia.

The Ipswich Murder.

The convict Bedingfield, under sentence of death for murdering a woman at Ipswich, is exciting the interest of a number of people who are not satisfied that the evidence of guilt adduced at the trial is convincing of his having done the deed. In a recent letter the Vicar of St. Margaret's, Ipswich, makes a strong appeal on behalf of the accused man, and brings prominently forward the assertion made by a surgeon that the wound inflicted on the deceased woman is such as to make it impossible she could have spoken after its infliction. The larynx having been divided, speech would be no longer possible, as any one may prove who watches the endeavours to speak made by a patient on whom the operation for tracheotomy has been performed. If, as is asserted, the evidence to the effect that the woman had accused the prisoner was refused at the trial, and thus the refutation of the charge by the medical officer's evidence also rendered impossible, there would seem some reason sufficient to induce the reconsideration of the facts of the case. In a case of this kind the medical testimony has the most important bearings, and ought always to be received in detail, even though much of it may seem to have no direct bearing on the issue. In this instance it might have very materially modified the conclusions of the jury.

The Question of Antiseptics.

A paper read before the Clinical Society of London, last Friday, on a case of double hip-joint excision, and reported on another page, afforded an opportunity for the expression of some opinion on the value of antiseptic surgery. Mr. Bryant commenting on the paper read, implied that far too much was claimed on behalf of the antiseptic method, by its adherents; and he further charged the system with being blameable for instigating surgeons to the performance of operations which are intrinsically unjustifiable. The confidence felt in antiseptic dressings, he alleged, led many men to make incisions and exploratory operations in situations where, under the older *régime*, they would not dare to use the knife. He could not, either, sanction the assumption that antiseptic surgery was a modern invention, and thereby drew forth an indignant remonstrance from Mr. Croft, the author of the paper which was the basis of the discussion. This gentleman demanded to know if dipping a lump of cotton wool into an antiseptic solution, and swabbing a surface with it could be rightly termed "antiseptic treatment," and eloquently denounced those who would endeavour to detract in the least from the ternal claims of the founder of "Lis-

Digitized by Google

terism" on the gratitude of mankind. This, and this only, he declared could be held to deserve the confidence of the operator; and then only when every minute detail of treatment as set forth by its originator was scrupulously carried out. It is the glory of the system, he added, that it *does* permit the safe performance of operations impracticable except under its conditions; and far from being chargeable with evil results, or as inciting to needless interference, it had rendered the alleviation of suffering possible in innumerable instances where, without its aid, pain and suffering must have been permanently endured. It must be admitted that the weight of evidence adduced on this occasion did not tend to prove the unreality of the results attributed to antiseptic surgery, and some surprise may be excused on the part of those who regard the obstinate refusal of some surgeons to accept the apparent force of the arguments deducible from facts. One thing especially this discussion made clear; that, namely, the time has fully arrived when it is the imperative duty of Professor Lister to enforce in his own name the absolute certainty of his method, and add the weight of his personal testimony to the mass of evidence that has within the last few months been laboriously collected by a host of observers, to prove the incontestible nature of the truth he has disseminated. We have before had occasion to make this suggestion, and we insist yet more strongly that it is the duty of the eminent professor, who has given his name to the greatest surgical improvement of the century, to vindicate the association, and to silence the opposition that is being continually raised against the universal introduction of the antiseptic treatment of wounds.

English Winter Health Resorts.

In connection with our recent remarks on residence abroad in lung consolidation, a few remarks on one of our principal English winter resorts—Bournemouth—may not be out of place. Last winter was exceptional in severity and duration in all parts of Europe, if not of the world, and even at Cannes, Mentone, Nice, &c., it was severely felt. The cold period of December was the coldest but three which has been known at Greenwich for 107 years. Some particulars of the lowest temperature experienced at Bournemouth during this severe period, and a comparison of that with forty-five other English stations in given in a pamphlet by Dr. Compton, of Bournemouth, now before us. From this we learn that as regards mean lowest temperature on the eleven coldest days of December Ventnor stands first with 27·2°; Bournemouth second, 25·6°; Torquay third, 25·4°; Llandudno fourth, 25·1°. With respect to the actual minimum reached on any one of the days, Ventnor still comes first with 23·7°; Bournemouth second, 22 3°; Brighton third, 21·0°; Llandudno fourth, 20·7; Torquay comes sixth. For comparative winter warmth therefore, so far as it can be judged of from these statistics, Ventnor occupies the highest place, Bournemouth a very good second, and Torquay comes in a somewhat doubtful third.

There is another point, however, which is of great importance with respect to an invalid's residence, viz., dryness. In the second part of his paper Dr. Compton gives some remarks on the rain and snow fali of the last three months of last year. During that period in some parts of England snow fell on no less than fifty days. The smallest amount of rain and melted snow during the period was registered at Bournemouth, viz, 5·32 inches on 38 days, Liverpool comes next with 5·94 inches on 49 days. Truro suffered the greatest amount of rainfall, viz., 17·28 inches on 60 days. Ventnor, which stood first in the list as to warmth, comes 25th with respect to rain and snow fall—having had 8 99 inches on 53 days. Torquay which comes 31st, had 9·90 inches on 52 days. At Cannes 16·48 inches fell on 35 days, an amount greater than at any of the English stations but one. Bournemouth then seems to enjoy a considerably less rainfall than any of the other health resorts which at all approach it in temperature, and it has another advantage in the peculiar nature of its soil, by which the rain dries away almost as fast as it falls, so that exercise with dry feet is possible immediately after even heavy showers. Another important point respecting Bournemouth is its low death-rate, and its immunity from infectious or contagious disease. From the report of the medical officer of health it appears that during the whole of 1878 the number of adult deaths from infectious or contagious disease was *nil*. We shall hope to have the opportunity of publishing statistics of other home health resorts, and of drawing some definite conclusions from them.

Defibrinated Blood for Rectal Alimentation.

At a late meeting of the Therapeutical Society of New York, Dr. Andrew H. Smith, Chairman of the Committee on Restoratives, presented a report (*New York Medical Journal*, April, 1879) on this subject. From the facts before them the committee felt warranted in drawing the following conclusions:—

1. That defibrinated blood is admirably adapted for use for rectal alimentation.

2. That is doses of two to six ounces it is usually retained without any inconvenience, and is frequently so completely absorbed that very little trace of it can be discovered in the dejections.

3. That administered in this way once or twice a day, it produces in about one-third of the cases for the first few days more or less constipation of the bowels.

4. That in a small proportion of cases the constipation persists, and even becomes more decided the longer the enemata are continued.

5. That in a small percentage of cases irritability of the bowels attends its protracted use.

6. That it is a valuable aid to the stomach whenever the latter is inadequate to a complete nutrition of the system.

7. That its use is indicated in all cases not involving the large intestine, and requiring a tonic influence which cannot readily be obtained by remedies employed in the usual way.

8. That in favourable cases it is capable of giving an impulse to nutrition which is rarely if ever obtained from the employment of other remedies.

9. That its use is wholly unattended by danger.

The statistics of suicides in France, just issued, show nearly six thousand persons committed suicide last year.

The Abbey of Thelema and Salutland.

RABELAIS, whose book Voltaire called "un ramas des plus grossières ordures qu'un moine ivre puisse vomir," is read with profit in our days, and a higher appreciation shown of his writings than in the days of the philosopher of Ferney, and, as Walter Besant says, "Coleridge, Victor Hugo, Michelet, Kingsley—a whole chorus of noble voices has been raised in defence and praise of the man and his book." See "Foreign Classics for English Readers." We have heard lately of Salutland. How many have heard of the Abbey of Thelema—the prototype of the dream of Dr. Richardson? Rabelais was not all buffoon. The following description of his abbey proves this:—

Mr. Besant tells us that the Abbey of Thelema is one of the most graceful and most noble fancies that ever entered into the soul of man. It forms a fit pendant to the scheme of education which its founder drew up for a young prince. The Order of Thelema is a society composed entirely of young people, living together in the freedom of gentlehood, unrestricted by any conventional and useless rules. They are to learn, by watching the wishes and wants of each other, how to live; they are to be occupied all day in study, in manly exercises, or in the acquirement of womanly accomplishments; they are to be entirely free from the petty cares and anxieties of the ignoble life; they are to live in accordance with the laws of nature, and *are therefore to be exempt from disease.* The abbey itself is to be a miracle of architecture. It is to be the home of the highest expressions of art, refinement, and luxury, When the monks and sisters have learnt all that the society is able to teach, they may leave it, two by two, and go forth into the world, examples for all men and women to follow.

Land was given by Gargantua to Friar John to establish this monastery. The preliminaries being agreed upon, the building was at once commenced. In the description of the building Rabelais, who, like Victor Hugo, never touches a subject of which he is not master, has given so minute an account of a great and magnificent building, that architects have succeeded in reproducing the plans and elevations Rabelais had in his head.

Greater descriptive power has never been shown than so to set forth a building as to enable a draughtsman nearly three hundred and fifty years later, to represent on paper exactly such a building as the author pictured. Suffice it to say, that the abbey was conceived in the spirit of the greatest luxury and magnificence. Stately fountains, spacious galleries, tiltyards, riding-courts, theatres, swimming-baths, the garden of retreat or delight by the river side—a labyrinth, tennis and ball courts, orchards planted with fruit trees, a park filled with deer, butts for guns, crossbow and archery, stables, a falconry, a "venery"—where beagles and hounds were kept—and outside the abbey rows of houses in which dwelt, for the convenience of the fraternity, all sorts of handicraftsmen, such as goldsmiths, lapidaries, jewellers, embroiderers, tailors, gold drawers, velvet-weavers, tapestry-makers, upholsterers, and others who worked for the monks and nuns of the new order.

Cæsarian Section, with Removal of the Uterus and Ovaries.

IN the hope of diminishing the mortality after Cæsarian section, Parro, of Pavia, in May, 1876, proposed and practised successfully the ablation of the uterus and ovaries after the removal of the child. According to our contemporary, *La France Médicale*, the operation was favourably received by the Continental gynecologists; and Fovier, of Paris, in a recent article, stated that it had been, as far as he had been able to learn, performed thirty-three times, with the result of saving more than half the mothers. To these cases may now be added two more, which were reported to the Académie de Médecine on July 29 by M. Tarnier.

In the first case the operation was performed seven days after premature rupture of the membranes, at the eighth month, and four days after the death of the child. The child and the placenta were putrid, and the mother died three days afrer the operation of putrid infection. Delivery *per vias naturales* had been rendered impossible by the presence of a fibrous tumour, which filled the excavation. The second case was successful, and M. Tarnier, in presenting the patient to the Academy, remarked that the case was especially interesting, because the Cæsarian operation had not been successfully performed in Paris since 1787. In this case the operation was rendered necessary by rachitic deformity of the pelvis, which was so marked that cephalotripsy was impossible. The operation was performed the day the patient entered the maternity, but the membranes had ruptured three days before, and the child had been dead two days. The cervix was not dilated. After incision of the abdominal walls and uterus, and the removal of the child, the uterus and ovaries were drawn out of the wound, and a Cintrac's serre-nœud was applied at the junction of the body with the cervix. Above this serre-nœud, after the uterus and ovaries had been cut off, a transverse pin was placed, which was itself secured by a second wire ligature. The patient made an excellent recovery, the maximum temperature in the axilla being only 101 2 5th° Fahr. The wound was treated on the strictest antiseptic plan, and M. Tarnier is inclined to ascribe the successful result largely to this fact. He believes that the operation is not only justifiable, but that it is destined to take a front rank in surgery. It seems to him superior to simple Cæsarian section, because it does away with two of the dangers of the latter, viz., uterine hæmorrhage and peritonitis from escape of the lochia into the peritoneum. These elements of increased safety will more than counterbalance the objection, that the operation entails sterility on the patients. M. Tarnier dwelt urgently on the importance of having recourse to the operation early in appropriate cases, for the sake both of the child and the mother. He believed he was the first surgeon to perform Porro's operation in France, but this claim has been challenged by M. A. Fochier, Surgeon-in-Chief of the Charité, who states that he performed the operation in that hospital three weeks before the date of M. Tarnier's first operation. Dr. Storer, an American surgeon, is credited with having performed the first operation of this kind in 1868.

The Great Unpaid.

MAGISTRATES, or rather honorary justices of the peace, were called by the above name. We think doctors come under this heading, for they are to an enormous extent robbed of the value of their advice by the customs of society, by which they are expected to give gratuitous services.

There is a very sensible and straightforward letter in our Canadian contemporary, the *Lancet*, from which we shall make a short extract. An old and eminent surgeon writes to a young practitioner and gives him the following advice :—

"Having in a long time of practice, both from choice and necessity, done a good deal of gratuitous service, amounting to thousands of dollars, I have yet to find a single case where my charity work was appreciated. Those who pay nothing, always offset it by liberal abuse, which keeps away those who would pay.

"The man you write about may be a very worthy man; but if you were making a struggle to build a house, would he or anyone else work for you at reduced rates. It is the doctors themselves who allow their kind feelings to overrun their judgment, that are responsible for wholesale robbery, to which every doctor in the land is subjected. We deal with the afflicted, so does the undertaker; yet he is not expected to work for nothing. . .

"The people who pay are always grateful; the people who do not are, like other dead-heads, abusive, and always the most exacting and querulous. If ——— cannot pay for what might save his life, his friends or the public should. It is easier for the town to shoulder the cost than two or three poor devils, who had the bad luck to study physic.

"Now or never is the time to put ourselves on a par with other business men, and as we have the same losses, we must ask for the same gains."

Though we do not agree entirely with the above, yet we unhesitatingly think that the medical profession is imposed upon to an extent unknown in any other profession, and we consider that practitioners should limit the exercise of gratuitous services to really deserving cases. The working man, as he is represented, is a fraud. He can afford to pay proportionately as well as any other class. We have pauperised him for years, and he now looks upon our public hospitals as his own property, and gratuitous medical advice as a birthright.

Surgeon-Major Reynolds, V.C.

A REVOLVER and case, bearing the following inscription, will be presented to Surgeon-Major James Henry Reynolds, V.C., by his fellow-students and other friends in Trinity College, on the 17th December, 1879, when the degree of LL.D. (*honoris causa*) will be conferred on him by the University of Dublin :—"Presented to Surgeon-Major James Henry Reynolds, V.C., L.L.D., by his fellow-students and other friends in Trinity College, Dublin, at the Winter Commencement, 17th December, 1879, when the degree of LL.D. (*honoris causa*) was conferred on him by the University of Dublin."

International Congress of Hygiene.

THE third International Congress of Hygiene will take place at Turin, in April, 1880, under the patronage of the Italian Government. As at Brussels, in 1876, and at Paris, in 1878, the Congress will avoid political and religious discussions. At the Paris Congress last year there were eighteen nationalities represented, the Russian, German, and other governments appointing special delegates. It is anticipated that the forthcoming Congress will be equally well attended. Medical men will, of course, form the majority of the Congress, but chemists and veterinary surgeons are to have a place reserved for them. Architects and engineers are also invited, as with them to a large extent rests the application of the principles which men of science have discovered.

Dublin Pathological Society.

AT the inaugural meeting of the session, held on last Saturday week, the election of office bearers took place. The outgoing President, Mr. Edward Hamilton, was succeeded by Dr. E. H. Bennett, who, since the death of Dr. Robert Smith, has acted as secretary, in which office he is now succeeded by Dr. John William More, physician to the Meath Hospital. The following gentlemen were elected Vice-Presidents :—J. T. Banks, Samuel Gordon, Thomas Hayden, H. H. Head, George H. Kidd, T. Jolliffe Tufnell. In addition to outgoing Council, Drs. Barton, Reuben Harvey, Finney, and C. Nixon offered themselves for election, of whom the two first were elected, Dr. C. E. Fitzgerald being thus displaced. The Council now stands as follows :—John Kellock Barton, Anthony H. Corley, George F. Duffey, Arthur Wynne Foot, Reuben J. Harvey, Edward Hamilton, James Little, Thomas Evelyn Little, Robert M'Donnell, William Moore, John M. Purser, and William Stokes.

The Professorship of Practice of Medicine in Galway College.

DR. COLOHAN, the recently resigned professor, has been succeeded, after a very long interregnum, by Dr. John Isaac Lynham, who had been acting as *locum tenens* during the Professor's illness. Dr. Lynham is an M.Ch. of the Queen's University (1875), and formerly occupied the Chairs of Midwifery and Materia Medica.

Arsenical Poisoning.

WE have heard a great deal of late of the increasing dangers to health and life arising out of a more extensive use of arsenic in very many of our domestic manufactures. Horses and cattle have also, from recklessness and carelessness, been frequent sufferers from the same or similar deleterious agents. Last week a meeting was held of farmers and others interested in this question, in the Lincoln Corn Exchange, for the purpose of forming an association for preventing the administration of arsenic and other poisonous drugs to horses. This has been chiefly brought about by farmers in the district who have recently suffered very serious losses of horses and cattle. Several of the speakers mentioned cases in which horses had been killed by the administration of arsenic by their grooms and waggoners. The general conclusion came to was that chemists and druggists sold poisons recklessly, and therefore it was time some stringent measures with regard to their sale should be adopted. It was also said that much mischief was done by hawkers going into stables and offering poisonous drugs for sale to those in charge of horses.

Digitized by Google

Surely if this is so the Drugging of Animals Act, 1876, should be put in force, and a severe example made on conviction of the offender. It is quite evident, however, that some action must soon be taken to protect the public against the consequences arising from the use of arsenic and other poisonous agents ignorantly administered or recklessly employed in trade.

Dublin Obstetrical Society.

The first meeting of the 42nd session of the above Society took place on Saturday week in the College of Physicians, Kildare Street. There was a large attendance of members. Dr. Sinclair, Regius Professor of Midwifery, T.C.D., occupied the chair. Dr. Roe, Hon. Sec., read the annual report of the council, which was of a favourable character. The President then delivered the inaugural address, which dealt with the work of the Society and the history of the progress of obstetric medicine in Dublin. The following officers of the Society were elected for the session :—President, Dr. Sinclair ; Vice-Presidents, Dr. Churchill, Dr. Dill ; Treasurer, Dr. Cranny ; Secretary, Dr. Roe ; Committee, Dr. Denham, Dr. Johnson, Dr. Kidd, Dr. M'Clintock, Dr. J. R. Kirkpatrick. A vote of thanks to the President for his address brought the proceedings to a close.

In the *Deutsch Med. Woch.*, No. 34, Dr. Auerbach, of Berlin, recommends the use of balsam of Peru for pruritus as well as for itch, having found its use attended with the greatest success.

The forthcoming lectures in connection with the Brown Institution will be delivered by Dr. Greenfield at the University of London on December 17th, 18th, 19th, 22nd, 23rd, at 5.30 p.m. The subject will be "Recent Investigations on the Pathology of Infective and Contagious Diseases."

The Medical Society of the College of Physicians of Ireland will meet on Wednesday next at 8 o'clock at the College Hall, Kildare, when the following communications are set down for reading :—1. Dr. Purser : "Observations on the Occurrence of Indican in the Urine." 2. Dr. Walter Smith : To exhibit a specimen of Carcinoma of the Œsophagus.

The rates of mortality per 1,000 last week in the principal large towns of the United Kingdom were—Portsmouth 15, Sheffield 17, Edinburgh 17, Hull 18, Glasgow, 21, Oldham 21, Brighton 21, Newcastle-upon-Tyne 22, Plymouth 22, Leicester 22, Bradford 23, Bristol 23, Wolverhampton 24, Sunderland 24, Salford 24, Birmingham 25, Nottingham 25, London 25, Leeds 25, Norwich 26, Manchester 27, Liverpool 31, and the highest rate, Dublin, 38.

The Evening Meeting of the Pharmaceutical Society of Great Britain will be held on this day (Wednesday, December 3rd) at half-past eight precisely. Dr. Paul will call attention to, and exhibit, Standards to be used in verifying the Apothecaries' Weights and Measures used in trade. The following papers will be read :—"Tincture of Senega as an Emulsifying Agent," by Mr. H. Collier ; "A Method for the Volumetric Estimation of Arsenic Acid," by Mr. W. H. Naylor, F.C.S.

In the principal foreign cities the rates of mortality according to the most recent weekly returns were—in Bombay 33, Madras 40 ; Paris 25 ; Geneva 19 ; Brussels 23 ; Amsterdam 25, Rotterdam 21 ; The Hague 22 ; Copenhagen 35 ; Stockholm 24 ; Christiania 18 ; St. Petersburgh 30 ; Berlin 22, Hamburg 28, Dresden 18, Breslau 25, Munich 32 ; Vienna 24 ; Buda-Pesth 28 ; Rome 32, Naples 28, Turin 30 ; Alexandria 31 ; and New York 24 per 1,000 of the various populations. Small-pox caused 19 deaths in Paris.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

The Grierson Medical Bursary.—This bursary, given to the student who stands highest in the examination to be passed before entering the first winter session in medicine at the University of Edinburgh, has been awarded to Mr. Alexander Ferguson, M.C.S., Invergordon, who highly distinguished himself during his Arts curriculum.

Dumfries—Crichton Royal Institution.—Dr. Adam, late of the Middlesex County Asylum, has been appointed Medical Superintendent of this Institution, out of a large number of applicants, in room of Dr. Gilchrist, who recently resigned in consequence of the state of his health.

Health of Edinburgh.—During the week ending with Saturday, the 22nd November, there were 72 deaths registered in Edinburgh, and the rate of mortality was 17 per 1,000. No death from measles, diphtheria, or small-pox was recorded.

Edinburgh University Court.—At a meeting of the University Court held on the 24th November, *inter alia* arrangements under which Dr. Alleyne Nicholson acted as examiner in natural history for Professor Sir C. Wyville Thomson, and Dr. Cleghorn as examiner in botany for Professor Bayley Balfour, of Glasgow, at the October examinations, were reported by the Senatus and approved. The following gentlemen were recognised as teachers of medicine whose courses of instruction should qualify for graduation in medicine in the University, in terms of Ordinance No. 8, Sec. vi. :—Charles Bell, M.D., Lecturer on Midwifery, Edinburgh ; J. B. Buist, M.D., Lecturer on Pathology, Edinburgh ; and H. Aubery Husband, M.B., Lecturer on Medical Jurisprudence, Edinburgh.

Royal Edinburgh Hospital for Sick Children.—At a meeting of the directors of this hospital, held on the 24th November, Dr. R. J. Blair Cunninghame was elected one of the ordinary physicians to the hospital, in room of Dr. Linton, whose term of office has expired ; and Dr. John Playfair was appointed an extra-physician, to fill the vacancy caused by Dr. Cunninghame's promotion.

Death-rate in Glasgow.—The deaths in Glasgow for the week ending the 22nd November were at the rate of 21 per 1,000 per annum, against 19 in the preceding week, and 23, 21, and 29 in the corresponding periods of 1876, 1877, and 1878.

Glasgow Maternity Hospital.—The annual meeting of

Digitized by Google

the subscribers to this institution took place in the Religious Institution rooms on the 25th ult., Mr. Richard Grant, chairman, presiding. Mr. Arthur Forbes, Secretary, read the 45th annual report, which principally referred to the building of the new hospital, now being pushed forward with all rapidity. Though some handsome subscriptions had been given, the directors begged to remind the public of the great amount that was necessary to furnish the buildings, and they hoped they would give as liberally as they could. Dr. Tannahill read the annual medical report, which showed that 170 women had availed themselves of the benefits of the hospital during the past year, 78 of these being confined for the first time; and that 1,118 women had been attended at their own homes by the students and nurses presently training in the hospital. As compared with last year's numbers, this showed a decrease of 23 in the in-door patients, and an increase of 164 in the out-door.

Sermon to Medical Students.—The annual sermon under the auspices of the Edinburgh Medical Students' Christian Association was preached on the 23rd Nov. by the Rev. Professor Flint in St. George's Church. Dr. Flint maintained that it was clearly not generally desirable that the offices of preacher and physician should be confined in one person. The work of either a Minister of the Word or a healer of disease was certainly more than enough for any ordinary man in ordinary circumstances thoroughly to learn and efficiently to perform. The physician without benevolence and compassion was the same sort of anomaly as a minister without faith or piety; he was not a true member of the brotherhood to which he belonged, but was as much out of place there as would have been a coward at Sparta. He alluded to the narrowness chargeable to clergymen and physicians; and referring to the fact that the healing of disease was the only kind of operation in which Christ habitually displayed his miraculous power, the learned Professor said that had the Lord satisfied hunger as freely and on as large a scale. his miracles would really have tended on the whole to augment poverty and hunger, by leading the people to neglect to exert their faculties and to depend on charity (!) Reverentially carried to its legitimate conclusion, we may be permitted to inquire how a struggling, overcrowded, and consequently not over-scrupulous profession of physicians, would regard the indiscriminate curing of disease, either in India or elsewhere? If a man continued, said the Professor, to bestow alms on every beggar who applied to him, obviously be encouraged those whom he relieved to continue in the trade of begging, and others to enter it. Perfectly so, the grotesqueness of the reference to Christ by a Professor of Divinity notwithstanding—if any individual or institution afford *medical* relief "to every beggar" who applies, does he or it encourage those who are relieved thereby to "continue in the trade of begging," "and others equally to become beggars?' Dr. Flint then alluded to spurious charity, making an exception, however, in the case of Christ, whose charity "was not only a sincere charity, but did not defeat its own end!" Dealing with the alleged prevalence of materialism and atheism amongst medical men, it was contended that the chief cause was to be found in the physician's own mind and heart, and not in the subjects with which his profession compelled him to be conversant.

Registrar-General's Returns.—According to the Registrar-General's returns, the death-rate in the eight principal towns during the week ending with Saturday, the 22nd Nov., 1879, was 19·8 per 1,000 of the estimated population. This rate is 6·8 under that for the corresponding week of last year, but 1·1 above that for the previous week of the present year. The lowest mortality was recorded in Perth, viz., 13·7, and the highest in Aberdeen, viz., 26·1. The mortality from the seven most familiar zymotic diseases continues moderate, being at the rate of 3·3 per 1,000 of estimated population. There was an increase of deaths from scarlatina and whooping-cough in Glasgow.

Special.

FRANCE.

(FROM OUR OWN CORRESPONDENT.)

Paris, 26th Nov., 1879.—The series of surgical operations performed by the anæsthetic of M. Paul Bert (protoxyde of azote mixed with oxygen employed under pressure), interrupted by the vacation, have just been recommenced. In the first fortnight of November eight operations were performed by M. Labbé, surgeon to the Lariboisière in the theatre constructed by Dr. Fontaine for the employment (surgical and medical) of compressed air. In each case the success was complete. The advantages claimed for this new agent of M. Paul Bert are complete *innocuité*, dosage uniform, suppression of the period of excitement during the operation and vomiting after, rapid return to sensibility, &c.

At the meeting of the Medical Society of the 6th Arrondissement, Paris, Dr. Polaillon remarked *à propos* of the radical cure of hydrocele, that the tincture of iodine causes pain, sometimes very severe, brings on inflammation, often very intense, and requires rest and the employment of antiphlogistic measures in many cases. For the last eighteen months he has abandoned the tincture in favour of a solution of chloride of zinc, which causes but a very slight inflammation, which is followed by a prompt cure. M. Polaillon has employed this mode of treatment already eight times, and this is how he proceeds:—He takes an ordinary Pravaz syringe, containing about fifteen drops, and fills it with a solution of chloride of zinc (1 in 10), he introduces the needle into the scrotum and injects the liquid gently; the pain is trifling; a short time after the injection the scrotum retracts; the tumour seems to diminish in volume. The following three or four days there is a slight inflammation, but the patient may get up. The sub-inflammatory state lasts about ten days, and then diminishes; at the end of three weeks the cure is complete.

The Paris Society of Anthropology has just discerned the Godard prize, founded to reward the best work on Anthropology. The first prize (500 frs. and a gold medal) was awarded to Dr. Gustave Le Bon, for his memoire upon *Variations de Volume du Crane*. The conclusions he arrived at are, that the mean capacity of the skulls of the higher races exceed notably that of the lower, but that which constitutes really the superiority of one race over the other is the fact that the higher race contains a great many more voluminous skulls than the lower. The difference in volume increases as the race rises in the scale of civilisation.

For several years (says the *France Medicale*) Dr. Gourot uses with success the heat of the sun as a caustic for the destruction of nævus, warts, and other excrescences of the epidermis, and lately this mode of cauterising has been applied to ulcers and syphilitic condylomata. This method is distinguished by the absence of hæmorrhage, the slight pain, and the perfect limitation of the cicatrix. The instrument employed consists of a biconcave lens of two inches and a-half in diameter. As soon as the solar rays passing through the lens penetrated the skin the characteristic crisping of the burning could be heard, and the blood was seen to coagulate, and the vessels contract under its influence. This solar cauterisation has also been employed with success against palpebral granulations that had resisted every other means.

Correspondence.

THE INVENTION OF THE IMMERSION PARABOLOID.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of November 26th Dr. James Edmunds has chosen to disclose my name in connection with a confidential memorandum I wrote for him, and which he made use of in a communication to the *Quekett Journal* of April, 1878.

The purpose of this questionable act is evidently to screen himself from the charge of plagiarising Mr. Wenham's invention of the immersion paraboloid by making it appear that he had my declared support of his own claim to the invention at that date.

The origin of the memorandum can be told in a few words:—Dr. Edmunds appealed to me for a short paragraph in which to assert his right to the invention in opposition to Mr. Wenham. At the moment I knew nothing personally of either's claim; but, having Dr. Edmunds's assurance that he could substantiate his position, I jotted down a few words for his consideration. In so doing I took no responsibility on myself for the justice of his claim, but merely gave a rough draft of what I thought might be said on the supposition that he could prove his case.

As to the real question of priority in the invention. When, in July following, my attention was specially called to the matter, I examined the evidence, and concluded Dr. Edmunds to have been in error. I lost no time in communicating with him; and he then published in *Nature*, July 9, the letter quoted in your editorial note (*M. P. & C.* 19th inst., p. 448). That letter was understood by all immediately concerned as a distinct admission of Mr. Wenham's priority in the invention, and I think it will be so understood by every candid reader. It is, therefore, surprising to me that, after its publication, Dr. Edmunds should have again sought to affix his name in any shape or form to the apparatus. I can only regard his attempt to renew his claim as evidence of his radical want of candour.

Yours, &c., JOHN MAYALL, Jun.

224 Regent Street, W., 28th Nov., 1879.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Edmunds's letter in your last issue contains mis-statements disparaging both to others and myself, and I most strongly object to his malevolent interpretation of my short note in the previous number. That note was very hastily written. I much regret that anything from me should have appeared to cast a slur on the Royal Microscopical Society or its officers. When I said that "pirated inventions are constantly served up as something new, and that this is done in so barefaced a manner that I have been driven to send in my resignation," in this sentence I meant the term "barefaced" to apply to the *pirates* only. I most willingly endorse my opponent's remark concerning the President. We have been members of the Society for thirty years, and have seen nearly all the original pioneers of the science pass away, and there has never been a word of disagreement between us. The enormous amount of good work that the Society has accomplished from an early crude phase of the microscope till now, forbids the slightest imputation against its utility. I say this in all sincerity, because I have never experienced the "rebuffs" that Dr. Edmunds so gratuitously alleges; and no paper of mine has ever been rejected by the Council, and every paper that I have read before the meetings has met with a most cordial reception, certainly not treated as "meanderings." Every member of the Council, past or present, can confirm this, and instead of the mere official acceptance of my resignation that I had been led to expect it would receive, the President and Council unanimously expressed their regret at my determination, and requested that I should reconsider my decision.

As to the personal matter between Dr. Edmunds and myself, he first says my "friends (?) hope that I shall stick to my optical lathe." That I should never appear beyond it is no doubt the wish of persons of Dr. Edmunds's stamp, in order that any perfected ideas of mine may be freely appropriated by them. The sneer intended in this remark is lost upon me, as I happen to be rather proud of the self-acquired mechanical skill that enables me to carry ideas at once into practice. Had Dr. Edmunds learnt a little from the "optical lathe," it might have helped him to a more rational sort of immersion paraboloid than that he has adopted, and though in *Nature* he has accredited me with "a priority which he finds to be due to me," he now altogether ignores this statement, and in bad faith strives to attach his own name exclusively to the immersion paraboloid.

Dr. Edmunds next writes, with great self-assurance, that my experimental paraboloid was so cut off that it never could have done what is done by his own. It is quite impossible that Dr. Edmunds can know what I accomplished practically twenty-three years ago, and yet he continues in the same strain with equal disregard to fact—"Mr. Wenham's paraboloid is about as large as the top of the little finger, while mine is one and a-quarter inch in diameter." I happen still to possess the steel template from which the first flat-topped immersion paraboloid was made. As cut off at .06 inch below the external point of convergence or focus, the flat-top is exactly half-an-inch in diameter, the same as my drawing given in the paper of 1856 (*Q. J. M. S.*). Dr. Edmunds then says that my immersion paraboloid has not even been referred to in the catalogue of particular opticians, where he thinks, of all others, it should appear. I can only say that when I read papers I give a demonstration at the time, and do not seek for notoriety by afterwards exhibiting anywhere and everywhere, and distributing puffing handbills, as Dr. Edmunds describing his plagiarism has done. I have never endeavoured to force my name into opticians' catalogues, or to advertise any particular maker as the only one that constructs any instrument of mine. As the originator of paraboloid illuminators I may be credited with knowing something about them, and I affirm that a diameter of one and a-quarter inch is a most inconvenient and impractical size to adopt for the flat immersion top.

Finally, in order to meet Dr. Edmunds's very presumptuous assertion that my paraboloid of twenty years ago is "absurd," I gladly accept his challenge to a demonstration of what it will accomplish, and I am ready to show before the Quekett Club (where he first introduced the matter) the two forms of immersed paraboloid illustrated in my paper of 1856 (which shall be on the table at the same time), viz., the one now commonly used with a hollow hemispherical top, containing a nearly hemispherical lens, and the other exactly to my drawing of the flat-topped immersion paraboloid proper, to be shown under the same conditions of object and object-glass as that of Dr. Edmunds. I am confident of the general opinion that must be formed of the priority of my own practically realised invention.

Yours, &c.,

29th November, 1879. F. H. WENHAM.

Literature.

ROSCOE AND SCHORLEMMER'S CHEMISTRY. (a)

THIS volume forms the third instalment of a work on chemistry of which we have previously had occasion to speak very highly. Having at that time alluded to the special features of Messrs. Roscoe and Schorlemmer's method of treating the metals and non-metals, it is not necessary to touch on that point in noticing the present volume. Suffice it to say that those metals not described in the first part of Vol. II., viz., the metals of the iron, chromium, tin, antimony, and gold groups, are in the present part described in a manner in no way inferior to their predecessors, whilst the hundred pages devoted to "iron" contain, we believe, more recent and reliable information than has been heretofore gathered into so small a compass, or rendered clear by equally good engravings.

On page 465 of this volume the last of the metals is described, and with it the task of writing the chemical history of some sixty elements comes to an end. To say all that is important concerning so many substances, and yet maintain the work within reasonable limits, called for

(a) "A Treatise on Chemistry." Vol. II. Metals, Part II, By Professors Roscoe and Schorlemmer. Macmillan and Co., London.

Digitized by Google

a terse and concise style of writing, and a great power of condensation; and these have not been wanted. The volume is completed by chapters on Spectrum Analysis, the natural arrangements of the elements, and the condensation of gases, finishing with an index with more than a thousand references.

In the chapter on Spectrum Analysis we have conciseness carried to excess. As would be expected from so eminent a spectroscopist as Professor Roscoe, that which is written is good and practical, but it does not go far enough. It is scarcely fair to so important a subject to "shelve" it with one-third the space allotted to the single metal "iron." Condensation, which is so admirable a quality when applied to the routine work of describing chemical substances, has a double disadvantage when applied to so novel and so extended a subject as Spectrum Analysis, as the writer has both to cut down the explanatory matter and leave out the details. The first renders the subject difficult to follow by those previously ignorant, and the second renders the account too elementary for such as are already initiated. The first class of students, for example, would perhaps have been better for some intelligible maps of spectra (of which there are many, coloured and otherwise, to be found in Professor Roscoe's special work on this subject), while the advanced reader would think that an appliance like Rutherford's "Diffraction Grating," which, as a substitute for a series of expensive prisms, has proved so serviceable, should at least have been mentioned, and that the paragraph 678 on Variation in Spectra should have been amplified fourfold. In our opinion ten to twenty more pages of matter which Dr. Roscoe knows so well how to write would have more than doubled the value of this article.

Before quitting spectroscopy it may be desirable to draw attention to the discrepancy between the following extracts, the first from page 490 of the book, the second from Mr. Lockyer's paper to the Royal Society in March last.

Dr. Roscoe writes:—"Lockyer has come to the conclusion that most, if not all, of the cases of supposed coincidences between the lines of different metals are to be explained by the presence of an impurity common to both."

Mr. Lockyer says he has in an appended table "discussed in each case the possibility or impossibility of such coincidences having arisen from the presence of an impurity. In *a large number of cases the coincidences cannot be ascribed to the existence of impurities.* In many cases, it is true, the coincidences *may* arise from the presence of impurities, but this is by no means a proof that they do so. Indeed, it does not appear to have struck all who have considered this question that, as I have before shown, the presence of B existing with A as an impurity, and in A as a *base*, will, up to a certain point, give the same results; and the ascribing of lines, therefore, to impurities without a demonstration of the impurity, is an unscientific proceeding."

The following paragraph is, we think, sufficiently interesting to bear extraction, the metal referred to being that for which M. Lecocq de Boisbaudran receives this year the Davy Medal of the Royal Society:—

"Mendelejeff, a Russian chemist, has from certain theoretical consideration prophesied the existence of certain elementary substances at present unknown. Of one of these, 'ekaluminium,' as he calls it, Mendelejeff says:—

"'In its properties it stands between zinc and ekaillicon on the one hand, and between aluminium and indium on the other. Like the latter, it forms a sesquioxide; its atomic weight is about 68, its specific gravity about 6·0, and its atomic volume approaches 11·5.'

"These predictions have been verified in a most remarkable manner. Ekaluminium turns out to be Lecocq de Boisbaudran's gallium, which has an atomic weight of 69·8, a specific gravity of 5·9, and an atomic volume of 11·8. Whether the other predictions will prove equally successful time alone can show."

Royal College of Surgeons of England.—The following gentlemen, having passed the required examination for diploma, were admitted members of the College at a meeting of the Court of Examiners on Nov. 20th.

Allen, T. W. James, Louth.
Bulteel, Marcus Henry.
Cock, John.
Jones, Arthur Henry.

Wooldridge, Leonard Charles

Extracts of Meat and Chemical Analyses.—Not only Liebig Company's, but most other extracts, have been subjected to chemical analysis, and it has been found that, the exception of a considerable difference in concentration consequent contents of water—the main component part all were more or less similar, but the main feature of the Bentos extract, according to Baron Liebig's own judgment its fine flavour and perfect clearness when dissolved in w as compared with an unpleasant flavour, either burnt or o wise, and a want of clearness, which tell against so m other extracts. Chemical analysis is entirely insufficien prove the superior flavour and virtue of wine, and it is equ impossible by it to establish a similar comparison between "extracts of meat." The fact that Fray Bentos extract almost the monopoly of the market clearly shows that public are convinced of its superiority, and this is still m apparent when we state that other meat extracts are below the Company's price, and yet meet but a limited s The Liebig Company's Extract is tested by the chemist a establishment at Fray Bentos, and again on its arrival in A werp, and should it contain more than twenty-one per cent water it is not allowed to be sent away from the Compan depôt. As a rule it is found to have less than seventeen cent. of water and more than sixty per cent. of matter solu in alcohol of eighty degrees of strength.—*Land and Wate*

Royal Warrant.—The Army Medical Department. Warrant on the subject of the Army Medical Departm reached us yesterday from the War Office, of which we now only give the following brief summary. It divides officers into two classes, those who entered before the 29th April, 1876, and those who have joined after that date. specifies the daily rate of pay which each class is to receiv the various ranks from surgeon to surgeon-general, and s the charge pay. In future every candidate for appointm in the Army Medical Department must possess two diplom or licences recognised by the General Medical Council, one practise medicine and the other surgery, and must be reg tered under the Medical Act in force in the United Kingd at the time of his appointment. A candidate must not exce the age of 28 years on appointment as a surgeon on probati A public and open competition will be held twice in the ye for the admission of qualified candidates as probationers. surgeon on probation will, on appointment, be sent to soc large station for instruction in Ambulance and Hospital Cor duties until the commencement of the next course of study the Army Medical School. A medical officer, after completi ten years' service, may be permitted to retire on a gratuity pension. Any officer of class A who shall voluntarily reti before the age of 55 years shall be liable to be called upo to serve, in a case of national emergency, in a rank not low than that from which he shall retire, until he shall complet the age of 55. On the completion of ten years' commis sioned service, unless he be specially selected for further em ployment in the Army Medical Department, or if he be un willing to continue to serve therein, the services of a surgeo of class B shall be dispensed with, and he shall be entitled t receive in lieu of all pension or retirement, pension for wounds excepted, the sum of £1,000.

NOTICES TO CORRESPONDENTS.

READING CASES.—Cloth board cases, gilt-lettered, containing 2 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR, can now be had at either office of this Journal, price 2s. 6d. The post regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and fit after it has passed through the post.

LUNACY CERTIFICATES.

1. Is it not competent for a *private* medical practitioner—in the case of lunacy of *one of his patients*—to certify as to the state of the person before his removal to the asylum, *without* calling in the aid of the dispensary medical officer, particularly when the friends of the patient wish it?

2. Are the magistrates *bound* to accept his evidence as sufficient, and do they run *any risk* by accepting the evidence of the private practitioner?

3. If they accept the evidence of the private practitioner, are they justified in refusing to certify for his fee, even though he might be paid by the friends of the patient?

4. I assume in the above case that a dispensary medical officer *could* have been procured. AN INTERESTED ONE.

[1. Perfectly competent. The dispensary medical officer is only indicated as to be sent for by the magistrates in case of a dangerous lunatic; but if the case is one coming under sec. 10 of the Dangerous Lunatics Act, the patient being apprehended by the police and brought before the magistrate, then the dispensary doctor is the only recognised certifier. 2. The magistrate is not *bound* to accept the evidence of the dispensary medical officer, or of any other practitioner; but the patient would be illegally confined if sent to an asylum without that evidence. 3. Quite justified in refusing to certify for a dispensary medical officer, but he can recognise no other.—ED.]

MR. CROFT.—Your note has been handed to the gentleman named.

SURGEON-MAJOR CURRAN, Warrington.—Your letter on "Some Quasi-Medical Popular Fallacies and Beliefs" shall appear, if possible, in our next.

ERRATUM.—In Mr. Dolan's paper, "On Pauperism and Drink," last number, bottom of page 453, "Dr. Webster's statistics are *reported* by Dr. Orme Dudfield," should read are *disputed* by, &c.

A NEW METHOD OF GETTING CHILDREN VACCINATED.

A CORRESPONDENT writes:—A few days ago I was spending the evening with an hospitable P.P., about eight miles from my residence; in the course of the evening I was handed a red ticket to go and see a child about two miles further on. Arrived there, and asked what was wrong with the child: will you credit it—they simply wanted to get it vaccinated, and thought the present too good an opportunity to be lost.

[The medical officer may refuse to vaccinate under such circumstances, inasmuch as the red ticket requires nothing from him but advice and medicine.—ED.]

G. A. O'C. writes:—I have examined two supposed lunatics within the last three months, and because I could not conscientiously certify them dangerous I received no fee. I have attended at petty sessions for correction of errors, and am barely allowed mileage.

[Under sec. 14 of 38 and 39 Vic., cap. 67 (page 494, "Irish Medical Directory"), "it shall be lawful for any two justices causing any person to be examined by any medical officer, if they think fit to do so, to make an order for 'reasonable remuneration,' and for the payment of all other reasonable expenses not exceeding in the whole £2." Thus it will be seen that (*a*) the medical officer is morally entitled to his fee whether he certifies the lunatic or not; (*b*) that he is also entitled to all other reasonable expenses; but (*c*) that the payment is altogether in the discretion of the magistrates.—ED.]

JUSTITIA.—Our protest lies against abuse of Government patronage, not against medical men who hold more offices than one, of whom we don't complain as long as they can do their work. Therefore we must decline the letter.

DR. PEARSE, Plymouth.—"Case of Scarlet Fever or Diphtheria" received.

DR. HARBINSON, Lancaster County Asylum.—We shall be happy to get the engravings done to illustrate your paper, which is one of rather unusual interest.

FAIR PLAY.—Your note sent for publication mentions no specific grievance or charge; your "private" note accompanying it is more to the point. We think it is a case in which there is no hope of redress, unless you boldly state your complaint and append your name thereto.

LE DR. CORU, Buenos Ayres.—Thanks; we cannot further increase our already large Exchange List.

NE EXEAT.—A correspondent with this signature writes to thank us for the insertion of Dr. Hoggan's letter exposing the St. John's Hospital family party as a warning to the charitably disposed. As our correspondent does not send his name we cannot—in accordance with our rule—insert his communication, which is held over for compliance therewith, not necessarily for publication, but as evidence of good faith.

PSEUDO-MEDICAL DEGREES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Your valued correspondent's anecdote is a really amusing one, but, unfortunately, it is just a little old. I have read it in print before, *verbatim et literatim*. I did not exactly believe it then, nor do I now, although it is semi-seriously reproduced in your columns from a "valued," but, at the same time, anonymous correspondent. As the affairs of the university in question do not concern me in any way I am unable to say whether degrees in theology, law, and medicine were all *distributed* after the same fashion there; but I assume that they were. Truth therefore compels me to say that I have known a few "smart" men in my time who could not obtain the M.D. at that university by the payment of twenty-five or even fifty pounds, because they could not pass the prescribed examination. Nearly twenty years ago I was intimately acquainted with a legally qualified gentleman, whose ambition it was to write M.D. after his name. By men who knew their profession it was admitted that he knew it also; and, moreover, he was moderately well-read in Greek and Latin classics. This gentleman essayed to obtain that Northern M.D. at least three times, and was "plucked" each time. No reason was assigned by the examiners for the "plucking;" but on taking notes between ourselves this gentleman and I agreed that he failed alone in his English spelling. So much for "Saunders's" chance of being made a doctor, if not even for his master's chance too.

I am, Sir, very truly yours,
THE AUTHOR OF "MEDICAL MEN AND MANNERS."

Nov. 28, 1879.

HARVEIAN SOCIETY.—On Thursday, Dec. 4, at 8½ p.m., Harveian Lectures: Mr. Edmund Owen, "On Certain Practical Points in connection with the Surgery of Childhood."

OBSTETRICAL SOCIETY OF LONDON.—This evening (Wednesday), Dec. 3, Specimens: Ruptured Fallopian Tube, by Dr. Godson; Menstrual Decidua, &c., by Dr. Galabin; Milk Gelatinous Cord, by Dr. Cleveland; Uterus removed by Hysterotomy, Ovum Forceps, and other Instruments, by Dr. Heywood Smith.—Paper: "Report on Transfusion of Blood," by Prof. Schäfer.

VACANCIES.

Belrothery Union Workhouse.—Medical Officer. Salary, £90, and £10 as Consulting Sanitary Officer. Election, Dec. 15.

Dunfanaghy Union, Cross Roads Dispensary.—Medical Officer. Salary, £100, with fees, and £10 as Sanitary Officer. Election, Dec. 17.

Melton Mowbray Union.—Medical Officer for the Wymond Lane District. Salary, £12, with fees extra. Applications to the Clerk of the Union before Dec. 17.

Monaghan County Fever Hospital.—Medical Officer. Salary, £50. Election, Dec. 3.

Mere Union, Wilts.—Medical Officer of Health. Salary, £45. Also Medical Officer to the Workhouse. Salary, £10. Also Medical Officer for the Second District of the Union. Salary, £105. Applications to the Clerk of the Union.

Nottingham Borough Lunatic Asylum.—Medical Superintendent. Salary, £450. Applications to "The Chairman of the Committee of Visitors" on or before Dec. 16.

Oughterard Union, Lettermore Dispensary.—Medical Officer. Salary, £100, with fees, and Sanitary Salary. Election not fixed.

Wolverhampton Union.—Medical Officer for the Wednesfield District. Salary, £80. Applications to the Clerk, 49 Snow Hill, Wolverhampton, before Dec. 11.

APPOINTMENTS.

BOOTH, T. C., M.R.C.S.E., L.R.C.P.Ed., House Surgeon to the Oldham Infirmary.

BUTLER, G. H., L.R.C.P.L., M.R.C.S.E., House Surgeon to the Westminster Hospital.

DENNING, F. A., L.R.C.S.I., Apothecary to the Sligo Dispensary, Sligo Union.

GEORGE, A. B., L.R.C.P.Ed., M.R.C.S.E., Medical Officer for the District and Workhouse of the Whitchurch Union, Salop.

GRAY, J. A., M.A., M.B., C.M., Assistant to the Professor of Medical Jurisprudence, Edinburgh University.

HAMILTON, S. G., L.R.C.P.Ed., M.R.C.S.E., House Physician to Westminster Hospital.

KERIGAN, L., L.R.C.S.I., Medical Attendant to the Royal Irish Constabulary, Castletown and Streamstown, co. Westmeath.

LUNN, J. R., L.R.C.P., M.R.C.S., Assistant House Physician to St Thomas's Hospital.

LYNHAM, J. I., M.D., M.Ch. Q.U.I., Professor of the Practice of Medicine at Queen's College, Galway.

MYLES, G., L.R.C.P.Ed., L.R.C.S.Ed., a Surgeon to Barrington's Hospital and City of Limerick Infirmary.

O'HAGAN, P. J., L.K.Q.C.P.I. & L.M., L.R.C.S.I., Medical Officer and Medical Officer of Health for the Castlebellingham Dispensary District of the Ardee Union, co. Louth.

RUTHERFORD, R. L., L.K.Q.C.P.I., Assistant Medical Officer to the Durham County Lunatic Asylum.

SHARKEY, S. J., M.B., an Assistant Physician to St. Thomas's Hospital.

SKINNER, C. G. L., M.D., Medical Officer for the Blackley &c. District and the Workhouse of the Prestwich Union, Lancashire.

WARD, W. J. C., L.R.C.P.Ed., M.R.C.S.E., Medical Officer of Health for the Harrogate Urban Sanitary District.

WATSON, E. J., L.S.A.L., House Surgeon to the North Shields and Tynemouth Dispensary.

ARMY MEDICAL DEPARTMENT.—Surgeon-Major W. A. White, M.D. lately in medical charge of the Dublin Military Prison at Harbour Hill has retired on half-pay with the honorary rank of Deputy Surgeon General.

Births.

COLLINS.—On Nov. 24, at 72 Cadogan Place, London, the wife of W Maunsell Collins, M.D., Scots Guards, of a son.

KING.—On Nov. 17, at Ambleside, Westmoreland, the wife of W. More King, M.R.C.S., of a son.

MURPHY.—On Nov. 18, at Tranmere, co. Waterford, the wife of Surgeon-Major Murphy, of a son.

Deaths.

BROCK.—On Nov. 27, at 22 Lower Mount Street, Dublin, Edward John Brock, L.A.H.

COATES.—On Nov. 24, at Portumna, co. Galway, Samuel Coates, M.D. late Medical Officer, Portumna Dispensary.

CORRIE.—On Nov. 18, at Grafton House, Leeds, James Johnstone Corrie M.R.C.S.E.

GREALY.—At Carraroe, co. Galway, John Grealy, L.R.C.P.Ed., Medical Officer, Lettermore Dispensary.

HUNT.—On Nov. 26, at Herne Bay, Thomas Hunt, F.R.C.S., aged 81 late of Dorset Square, London.

JESSETT.—On Nov. 11, at Sheffield, George Jessett, Surgeon, aged 63.

ROBERTSON.—On Nov. 10, at Tredegar, Alexander Robertson, M.D.

WALKER.—On Nov. 22, at Holland Road, Kensington, Surgeon-Major George W. Walker, late of the Madras Medical Service.

EVANS'S EXTRACT OF MALT.

PROFESSOR ATTFIELD, PH.D., F.C.S. (Professor of Chemistry to the Pharmaceutical Society of Great Britain, Nov. 1872), writes:—"Evans' Extract is incomparably more valuable than any preparation of malt hitherto offered to the Public."

PROFESSOR TICHBORNE writes:—"Other preparations of this class which I have examined, on evaporation, yielded only 36 grains of extractive to the fluid ounce, whilst yours contains 101·5 grains.

Dr. APJOHN writes:—"Of these constituents the most remarkable are those which *include Nitrogen*, the amount of which is usually large—reaching, as it does, nearly 5 per cent. The *Ferruginic* compounds in an ounce of it weigh 22·32 grains, and the analogous compounds in an ounce of beef-steak 98·43. Hence, weight for weight, the *alimentary value* of the Extract is very nearly one-quarter that of the beef-steak. It is, therefore, *nutritious in a high degree, and being, no doubt easy of assimilation, it must constitute a useful supplementary food in cases of debility and weak digestion.*"

EVANS'S SOLID EXTRACT OF MALT is also prepared with the following combinations:—

Malt with Quinine and Iron, Pepsine, Parrishes' Chemical Food, Hypophosphites, Cod Liver Oil.

EXTRACT OF MALT—"EVANS'S" possesses the power of producing a perfect emulsion with Cod Liver Oil, and in his state the taste of the Cod-Liver Oil is more perfectly concealed than can be accomplished by any other known process.

PREPARED ONLY BY **JOHN EVANS, State Apothecary,**

Chemist to H.R.H. the Prince of Wales, H.R.H. the Duke of Cornaught, and His Grace the Duke of Marlborough, K.G.

SQUIRE'S DIALYSED IRON.

LIQUOR FERRI DIALYSATUS (SQUIRE).

(Introduced by P. & P. W. SQUIRE in 1869.)

A neutral and almost tasteless Solution of Peroxide of Iron in the colloid form, prepared by dialysis. Each fluid drachm contains 2 grs. of Peroxide of Iron. Dose—10 to 30 minims.

SYRUP OF DIALYSED IRON (SQUIRE).

Dose—A teaspoonful.

PARRISH'S CHEMICAL FOOD (SQUIRE).

As prepared by PARRISH, of Philadelphia.

For convenience and security, these preparations are supplied in 4-oz., 8-oz., and 1-lb. bottles. Each bottle bears the name "SQUIRE" on the seal and label.

P. & P. W. SQUIRE, 277 OXFORD STREET, LONDON.

IRISH POOR-LAW INTELLIGENCE.

IRISH MEDICAL ASSOCIATION.

Royal College of Surgeons, Dublin.

COLONEL KING HARMAN, M.P., D.L.

SIR,—The attention of the Council of the Irish Medical Association has been directed to a report of the proceedings of the Boyle Board of Guardians contained in the *Roscommon Herald*, in the course of which you, as chairman, are reported to have stated in communicating the result of an interview had by you with the President of the L. G. B. for Ireland, that "the reason" the board of guardians had proposed a reduction of the salaries of their medical officers of health, was that these officers "were not doing any work for the money." You are also reported to have stated your opinion that the dispensary medical officers "cannot do the duty. It is a work that should never have been thrown on them," because they "might have to report their own patients;" and finally you are set down as having stated that "all the authorities of the L. G. B. were then called out, and they all agreed" in that opinion.

The Council of the Irish Medical Association, upon the assumption that your remarks have been correctly reported, learn with much regret that a gentleman occupying your legislative and administrative position and possessing so much personal influence, should entertain a view so prejudicial to the interests of the poor-law medical officers of Ireland, and should express those views in public, and in your official capacity, without—as the Council believe—a full knowledge of the facts. The Council, moreover, desire me to express their great surprise that the authorities of the L. G. B., if they have spoken as reported, should think it consistent with their duty to depreciate the administrative efficiency of the large and important body of medical officers who act under their control, and for whose unsatisfactory performance of duty (if such existed), the board itself would be directly responsible.

The Council consider it necessary, in the interests of the Poor-law medical officers of Ireland, to meet at once the statements to which I have referred with a direct and emphatic impeachment; and they propose to show, *First*, that the medical sanitary officers have always been fully competent for the efficient discharge of their duty, and anxious to be permitted to do their work honestly, and without regard to their personal interests, and—as a matter of fact—did perform their part of the sanitary duty with great energy until compelled to cease from their zeal by the hindrances and discouragements offered to them by the boards of guardians, and by the L. G. B. *Secondly*, That the decadence of the Irish Public Health System has been the natural result of the course adopted by both these authorities, and is, in no respect, chargeable against the medical officers, upon whom the guardians now propose to visit their own *laches*.

It may be well, at the outset, to remind you that the sanitary office was not sought for by the medical profession; that it was forced upon them without a question asked as to their disposition for it; and that, as a fact, the imposition of its duties was most irksome to many medical officers, and was loudly complained of; and you will probably concur that when unsought-for functions are arbitrarily put upon any class of persons, it is at least reasonable that they should be liberally remunerated. The first step, however, in the series which has now culminated in the second breakdown of the Public Health System, was the order issued by the L. G. B. to the sanitary authorities not to pay to any dispensary medical officer for sanitary duty more than one-fourth of his dispensary salary, a suggestion of which those authorities availed themselves by voting remuneration, which the Council can only characterise as ridiculous. The average salary of all the medical officers of health in Ireland in 1876, two years after the passing of the Act, was under £18 a-year for the performance of duties analogous to those for which English medical health officers received a much larger sum. But this refusal of reasonable payments was not the only discouragement with which the medical officers of health had to contend, for they were met, as a general rule, with the open or covert hostility of the sanitary authorities who had been trusted by Parliament to promote sanitation, and by the coldness of the L. G. B. to all their complaints. Their reports and suggestions as to sanitary improvements, drawn up at much trouble and after unpleasant inspections, were, in a great majority of instances, wholly disregarded, marked "read," or indefinitely postponed, while the L. G. B., in consequence of its own refusal to provide inspectorial sanitary supervision, was completely in the dark as to the existence of the nuisances in question, and the attitude of the individual Sanitary Authority respecting those nuisances, and, therefore, was unable and unwilling to aid the medical officer in his efforts for improvement. The complaints and remonstrances of many of the medical officers of health, then and since, found their expression in the quarterly returns made by them to the Registrar-General, from which excerpts are regularly published, and you will there find abundant proof that medical officers were not backward in bringing the shortcomings of the public health system and the deplorable sanitary state of Ireland under official notice, although the great majority of such officers did not feel it their duty to express their views on the subject to any department other than the sanitary authority. If those representations were, as they unquestionably were, utterly ignored by the L. G. B. and the Sanitary Authorities, the fault lies with those bodies. If, under these circumstances, the activity of the medical officers was relaxed, who is to blame? That these officers are not responsible, that in spite of all impediments they did their duty cheerfully and jealously, is proved beyond doubt by the Parliamentary return made on the motion of Dr. O'Leary,

Digitized by Google

M.P., on the 21st of March, 1878. By reference to which you will find that, in the first year of the operation of the Act of 1874, the medical officers made nearly 26,000 reports, or 32 reports per man. In the next year there was, in consequence of the way these reports were treated, a falling off of 56 per cent. in the number, which dropped to about 11,000, or 14 reports per man, and, in the third year, from similar causes, a further reduction to 9,000, or 11 reports per man. It should be remembered that the number of reports bears no proportion to the sanitary work done, inasmuch as all medical officers effect their object as much as possible by remonstrance and threats, and do not report the nuisances to the guardians until they cannot help doing so.

The Council have thus endeavoured to show the injustice and inaccuracy of your statement that the sanitary medical officers were not "doing any work for the money," and "could not do the work," in which view it is said the L. G. B. concurs. In conclusion, they desire to point out that the course now proposed by the Boyle guardians and other sanitary authorities can have but one effect, *i.e.*, to make the sanitary organisation of Ireland less and less efficient, and the public health of the country worse and worse. No employer of labour in any walk of life can get more work than he pays for, and it may be safely assumed that the less the medical officers are paid the less energy they will expend on their duties, and the greater the proportion of the work which will remain undone. If it be ever really desired that the sanitation of Ireland shall be improved, it can be readily done. Let the L. G. B. provide itself with the means (which it has never pretended to possess) of knowing which sanitary authorities and which medical officers are honestly doing their duty. Those means this Association has, in vain, exercised all its influence to procure, while the Government has resisted every such proposition. When such proper and essential supervision is provided, then let the medical officers of health be impelled to energetic action by the L. G. B., *and be paid what is reasonable and fair, and no more*, for their work, and let the Sanitary Authorities be so stimulated to work, and held accountable for disregard of their part of the duty.

If this be ever done, and if afterwards, it appears that the medical officers cannot or will not work, they will then, and not until then, deserve to be held responsible for failure.

I am, yours, &c., J. W. M.

CORRESPONDENCE.

SUPERANNUATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have just read the letter of "One who receives, &c," and I imagine the grim smile with which the respected secretary of the Irish Medical Association must peruse one sentence in it—"I don't think there would be any difficulty in getting every Poor-law medical officer to sign this and subscribe at the same time half-a-guinea to the Association." No doubt "the best hurler is the man on the ditch!" and it is just possible that, notwithstanding the confident tone of the writer of this letter, the "proper way to set to work" to make "every man in Ireland a subscriber to the Association" is awaiting the Greek Kalends for its discovery. However that may be, the Association is at present entering with earnestness on a very important work—that of obtaining compulsory superannuation and the payment of half the amount of the retiring allowances out of the Treasury funds. The matter is such an important one that I must crave a little space to put forward the claims of medical officers to early superannuation, leaving it to another occasion to point out the importance to guardians to have half the superannuations paid by the Treasury.

The two reasons which ought to ensure superannuation are age and ill-health. The amount of it ought to be determined by length of service. Ill-health from any cause except a man's own fault ought to secure superannuation, but that this may be fairly administered it can hardly be questioned that a medical board ought to be constituted in Dublin for the purpose of examination. The question of the age at which superannuation ought to take place is one open to more discussion. In Government offices sixty years of age is the earliest period for retirement if the health is good. But the case of a Government clerk, who can go quietly to his office at ten, and return at four, and who can take tram or cab if the weather is unfavourable, is not comparable to that of a Poor-law medical officer, who must pursue his work in all weathers, and at all hours of the night and day, and who must, in many districts, make great physical exertion in crossing mountains and bogs, where no conveyance can travel. There is an amount of physical exertion demanded of medical men which falls to the lot of none other of the educated classes of the community. They must exercise their muscles after the fashion of farmers, shepherds, and the constabulary. Now a shepherd is pretty much past his work at 55, and is either pensioned by his employer with a free house and a bit of ground, or he has to get relief from the workhouse; the farmer can hand over the heavy work to servants or grown-up sons; and the police-constable is sure to get put on pension at 55. I contend that it is only reasonable that the medical officer should have an opportunity of getting rest too when he reaches that age. While he is in harness he must be at his post; he cannot do his work by deputy. No doubt a substitute will be found for him if he is suffering from severe and prolonged illness, but it is just about the age of 55 that a man begins to suffer from these beginnings of failing health, which are not great enough in themselves to admit of asking for a substitute, and yet, if aggravated by some severe wetting, or by the exposure incurred during some sudden night call, lay the foundation of permanent disease. There need be the less hesitation in conceding this boon, because no man will take advantage of it who feels himself still able for his work: resignation implies the loss of attendance on police and of registration and vaccination fees; his income will therefore certainly be reduced very considerably. Moreover, he of necessity brings a rival to compete with him for any private practice that may be to be had. It may therefore be safely assumed that no one will avail himself of it unless he feels those premonitions of old age which warn him that he is not the man he once was, and that unless he gets some relief from labour his days are numbered.

Reasonable as it appears that superannuation should be equable in its distribution, there is no doubt that any attempt to grant it as a right will meet with the most determined opposition. I believe that one essential condition of success is that every Poor-law medical officer should at once become a member of the Irish Medical Association. I became a member about a year ago from a lively sense of favours I had received through the Association in the shape of increase of salary, &c., my conscience not allowing me to accept of benefits procured by the money and labours of others to which I contributed nothing. But in the present instance there is room for the working of that yet more potent form of gratitude which some one has defined to be a lively sense of favours *to be* received. I would therefore urge, with all the energy in my power, on every medical officer to become a member of the Association.

I am, &c.,

ALEX. W. WALLACE, M.D.

Parsonstown, November, 1879.

NORTH DUBLIN UNION.

LETTER read from Dr. Kirkpatrick, medical officer of the union, regretting that he had to tender his resignation, owing to ill-health, and thanking the guardians for the courtesy and consideration which he had received for a number of years from them.

Mr. Kennedy regretted the resignation of Dr. Kirkpatrick, and alluded to his eminent services, and hoped the guardians would give Dr. Kirkpatrick the highest superannuation in their power (hear, hear).

Alderman Meagher also exceedingly regretted to hear of the resignation of Dr. Kirkpatrick, who had for forty-

Digitized by Google

seven years transacted his duties in a most efficient and admirable manner. He thought the consideration of the resignation should be postponed for five weeks, with a view of allowing them to see what was the largest superannuation they could give (hear, hear). He moved a resolution to this effect, which was unanimously adopted.

LIMERICK UNION.

THE following letter was read :—

SIR,—The L. G. B. for Ireland have had under consideration the proceedings of the Board of Guardians of Limerick Union, on the 15th ultimo, in reference to the reported failure of the medical officers of the workhouse to comply with a code of rules drawn up by the guardians for their guidance ; and in reference to the resolution on the subject, the L. G. B. desired to state that they have framed rules for the guidance of the medical officers of the workhouse, which have been in operation for many years, and have been regarded as sufficiently effective and comprehensive for all practical purposes, and then do not consider it desirable to sanction exceptional rules which would be in application to the majority of workhouses. At the same time, the L. G. B. presume that the medical officers of the Limerick workhouse will comply with a reasonable recommendation of the guardians as to their attendance and the discharge of their duties.—By Order of the Board,

B. BANKS, Sec.

Alderman Phillips asked if some of the officers at present in the house were appointed when the rule referred to by the L. G. B. was made.

Chairman—I do not think so.

Alderman Phillips did not at all know the reason of the L. G. B. acting in such a way. They now say that they have rules of their own which they suggest to the guardians to put in force. These rules were in force before they had resident medical officers. He suggested to have the matter left in the hands of the Hospital Committee.

Lord Clarina concurred.

Mr. J. M'Donnell said it was not the duty of the guardians to interfere with the medical officers in the discharge of their duty.

The guardians adopted the suggestion of Alderman Phillips.

ABBEYLEIX UNION.

VACCINATION DEFAULTERS.

An application was received from the relieving officer for remuneration for his trouble for hunting up defaulters under the Vaccination Act.

The Clerk said the local government had authorised the guardians to give the relieving officers some suitable remuneration for their trouble.

Mr. Owen—Is it not part of the relieving officer's duty to look after this matter? Well, if he allows a number of cases to accumulate in this way, why should we remunerate him for his trouble in looking after them?

The subject dropped.

THE MEDICAL OFFICERS OF HEALTH AND SANITARY PROSECUTIONS.

The following letters were read :—

Durrow, November 17th, 1879.

DEAR SIR,—Yours of the 10th inst. received, with a copy of a resolution passed by the sanitary authority on the 14th ult., viz., "That the salary to be paid each medical officer of health shall include his attendance at petty sessions in sanitary prosecutions."

With great respect I would observe that the terms of this resolution are not in accordance with those of the 258th sec. of the Public Health Act of 1878, which provides that any such arrangement shall be by agreement between the Sanitary Authority and the Medical Officer of Health, and I cannot consent to give my services at sanitary prosecutions without remuneration. I beg respectfully to say that the resolution referred to cannot debar me from claiming the fees to which I am legally entitled under the above-mentioned section.—Yours, &c.

J. R. PALMER.

Castletown, Mountrath, 11th November.

DEAR SIR,—I received your circular, with a copy of a resolution adopted by the board of guardians at its last meeting. I will be obliged by your informing the board that the resolution is in no way binding on me.—Yours truly,

W. HANRAHAN.

The letters excited no discussion.

WE regret to learn that a serious accident has occurred to Dr. Gabriel Stokes, of Mullingar, who, owing to the breaking of the belly-band of his horse, was thrown off his car, and sustained a fracture of the collar-bone. We are glad to learn that he is progressing favourably.

POISONING BY LAUDANUM.

LAST week an inquiry was held at Coagh, in the co. Tyrone, touching the death of a woman named M'Iver, who had come to her death under the following circumstances :—It appeared, from the evidence of a little girl, that the deceased was in the habit of taking laudanum frequently, and that she had sent witness to M'Callen's grocery shop for one halfpennyworth of laudanum. The witness brought a cup with her for the laudanum, and was attended to by Bella M'Callen, the grocer's sister, who poured it into the cup without measuring it. When the little girl returned, deceased drank up all the contents. Witness thought there was a teaspoonful and a half in the cup when she reached it to deceased, who remarked that it was a good halfpennyworth.

Dr. Burges in his evidence animadverted at length on the manner in which laudanum and other poisonous drugs are sold in grocery shops, and remarked that it would be more safe to the public if the sale in such shops of these dangerous drugs were prohibited.

The verdict was as follows :—"That the deceased came to her death by an overdose of laudanum, taken by her on the 21st November, 1879, without any intention of destroying herself—the laudanum being incautiously supplied by a local grocer, and we believe sufficient vigilance was not used in procuring medical aid sooner."

SLIGO UNION.

THE PAYMENT OF MEDICAL OFFICERS' SALARIES.

A CIRCULAR was received from the Mountmellick Guardians forwarding a copy of a resolution passed at their meeting with reference to what they called the "arbitrary" conduct of the Local Government Board in fixing, by sealed order, the salaries of the sanitary officers. They wanted to know what salaries the doctors got under the Sanitary Acts of 1874 and 1878, and if the salaries proposed by the guardians were objected to by the Local Government Board.

The chairman said he saw by the proceedings at a late meeting of the Boyle Board of Guardians that Colonel King-Harman, as chairman of that Board, had an interview with the Local Government Board because that Board refused to sanction a reduction of the salaries of the medical officers of the union.

Mr. O'Brien—Have they got any increase lately?

Chairman—They have a shilling additional for every

Digitized by Google

person vaccinated, and other things. I think we may let it stand for the six months.

Letter marked read.

COLLOONEY DISPENSARY DISTRICT.

The L. G. B. forwarded to the guardians the following extracts from a return furnished by the doctor of the Collooney district, and they requested that the guardians should furnish their observations thereon:—

I believe there are a number of children in the district above six months old not vaccinated. I have done everything I can think of to try and make the parents bring their children to be vaccinated without little success. The number of children vaccinated this year under 6 months old was 5; over 6 months and under 12, 46; 1 year old and under two years, 60; 2 years old and upwards, 23—total, 134. The above figures speak for themselves. I consider the Vaccination Act, so far as this district is concerned, to be a complete farce. A long list of defaulters is sent in twice a year to the guardians. The relieving officer warns the people to comply who have not done so. About half of these come in, and then the matter rests.

The chairman and guardians seemed to think this a serious matter.

The Clerk said that there was a return called "Form P" which the doctor was bound to supply. It would be well to call on him for that, and then they could proceed against the defaulters.

This was ordered to be sent in.

WEXFORD UNION.

A LETTER from the Local Government Board on the proposed reduction of the salaries of the medical officers of health, desiring to express a hope that the guardians will consider the subject again, as the board are unwilling to resort to a sealed order for the purpose of regulating the additional salaries of the medical officers. If the guardians will fix them at the present rate the Local Government Board will consent to their being revised at the end of six months if it should appear meanwhile that the officers do not perform any additional duties under the recent Act and Order.

Captain Hamilton—I would ask you to assent to the terms of that letter, particularly as they offered at the end of six months—in the event of its being shown that no additional duties have been performed—to consider the matter. You are aware that all you are asked to do is to fix the salaries as they were under the Act of 1874. You are not asked to give an increased salary, although the officers of health have additional duties to perform under the Act of 1878. The Local Government Board, under the 11th section of the Act, is made a party to it, and are obliged to comply with it. Mr. Murphy said on the promise contained in the letter, though in justice to themselves he should say £10 was quite sufficient, still he would propose that the salaries remain as they were under the Act of 1874. Adopted.

OMAGH GUARDIANS.—OMAGH DISPENSARY POSTAGES.

THE letter of the hon. sec. of the Dispensary Committee, showing that he had been to the expense of 2s. 1d. in providing postage stamps for circulars summoning a special meeting of the Committee was read. The meeting had been convened on the written requisition of two members of the committee, to consider Dr. Fleming's application to be allowed to continue the services of an assistant doctor.

The Chairman could not see how the Guardians should object to the payment.

Mr. Moore said when the meeting was convened solely for the benefit of the dispensary doctor, he *thought the doctor, and not the Guardians, should pay the account for postage*. Another objection he had to the payment of the item consisted in the fact that the names of the members of the Committee requesting the meeting were not given in the circulars.

Mr. Greer said this was a quarrel about a shilling and a halfpenny (for the Local Government Board would refund half of the whole amount). It was the first time he had ever heard of the secretary of a Dispensary Committee being refused the amount he had spent in the postage of circulars. Dr. Fleming did his duty as well as any doctor in the union. Mr. Moore, in some cases, was not so chary about the rates of the union as he was at present. He moved that the postage account of 2s. 1d. be paid.

Mr. Moore said he believed that this "letting in the thin end of the wedge" would result in an endeavour on the part of some to have two doctors appointed to the Omagh district. Dr. Fleming took the post with his eyes open, and he should be able to do what Dr. Love did for twenty years, without ever applying for an assistant. He proposed that the postage account be not paid, as the meeting had been solely for Dr. Fleming's benefit.

Mr. Clements said he had no vindictive feeling towards Dr. Fleming, yet was inclined to Mr. Moore's view of the matter.

The question was put to the meeting, and payment of the postage account was passed by a large majority.

[It does not seem to have occurred to anyone that the Board of Guardians has no power whatever to refuse payment of such a charge, and if they did refuse, the hon. sec. might "decree" them for the amount on the first opportunity.—ED. M. P.]

REMUNERATION TO RELIEVING OFFICER FOR SERVING VACCINATION NOTICES.

The next special business was the consideration of Mr. Joseph Beattie's motion "That Mr. Cochrane, Relieving Officer, be paid at the rate of £5 per annum for the last four years, for serving notices under the Vaccination Act."

The motion was seconded by Mr. Hugh Gasham.

By a recent resolution of the Board Mr. Cochrane's duties in this respect had ceased, the Guardians ruling that the notice emanating from the doctor should be deemed sufficient, and the motion was for a remuneration of Mr. Cochrane's past services which had not been paid for by the Board.

After a considerable amount of discussion, on the amendment of Mr. A. C. Buchanan, seconded by Mr. Claudius Martin, Mr. Cochrane was awarded the sum of £5.

ACCORDING to the *Apotheker-Zeitung*, of 118 samples of children's toys officially examined in 1878, 53, or nearly one-half, were adorned with poisonous colours. At least 50 per cent. of these German toys are made for the English market.

TO READERS.

THE Editor will feel especially obliged by receiving copies of newspapers which contain any Poor-law or other intelligence of medical interest, in order that he may, if fit, republish it for the benefit of the readers of the *Medical Press*. Although twenty-one of the leading Irish newspapers are received at the Irish office, many things may escape notice which are deserving of attention. Newspapers should be marked, and address to Dr. JACOB, at the Dublin office of this paper.

DIPHTHERIA.

By W. H. DAY, M.D.,

Physician to the Samaritan Hospital for Women and Children.

(*Continued from page 475.*)

Causes.—A specific poison, either generated within the body, or external to it, is the cause of diphtheria, which spreads by contagion and infection. Sir W. Jenner traces "diphtheria (like erysipelas) to cold when the exposed person is depressed from fatigue, mental or moral causes, &c."(*a*) It spares no class of the community, affecting the poor as well as the rich when an epidemic prevails; but it is probable that, notwithstanding the evidence that has been brought forward to the contrary, defective drainage, debility, and exhaustion favour its development. The disease is not peculiar to any particular locality; it has been as prevalent in high and exposed situations as in low and sheltered places; on clay and damp soil, and on dry and light soil; on richly cultivated soil, and on barren moorland; in the open country and in the densest towns.(*b*) It does not, however, appear to be so frequent in dry districts, where the drainage is good and the soil permeable, as in damp marshy districts in the vicinity of water. Still, this does not clear up the cause of the epidemic, for dry places have been severely visited, and damp places have escaped. "Indeed, it is evident that some other factor besides damp is required for the causation of this disease, seeing that humidity in every conceivable form and degree always exists in one place or another; whereas diphtheria had been unknown as an epidemic in this country for three-quarters of a century previous to its recent invasion. Dampness must, therefore, be regarded rather as an auxiliary than as a principal cause of the disease." (*c*)

As to the outbreak in North London, in 1878, Mr. W. H. Power found that, with regard to time, the customers of milk retailers who bought their milk of the same proprietor, possessing a farm at Muswell Hill, as well as cowsheds at Kilburn, bore almost the whole of the brunt of the outburst, which first attracted attention to the district, and which was referred to sewer causation. It seems probable that Mr. Power's observations must be regarded, in the present state of our knowledge, as rather suggestive and incitive than conclusive.

What the exact nature or essence of the disease is we do not at present know. How the germs of the disease are first developed, whether they ever arise *de novo* (which is not improbable), or whether the soil into which they have been introduced is peculiarly adapted for their growth, are questions which the science of medicine has still to deal with, but certain it is that when a person is struck down with the disease, he is capable of contaminating the surrounding air and drinking water, and so of communicating the disorder to others.

Bretonneau held the view that the atmosphere could not transmit the contagion of diphtheria. He taught that the only way in which it can be contracted is by inoculation—that the diphtheritic secretion must come in contact with "a soft or softened mucous membrane or with the skin, on a point denuded of epidermis." (*a*) This is a subject still open to discussion, but most authorities agree that the disease is contagious, and can be conveyed by the atmosphere, invisible emanations from the sick, or even from sewer gas.

Family susceptibility is sometimes very great. All the members of one family may be attacked, whilst those of another family living under the same roof may escape. Some may have the disease slightly, and others severely; the delicate succumb more readily than the strong.

A correspondent throws out the hypothesis that as the disease often spreads in a family, and does not extend to other persons going freely about the patients, "the poison germ of diphtheria is modified by its habitat, becomes, in fact, a new variety growing out of, and specially adapted to, the constitution in which it has developed, and that

this contagion finds in the kindred constitutions of brothers and sisters fit soil for its growth, while it is thrown off by stranger organisms to which it is unadapted." (*a*) Dr. Alfred Carpenter also supposes "that diphtheria is dependent upon a germ of living matter, which is capable of reproducing itself when it meets with a congenial soil." He considers that there is a close analogy between it and potato blight, the conditions which promote the one have also an influence upon the other. He adds that sulphurous acid, locally and generally applied, is the best application, and that the germs cannot grow in a creosote atmosphere. (*b*)

The clothes of a person may be infected with the poison, and he may thus transmit the disease to others, though he is not labouring under it himself.

An instance came under my notice in November, 1878, where a little boy in health called at a house in which a child was lying ill of the disease; he returned home, was struck down with the disease within forty-eight hours, and died on the seventh day. He conveyed it to two brothers and a sister. The little girl, eight years of age, walked eight miles one day, was prostrate with the disease on the next day, and expected to die on the third or fourth day, but eventually recovered.

Sequelæ.—The heart is prone to become enfeebled, notwithstanding the free exhibition of stimulants and the progress towards recovery. Sudden failure of the pulse and circulation now and then comes on, and the weakness continues till death. Valvular disease of the heart has been known to result from diphtheria. The processes involved in this disease may bring about morbid changes of the endocardium affecting the valves. Dr. Burdon Sanderson (*c*) has shown the identity of the valvular lesions after diphtheria with the ulcerative endocarditis of Kirkes, well known to result from several acute specific diseases. Sanderson continues by demonstrating what he happily terms the "doubly infective character" of those forms of endocarditis after acute diseases. They result from specific infection, and in turn produce morbid changes in the organs. Infective material becomes detached from the diseased valves, and distributed to the kidneys, liver, and lungs. (*d*) Heiberg and Weigert go further, and pretend to have discovered the very *fons et origo mali* in colonies of micrococci which they believe produce the endocardial disease.

Sometimes the muscular system is fearfully depressed, and the patient loses all power over his limbs, so that he cannot support himself or put on his clothes. More frequently the muscles of deglutition are seriously involved, and the sensibility of the fauces is so affected that fluids return through the nose, whilst solids cannot be swallowed, and the voice is weak and nasal.

Dr. Greenhow has recorded a most instructive case of diphtherial paralysis (*e*) in a young woman, aged twenty-one, which followed sore-throat said to be diphtheritic; the left side was most affected. There were cough, much expectoration, and loss of voice, so that she could only speak in a whisper. As the throat improved "her voice became snuffling and indistinct, and she had difficulty in swallowing liquids. A few days later she had begun to experience a sense of numbness, and of tingling and pricking, as if of 'pins and needles,' in the tongue, palate, and lips, attended by loss of taste." A month before Dr. Greenhow saw her (June 29, 1869) she lost all these symptoms, and considered herself convalescent, when suddenly, whilst walking a short distance, "she felt a pricking and tingling in the feet and lower limbs, with loss of power, as if her feet and limbs would give way under her." To this succeeded pricking and numbness in the tips of the fingers and wrists, and she did not know when she held an object unless she also saw it. Her sight now became impaired, and it grew so bad that she could only just see to move about the room. On July 2, when admitted into the Middlesex Hospital, among the paralytic symptoms of impaired motion and sensation, she could not tell whether the object she held was hard or soft, hot or cold. The fauces were red, and the left side of the soft palate and the muscles of the left cheek moved less freely than the right. There was a soft systolic blowing murmur at the base of the heart; the urine was free from albumen, but deposited a cloud of phosphates. Under the use of iron, strychnia, and a full diet, with a pint of bitter ale daily, she was discharged convalescent on August the 7th.

ON SHOCK. (*a*)

By E. D. MAPOTHER, M.D. Qu. Univ.,
President of the Royal College of Surgeons, Ireland.

Gentlemen,—In opening the Forty-ninth Session of your Society a difficult duty devolves upon me, that of offering to an assemblage of educated and experienced practitioners any general remarks of interest or value. Addresses in this and similar places have exhausted biographical, historical, and medico-political topics, and I find that already sound practical papers crowd our programme for this and subsequent meetings. I therefore, crave your indulgence whilst detailing some physiological and surgical reflections which have occurred to me. They relate to Shock, its nature, endurance by certain races, and treatment.

That the vaso-motor nervous system is profoundly engaged in shock, such as that from great burns, appears in the weakened heart, contracted arterioles, lowered temperature, and ashy-pale and shrunken skin. Meanwhile, many of the cerebro-spinal functions are unimpaired. Last September, a cook, burned over five-sixths of her surface, was brought to St. Vincent's. Although the body was soon almost that of a corpse, as to pulselessness and coldness, her mind was perfectly clear till within ten minutes of death, which occurred eight hours after the accident. The same may be said of the collapse caused by cholera, or rupture, or gangrene of an abdominal viscus. In 1866, the testamentary capacity of a gentleman, who made his will within half an hour of his death by choleraic collapse, was allowed in the Probate Court on my evidence, and that of others who had attended him.

The cerebro-spinal functions may, therefore, be unconsidered whilst we estimate surgical shock, and it may be taken for granted that the crush of a palsied limb would shock as would the crush of a hardy limb. On the other hand, Sir J. Paget tells us excitable people, with "too great vivacity of the cerebro-spinal system," bear operations well; pain may be loudly complained of, but the circulation is unmoved.

The essential phenomenon of shock, contracted arterioles, can be observed in the rabbit's ear, the bat's wing, or the frog's web, when a remote part of the animal is injured, and it is possible to see the same in man. When strong light is thrown on the mucous surface of the lower lip, everted and steadied in a clamp, the smallest vessels may be watched, no colouring matter intervening, and our expert ophthalmoscopists could readily show us the retinal arterioles in a collapsed patient.

This lessening of calibre could be due to any of four causes—

1st. Lowering of the heart's force, which normally expands the vessels.

2nd. Palsy of the muscle supplied by dilator nerves, which in many parts had been shown to widen by shortening arterioles.

3rd. Spasm of the circular muscles of the vessels themselves.

(*a*) The Inaugural Address read before the Surgical Society of Ireland, Nov. 21st, 1879.

Digitized by Google

4th. The arrest of capillary and tissue interchange, the "*vis a fronte.*"

A few points of evidence for and against each possible factor may be adduced, the unsettled question whether the vaso-motor nerves arise in cerebro-spinal or pre-vertebral ganglia being disregarded.

The pulse falls in every form and degree of collapse, including syncope, which Travers laconically called "an epitome of shock."

When death follows instantaneously great injuries to parts other than the brain and upper fifth of the cord, the heart is plainly the prop of life which has given way. Crushing of a testicle, or of a limb, or blows on the epigastrium without visible lesion, have caused instant reflex palsy of the heart. It is noteworthy that deaths by the last-named violence are infrequent, some six being recorded, and that in two homicidally produced, criminal pathology was at fault, for acquittal followed on the grounds that no cause of death was found on the body.

Slighter contusions over the abdomen will slow the pulse for days. Last month I admitted a lad because his pulse was but 44, who, ten days before, had fallen on the pit of his stomach across a bench. There was no lowering of temperature, nor indeed, any other physical symptom, but he had much dread of ill results. In a few days his pulse settled at 80, probably its normal rate.

Wounds of the heart have been always followed by profound shock even before loss of much blood, and section of the cardiac nerves on one side will slow the beat, while stimulation of the distal segment will quicken it. That shock is reflex would appear from its greater intensity and persistence when nerves are crushed, conduction being still possible, than when they are wholly severed. If in shock the heart were but secondarily affected it could only be by want of blood for its own substance, or the pressure on the semi-lunar valves of blood thrown back from the arterioles. It has been well said that the heart lies within a greater heart—the chest—the movements of which urge the blood most powerfully, and we, therefore, seek other explanations of shock, or to put it practically, we do not place all our trust in alcohol and other cardiac stimulants.

It cannot be doubted that there are nerves which, when artificially excited, cause longitudinal muscle in arterioles to widen by shortening those vessels. So widens by shortening, lengthens by narrowing the bowel and the worm from which the movements are termed vermicular. Such nerves have been most plainly demonstrated in the supply of organs of occasional activity, the sub-maxillary gland, intestine, penis, and ovary, wherein secretion, absorption, erection, and turgescence may be respectively promoted by the greater afflux of blood. It is easily conceivable that shock would palsy dilator nerves, and let the contractors gain mastery. From the pelvic and abdominal viscera proceed the profoundest shock impressions, and in them dilator nerves most abound, and cerebro-spinal nerves are fewest. The latter organs have a peculiar circulation controlling absorption and great tissue change, and on it also shock may specially tell.

Ruptures of the alimentary canal and of the uterus, injection of iodine into ovarian cysts, escape of irritants into the peritoneum, are amongst the causes which have killed by direct shock, or to use the words of Paget, "the shock of suddenly ensuing vast local disease."

If there be such dilator nerves in the limbs they do not accompany the great trunks, for section of the sciatic or brachial plexus causes dilated vessels just as occurs in the head when the cervical sympathetic is severed.

That poisons in the blood stream will excite to contraction the circular muscle of the arterioles has been most ably urged by Dr. G. Johnson, the cholera poison, and some morbid state of blood in asthma, on the pulmonary, and urea on the renal and general vessels being his favourite examples of this state in acute, occasional, and chronic forms. So highly do I estimate the powers of observation and of philosophical argument which that great physician possesses, that I confess myself convinced against my will. I mean that surgical collapse could not be accounted for by primary spasm of any muscle, though that of choleraic collapse might be, and I regret that two such similar states cannot be shown to have similar causes. One vegetable poison, tobacco, was shown in 1837, by James Blake, to kill by obstructing the pulmonary circulation, not by directly weakening the heart. The rigor which tells us a morbid poison has hatched points to difficulty of pulmonary circulation, while at the same time the albumen in the urine tells us the blood is not getting freely through the kidneys.

Vaso-motor spasm is usually symmetrical; for instance, the thermometer has fallen to 32° in one hand, while the other was kept in ice, but the coldness following on a crushed limb has not been specially found in its fellow. The spasms might be reflex, the sensory nerves carrying the impression centred, and in this way the main therapeutic effect, contraction of deeper vessels, produced by blisters, has been accounted for. The intensity of shock caused by extensive burns, especially those exposing the papillæ, supports this idea of reflex spasm.

Sedatives, opium, chloral, and the like, we should use if we saw we had to deal with pure muscular spasm excited by pain.

The rise of temperature after death by choleraic and some cases of surgical collapse could be explained by the relaxation of arterial spasm, tissue oxidation being for a while resumed. The axilla has given 110° fifteen minutes after death by a crush of the cervical cord. In support of the theory that in collapse death is by apnœa, it may be stated that in carriage accidents the danger by shock is in inverse ratio to the amount of air in each victim's lungs, the greater amount drawing forward the blood for aeration the longer.

The gaseous, liquid and solid contents of capillaries pass every instant of our life outwards, and inwards proceed at least gases and liquids. These interchanges resulting in the building of tissues and the removal of their ruins when oxidised, set free the heat which marks the being from the thing. Such is a potent, perhaps universal force in plants and in the humblest animals, although vessels and nerves may be unseen. In shock at once fatal, such changes cease, and molecular quickly follows on somatic death, a necromia or necrobiosis occurring.

Animals are the more easily killed by shock, the higher their temperature—the whaler's harpoon and the fowler's shot quickly kill beings whose calorific power mounts to 110°. When, by want of food, their temperature falls, the slightest injuries prove fatal. The Greeks fed on meat before battle were heroic, and many a poor fellow in our hospitals bears an operation the better for a week's good diet. The hybernated mammal is like a man in shock—food, tissue-change, temperature, breathing, pulse, all lowered, and the restorative for each is the same, heat. Men habitually in air heated up to 120°, and sweating 3 lbs. per hour, such as steamer and gas stokers, fall from slight chills into collapse approaching that of cholera.

Nerves may exist in the humblest animals, although from transparency and minuteness our microscopes do not show them, and capillaries may have muscles and nerves controlling them. Indeed, Stricker has, in young tadpoles, contracted capillaries by electricity. It is, however, probable, that in shock the veins throw back blood to the capillaries, and that therein it may clot and stop tissue change. The blood cells are mainly formed in the abdominal organs, and the membrane which envelopes them, and the vast shock following injuries of these parts may be explained under the head we are now discussing. People with slow circulation and cold extremities bear shocks ill, but other surgical processes favourably.

Here I may note that temperature is the main guide in the diagnosis and prognosis of obscure internal injuries attended with shock. In a large series of observations in St. Thomas's, Mr. Wagstaffe found the mean fall of the thermometer in injuries of the brain and cord to be 5·8°, and in peritoneal injuries 4°. Among great falls, in

Digitized by Google

fatal cases, may be noted ovariotomy, just after operation, 90°, fatal in 12 hours; fractured skull, 87·4°, fatal in 9 hours; fracture at 6th cervical spine, 81·7°, fatal in 48 hours. In spine cases the coldness is always proportional to the height of the lesion of the cord. The lowest temperature ever recorded where recovery ensued, 91·2°, was a case of cut-throat, mental depression having probably much to do with that result.

The violence of shock in infants is due to the great inhibitory power of the sympathetic; the heart and tissue change are active, yet calorific power is low. Pain is, in them, probably the excitant of the shock, and with no patients are anæsthetics greater blessings. However, very slight operations on children will shock fatally. Thus died, in 34 hours, a boy, æt. 3, whom I circumcised in St. Vincent's, in 1860.

The intense shock from injuries to the skin may be due to the extent of its sentient surface, or to the arrest of its blood-making and blood-aerating functions in the lymphatics and capillaries. If the blood be arrested near the surface radiation and evaporation will quickly rob heat. On the whole, although I prefer the palpable to the occult, I think that the extinction of the *vis a fronte* best explains the phenomena of shock.

I remember being much struck on reading the remark of Velpeau when the greater mortality of the operations in French than in English hospitals was being debated in the Academy. He exclaimed, "I admit a sort of immunity in favour of the English flesh which, by a kind of physiological privilege, proves more refractory than French flesh to the accidents which ensue on great operations."

A few words, therefore, as to the physiological characters of the races which most concern us. Of the points Tacitus assigned to the Saxon, "Cœrulei oculi, rutilæ comæ, magna corpora," the last most endures—plentiful animal food having kept up visceral strength. Captain Ross chose for Arctic voyagers those sailors whom he knew to be great eaters. Saxons, cradled in an Asiatic climate where the summer is for two months only, and made hardy in the north of Europe, bear residential changes best of all men.

The pure Celtic Irish showed Aryan origin more plainly, as Strabo calls them poephagi—vegetable feeders. He and subsequent writers, friendly and hostile, point to their cerebro-spinal activity—shown by muscularity and mental endowments, but also to their want of self-reliance, causing them to follow and expect much from leaders, self-elected and self-serving. At no time more fitly than the present may it be said that history repeats itself.

The vaso-motor and visceral strength of the Celts have, during many centuries, fallen with scanty food, and their weak endurance of climatic changes raises the death-rate of New York and other ports where emigrants arrive. It is certainly hard to tell the proportion of Saxon to Celt in Ireland. In 1760 it was said to be in Connaught 1-10th, in Munster 1-6th, in Leinster 1-3rd, and in Ulster 3-5ths; but now the proportions are much less. As Saxon immigrants have been in greatest proportion males, the visceral characteristics of the Celtic mothers have prevailed in their descendants. Dr. Beddoe found out of 1,300 Dubliners, 54 per cent. had fair hair, and Wilde, of 1,200 other Irish, discovered the iris to be per cent. blue in 24, brown in 9, and dark in 66.

Thus far had I written when I sought for statistics of the relative shock-endurance of the Saxon and the Celt. Time only allowed me to search as to the first in the London hospitals' reports, and I carried away the impression that after great injuries and capital operations, the deaths by secondary causes, uræmia, septicæmia, sloughing, lung complications, and exhaustion, are greater than ours, but that deaths by shock are proportionally vastly less.

Take ovariotomy, shock does not cause half the deaths in London, as in Dublin, judging of our city by Mr. O'Grady's reliable statistics. I feel bound to say that the principles and practices which should guide us in this and other great operations are not systematised with us city. Our hospitals are numerous, but small—one-sixth the average London size—hence large data can be only collected by their being formulated for all in common. This Society appears to me capable of affording such organisation—the more so as its secretaries never seem tired of work.

Although ovariotomy in Germany has a high mortality, shock is a rarely assigned cause. Mr. Wells last week stated that, since he began thorough antiseptic practice he had 6 deaths in 81 cases, the last 36 operations having all survived. The latest example of Saxon endurance of shock was that of 35 German cases of Battey's operation, not one killed by shock; the 9 deaths were by septicæmia.

The French statistics of ovariotomy show a very high mortality by shock, and in the Crimean and Franco-Prussian campaigns, gunshot wounds and operations on that side were far more fatal than on the sides of the Saxon nations—English and German. For example, MacCormac tells us that among the French, after Sedan, 19 of 27 gunshot fractures of the thigh were fatal; while Stromeyer reported from the German side only 6 deaths in 34 like cases.

A French soldier frets unceasingly if a ball remains in, or if he bears a shattered limb, hence the pressing need for primary operations. Malgaigne allowed that the mortality in Paris hospitals after thigh amputations was 62 per cent., while at the same time, according to Sir J. Simpson, it was in British hospitals only 38. The Saxon's calm endurance, and the Celt's over-sensitive and excitable temperament, go far to explain these striking differences.

No disease ever differentiated race so remarkably as the sweating sickness in Ireland in 1492—the English being exclusively attacked, owing probably to their grosser food.

Sir J. Simpson assures us the potato-fed Irish, the oat-fed Scotch, the rice-fed Hindoo bear operations wonderfully; but this I am sure is because secondary evils more rarely come on, not that their shock endurance is greater. The often-quoted constitution of the brewery workman is just the antithesis.

The East Indian tribes are usually believed to bear injuries and operations with wonderful immunity; but I think this refers to their not suffering such secondary ills as sloughing, pyæmia, and the like, and their freedom from visceral disease, because of temperance in food and abstinence from alcohol. Such operations as herniotomy, and such diseases as cholera, great producers of shock, kill them more easily and rapidly than European residents. Much the same is true of the American Indian tribes, who spread from them along Behring's Straits, notwithstanding Humboldt's belief in the Irish and Welsh traditions which assign these Celts as the immigrants to America before Columbus. One tribe of them, the Mandans, was blotted out for ever in a few days by small-pox often in its incubative stage.

The black races, African and Australasian, are wonderfully insusceptible of pain, and it was often recorded in pre-anæsthetic times that negroes held the upper part of their limbs while the lower parts were being amputated. The venous system and right heart in this race is greatly in excess; the lungs small. We may thus physiologically account for the above described *sang froid*. In the same races ovariotomy has had slight fatality, and parturition causes little shock, and very few hours' confinement; while negro blood boils up with small-pox, the poisons of yellow fever and ague almost fail to disturb it.

Now a very few final words as to what we can do for those with a great shock. Spasmodic contraction of the minute arteries is certainly the condition, and external heat most certainly relaxes such spasm. No means can equal a hot-air bath; the temperature can be graduated in two or three chambers; complete recumbency can aid the weakened heart's force, and air heated and vapoured to any degree can be inspired. I never saw a man who could more truly have been said to have been revivified than was a bronchitis patient in St. Vincent's,

Digitized by Google

just admitted last Friday night. From one of my surgical wards, I was called to see him dying, as it was believed, in a sudden fit of dyspnœa. Breathing the hottest possible steam, within half-an-hour his respirations became easy, and all traces of non-aeration vanished. How much of the effects of smokes of all kinds in asthma may be due to temperature and moisture. In no other bath than that of hot-air will the sweat forcibly spring from its glands and burst off the coating which covers our unwashed poor almost as continuously and impermeably as the serpent's slough, and if lung aeration be hindered the skin is the great auxiliary. Water baths, or clothing which only retains heat already set free, and in many shock cases scarcely any is set free, cannot act in the above ways. Frictions with turpentine and other rubefacients, and enemata of water at 120°, or of stimulating mixtures, can be readily used in the heated chamber. The drug I have just mentioned seems most suitable for combating shock; it is quickly diffusible and diuretic. Now if morbid poisons will contract the general, pulmonary, and renal arterioles, as rigor, dyspnœa, scanty and albuminous urine seem to show, turpentine must be useful by promoting the passage of the blood through the kidneys. In hysteria vaso-motor irritation there is and turpentine often allays it by diuresis. Nitre by its diuretic, oxygenating, and fibrin-dissolving actions may be also useful.

Expansion of the chest by Sylvester's, the best mode, can be most advantageously used in a hot-air bath, as the inspired amount will give, not rob heat. In shock the blood urged from the surface congests the viscera, and artificial respiration must therefore give relief in the renewal of the fit distribution of the blood. We should remember that the whole of the blood would scarcely half distend all the vessels at once, and it is therefore that arterial muscularity, the great distributor, is so powerful, so vital. In the interest of the shocked, the shivering and the starving, I think there should be in every hospital, near the entrance, a hot-air bath. Its use in many forms of disease is becoming more widely known. The fulness of the right heart, and of the unvalved veins above it in man and other animals under shock and dyspnœa, has tempted Mr. Savory to advise jugular venesection in severe—apparently hopeless—cases. The milder expedient of leeching over the mastoids will as directly, if not as rapidly, drain this dammed back blood.

ON SCLEROTOMY IN GLAUCOMA. (a)

By H. R. SWANZY, M.B., F.R.C.S.I.,

Professor of Ophthalmic and Aural Surgery, Royal College of Surgeons in Ireland; Ophthalmic Surgeon, Dr. Steevens' Hospital; Surgeon to the National Eye and Ear Infirmary.

You are aware that twenty-two years ago the cure for the disease called Glaucoma was discovered by my lamented master, Albrecht von Graefe. Until then this disease was absolutely incurable, and if Von Graefe had not contributed in any other way to the progress of ophthalmology, this discovery alone would have immortalized his name. By means of it hundreds, nay thousands, are annually relieved of a disease which otherwise leads with certainty to complete blindness, attended in many cases with violent and protracted pain. You also know that the cure which Von Graefe discovered for glaucoma is iridectomy. An incision is made in the corneo-sclerotic margin, opening the anterior chamber; through this incision a small portion of the iris is drawn out and abscised. The prominent symptom in glaucoma is increased tension or hardness of the eyeball, due to its being over-full; and this it is which causes the blindness and pain by pressure upon the optic nerve and ciliary nerves respectively. After a properly-performed iridectomy the tension of the globe is permanently reduced to the normal standard in a large number of cases, the pain relieved, and the sight preserved. What causes glaucoma? How does increased tension of the eyeball arise? How does iridectomy cure this disease? To these questions the great author of the cure himself failed to find satisfactory answers. Besides him many physiologists and ophthalmologists have endeavoured to solve these problems, but it is only within the last two or three years that the true light seems to be breaking through the cloud. It does not come within the scope of this paper to give even a cursory view of the various doctrines of glaucoma which have been held from time to time. I shall merely mention that these theories followed in one or other of two chief lines, one which regarded glaucoma as a disease caused by hypersecretion of the intra-ocular fluids, the other which regarded it as caused by retention of those fluids, or obstruction to their passage out of the eyeball. Evidence has of late been running very strongly in favour of the latter view. Now, amongst those who long ago declared themselves as supporters of the theory of retention was De Wecker, of Paris, and not only did he support this view, but he also declared that in his opinion the iridectomy acted in the cure of glaucoma, not by virtue of the bit of iris excised, but by virtue of the cicatrix in the corneo-sclerotic margin. The microscope shows that this wound does not heal by the immediate approximation of its lips, but that a semi-transparent substance is interposed. De Wecker believed that this substance admitted of a freer transudation of the intra-ocular fluids, and thus the cure. Since De Wecker put forward this view, which for many years he defended single-handed, my friend, Prof. Theodore Leber, of Göttingen, has made his famous investigations with regard to the "Interchange of Fluids in the Eyeball." By these he has shown that the point at which the effete intra-ocular fluids chiefly escape is at the angle of the anterior chamber, passing outwards through the ligamentum pectinatum, or space of Fontana into the canal of Schlemm. Pathological researches (Adolf Weber, Knies, &c.) of a still later date have shown that in glaucoma this way of exit becomes obstructed by the adhesion of the periphery of the iris to the periphery of the cornea. These investigations combined now to make De Wecker's theory of the action of the corneo-sclerotic cicatrix seem very plausible, and it remained only for him to establish his position by an operation which would enable him to produce this cicatrix without an iridectomy. The great difficulty to be contended with was the tendency of the iris to prolapse and become incarcerated in the incision, a circumstance which would of course completely nullify the desired effect. Fortunately eserine, the active principle of the Calabar bean, was isolated just at the time, and is now an article of commerce. A drop or two of a 1 per cent. solution of eserine produces an active contraction of the pupil, so that when the incison in the corneo-sclerotic margin is completed no prolapse of the iris takes place. In order the more completely to guard against this occurrence, De Wecker performs the operation which he calls sclerotomy in the following way: With Von Graefe's cataract knife a flap of from three to four millimetres high is formed in the upper portion of the corneo-sclerotic margin, the line of incision lying one millimetre distant from the clear cornea. The flap, however, is not completed, but about one-third of it is allowed to remain undivided, and the knife is then slowly and carefully removed from the eye. During the performance of the operation the aqueous humour escapes, but, thanks to the violent contraction of the pupil from the eserine previously instilled, and to the bridge left standing, prolapse of the iris does not take place. In a paper by Dr. de Wecker, read in the Ophthalmological Section of the late meeting of the British Medical Association at Cork, he reports that he had performed forty-eight sclerotomies, all with good result, since the commencement of the year. The cases upon which he had operated were all cases of simple chronic glaucoma. This is the most insidious form of the disease. Exteriorly the eyes seem, for the most part, quite healthy, there are no so-called inflammatory symptoms, no

(a) Read before the Surgical Society of Ireland. The discussion will be found at page 501.

Digitized by Google

pain or injection of the eyeball. The chief—indeed, I may say the only—objective symptom is gradually progressive blindness. Upon examination, the surgeon finds increased intra-ocular tension, a deeply excavated optic disc, diminished central vision, and contraction of the field of vision. Now in this form of the disease iridectomy has not proved so successful as in the more acute or inflammatory forms, and of this Von Graefe himself was well aware. While many cases of simple chronic glaucoma are arrested in their progress by iridectomy, still there is a considerable percentage of cases in which beyond doubt the downward progress is even more rapid after the operation than before it.

These are some of the most anxious cases with which the ophthalmic surgeon has to deal. The very worst cases of simple chronic glaucoma are those in which the contraction of the field of vision approaches very close to the fixation point, while perhaps the power of central vision may be fairly normal. Let such a case alone, and the central vision will ere long become involved, and absolute blindness rapidly ensue, whilst if an iridectomy be performed the prognosis still is doubtful, and great is the disappointment if soon after the operation the vision deteriorates at a more rapid rate than before. My experience with iridectomy in such cases would make me very satisfied if I succeeded in securing for the patients the poor bit of sight they may have prior to the iridectomy—for an improvement in it I have never looked.

In June last I performed an iridectomy upon a case of this kind in the National Eye and Ear Infirmary. Vision gradually and steadily deteriorated after the iridectomy, although the tension of the eyeball had become normal, and I greatly fear by this time the eye will have become completely blind. At the same time I admitted a patient from North Wales, in whose right eye the sight was completely lost from glaucoma, while, in the left eye, there was simple chronic glaucoma, but the vision was still such that he could count fingers at three feet distance. The patient could not speak nor understand English, so that his examination gave great difficulty, but as well as could be made out the contraction of his field of vision approached very close to the fixation point. The case, then, was very similar to the first one I mentioned. On the 10th June I performed sclerotomy on this eye; on the day after the tension was normal. On the 16th he could count fingers at five feet, and on the 21st at fourteen feet. His vision was probably even more than this, but as he could not spell I was unable to gauge it better. He was evidently very much elated with the improvement in his vision. He returned to Wales, and I have not seen him nor heard of him since. Shortly afterwards I admitted a poor woman from Kingstown whose left eye was almost stone-blind from glaucoma. Her right eye was affected with simple chronic glaucoma, and fingers could be counted with it at twelve feet. The contraction of the field of vision approached close to the point of fixation on all sides, leaving a very small central field free. The stroma of the iris was somewhat indistinct, showing some degeneration of its tissue, and eserine did not produce as active a contraction of the pupil as I would have wished. The periphery of the iris prolapsed somewhat into the wound, but I deposed it with a spatula. After healing a little distortion of the pupil showed that a slight amount of incarceration of the periphery of the iris in a limited part of the scar had taken place. Nevertheless, the reduction in the intra-ocular tension was quite satisfactory, and vision improved to 14-ll. I had this patient at the Infirmary a few days ago for the purpose of examining the operated eye, and found that its condition was in all respects as satisfactory as when she returned home five months ago.

The next case of simple chronic glaucoma with which I had to deal was that of a cabbage-garden proprietor on the north side of the city. When he consulted me, he had nearly lost the sight of his left eye, being able to count fingers with it at three feet only, while its field of vision was greatly contracted. Of the sight of the right eye he had only lately begun to complain, and it amounted at the consultation to 20-lxxx of the normal degree, while there was no contraction of the field of vision. In each eye the intra-ocular tension was considerably increased (T + 2). On the 30th September I performed sclerotomy on the worst eye with the object of observing its effect before applying it to the other and more valuable organ. The result was most satisfactory, the tension being reduced to the normal, while the vision continued as good as before the operation. One circumstance in connection with this eye is to be noted, namely, that about a week after the sclerotomy a slight iritis showed itself. I do not in the least refer this to the operative proceeding, but rather to the fact that I continued the instillation of eserine too long after the operation. Notwithstanding the iritis, the result of the operation continued good. I then performed the operation on his better eye with even a more satisfactory result, inasmuch as a manifest improvement in the vision took place, namely, from 20-lxx to 20-l. I have seen this man within the last ten days, and found his eyes in the same satisfactory state. On 26th September I was consulted by a very well-known and most respected practitioner in one of our suburbs. He came to me with one eye completely blind from an attack of acute glaucoma which had occurred some months previously. I found the sight of his right eye in a very precarious state, owing to simple chronic glaucoma. Its central vision was unusually acute, amounting to 20-xxx, and he could read small print. But there was a complete defect in the field of vision to the inside and below approaching close to the fixation point, there was a deep glaucomatous excavation of the optic nerve, and the tension of the eyeball was greatly increased (T + 2). On the 6th October I performed sclerotomy on this eye. It was the most difficult of these operations which I have performed, owing to a very shallow anterior chamber. The result, however, has been most satisfactory, for the vision is now as good as it was before the operation, while the tension of the eyeball is quite normal; and I have, therefore, every hope that this gentleman will continue to enjoy his practice, and be a useful member of the profession for many years to come. No change in the defect of the field of vision has taken place.

Thus the whole number of the sclerotomies which I have as yet performed has been five. This may seem to be a very small number, but chronic simple glaucoma is not a very common disease. So far as it is possible to judge, all these operations have been successful. Of course the great question is, will the effect which has lasted some months or weeks continue for years? and the answer can only be given after years. As yet I have not employed sclerotomy for any more acute forms of glaucoma, not but that it would in all likelihood be as useful there as in the chronic simple form, but because iridectomy is a most admirable remedy for the acute form, and it is not good to forsake an old ally who has always been faithful, and also because the anterior chamber in cases of acute glaucoma is often very shallow, and would make sclerotomy impossible. I do not think sclerotomy is an easy operation to perform accurately; it is without doubt a much more difficult one than iridectomy. It is well, therefore, that each one who ventures an opinion upon it should make sure that he performs it rightly. From the descriptions I have read I have no doubt but that some operators have done the proceeding scant justice in this particular. One surgeon habitually passes his knife through the iris and ciliary body; others find it almost impossible to avoid extensive prolapse of the iris. Every case of chronic glaucoma is not suited to the operation. I would not, so far as I can see, perform it in any case in which eserine did not act well upon the pupil. In none of my cases was there any inflammatory reaction after the operation, nor any irritation of the eyeball. A slight vascular injection in the neighbourhood of the wound was the most that was ever present.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

Session 1879-80.—Opening Meeting.

The opening meeting of the Surgical Society of Ireland for the session of 1879-80 was held on Friday evening, Nov. 21st, in the Albert Hall, Royal College of Surgeons, Dr. Mapother, President of the College, in the chair.

Mr. B. Wills Richardson, Hon. Sec., having read the minutes of the previous meeting, which were signed,

Dr. Mapother then delivered the

INAUGURAL ADDRESS,

which will be found at page 496.

Mr. H. P. Swanzy on

SCLEROTOMY IN GLAUCOMA,

which will be found at page 499.

Mr. Storey.—When I heard that Mr. Swanzy was to read this paper I looked over the statistics of St. Mark's for the last two years. For nearly three years past we have been doing sclerotomy generally in cases of glaucoma. I find only two cases of iridectomy, while there are eleven of sclerotomy. From April 1877 to April 1879 there have been in the house thirteen in the first and twelve in the second year with glaucoma. I had not time to examine the cases sufficiently minutely to separate them into acute and chronic. In the case of those patients sclerotomy has been performed eleven times, the result entered being four times "improved," but the cases are not selected—the chronic separated from the acute. Of these four the record in the case of one is "temporary improvement." In another of those cases in which improvement was recorded iridectomy had to be performed about a fortnight afterwards, the symptoms occurring in all their seriousness. This was a case of chronic glaucoma. There was limitation of the field of vision with very slight exacerbations. The third case was one of absolute glaucoma, in which vision was entirely absent, and the patient was merely relieved from pain. In my own experience I have performed sclerotomy seven times altogether, and only in two instances has there been improvement. In one of those cases I subsequently performed iridectomy, and in the other Mr. Swanzy performed it. The patient left the hospital better. I asked the patient to come back as soon as he could. He came back after three months with iridectomy performed, but it was only after a long time with my friend Dr. Fitzgerald going through the books at the Eye and Ear Infirmary I arrived at the truth—that he had had iridectomy performed. In all the cases in which I did it the pupil acted, and there was never any inflammation after it, or prolapse of the iris, or trouble at all. The operation in some cases was difficult, in others not so difficult. I have a patient on whom I intended to perform iridectomy, but I delayed it, and, after hearing Mr. Swanzy's paper I feel more inclined to perform sclerotomy.

Mr. Fitzgerald.—The cases referred to by Mr. Storey lose a good deal of interest from its not having been reported as to whether they were acute or chronic. Mr. Swanzy's paper referred entirely to simple chronic glaucoma, and it is for that that those who are in favour of sclerotomy maintain that it should alone be performed. My own experience of it is very small. Certainly it is over a year ago since I performed the operation in the case of a patient that was admitted into the National Eye and Ear Infirmary. This was a typical case of simple chronic glaucoma. In one eye the vision was *nil*; in the other perceptibly impaired. Both eyes were stony hard. I first of all performed sclerotomy in the eye in which the vision was lost. I found it had the very good effect of bringing down the tension. On the following day there was some slight perception of motion of the hand. I then performed sclerotomy of the other eye, and although not attended with any marked improvement in the vision up to this date—at least, a short time ago—I found the vision was still holding its own. That, I think, is a very satisfactory result. I have had a somewhat similar one with iridectomy in a case of simple chronic glaucoma in which the defection was kept up, though with slight defection. One of the great advantages sclerotomy has over iridectomy is that from the nature of the wound there is not such danger after the operation, of accidents, such as rupture of the wound. In the case that I have just mentioned the patient was a fidgetty old gentleman, who would not leave his eye alone after the operation, and who managed to run his finger into it in about two days. The result was that he burst open the wound and produced hæmorrhage into the anterior chamber. That subsided after a few days, and he kept his vision tolerably well. I do not think that accident would have happened had the operation been sclerotomy; and we have this advantage in sclerotomy—that if it fails we have iridectomy to fall back upon.

Dr. Jacob.—I am not able to contribute much to the statistical facts laid before you in reference to this operation. I have operated four times by this method within about five months. The first operation was an acute case, the result being entirely unsatisfactory. At the end of ten days I was compelled to iridectomise, the result of the iridectomy, I am bound to say, being equally unsatisfactory. At to the other three cases, I cannot derive from them any conclusion, either *pro* or *con*, in the matter. In two of these there was an undoubted remission of tension and some slight improvement in vision; so much so that I did not feel it necessary to proceed to the reserve procedure of iridectomy to which Mr. Fitzgerald has alluded; and I concur with him that assuming there is nothing better to be said for this operation than that it is at least a tentative measure, we have always a reserve to fall back upon; but I cannot say that from my reading of the subject, or from the observations which have fallen from the speakers to-night, I derive much encouragement to adopt it as a substitute for iridectomy. I would call the attention of the Society to the fact that the adoption of sclerotomy as the procedure of the future is something equivalent to an abandonment of the theory of iridectomy upon which we have up to a few years ago proceeded. Twenty or twenty-five years ago anybody who doubted that the iris was a secreting membrane, that it filled up the eyeball with fluid, and that the removal of a certain portion of its area was an immediate step towards remedying the difficulty, would be considered to know nothing about his business; he would be regarded as utterly heretical. From that time there has been a gradual decadence in the belief of the theories of iridectomy which existed, and we have fallen back upon the theory involved in sclerotomy, that the secreting function of the iris is a myth. I myself think, from a good deal of reading on the subject, that the merit of sclerotomy and a good iridectomy is a good paracentesis. Practically there is nothing gained by one or the other operation than that. I may be heterodox in expressing such an opinion; but bearing in mind the results of a large number of operations I have seen and done, I can arrive at no other conclusion; and that is the conclusion that De Wecker, who has recently written on the subject, indicates. His book on therapeutics was in my hand when I took up the notification for this evening's meeting, and on reading his observations on sclerotomy they appear to me to tend to the belief on his part that whatever procedure may produce a good paracentesis that procedure is theonly known successful procedure at the present time. However there is no doubt the results he gives in his book, and those Mr. Swanzy laid before the Society now, are to a certain extent encouraging; and inasmuch as we are only too happy to adopt any operation which will relieve us from the uncertainties of iridectomy in glaucoma, I think every ophthalmic surgeon will be glad to give sclerotomy a fair trial, and especially glad, considering it has produced such good results in Mr. Swanzy's hands, respecting whose cases in their detail there can be no question.

Mr. Arthur Benson said when at Moorfields Hospital two years ago the operation was frequently performed; but when he was there last year the resident surgeon told him they had completely given it up, its results being only temporary.

Mr. Swanzy, in reply, said.—The chief point which I wished to bring before the Society was the fact that in sclerotomy we had, as it seems to me, a much better remedy for chronic simple glaucoma than in iridectomy; and, as I said, I think it is very probable we might find it useful in acute glaucoma; but inasmuch as iridectomy is such a capital remedy for it, and as it seldom forsakes us, it would be wrong to apply any other. However, for chronic simple glaucoma it certainly seems to me another remedy was very much wanted. We are supplied with it now. I am glad Mr. Storey is going to perform the operation to-morrow with greater confidence than he would have done if he had not come here. Dr. Jacob thinks it is an operation that might be called a paracentesis. After all I think there is no great objection to call it paracentesis; but by that word we mean something with re-

Digitized by Google

spect to the eye which has only a temporary effect. We use it very frequently, but it is employed through the cornea, and in this operation the great point is that the incision should lie in the corneo-sclerotic margin, *i.e.*, where the fluids escape out from the eyeball, and where we want to make a way for them artificially to escape whence they are pent up. With regard to what fell from Mr. Benson, and what they do in London, I am not acquainted with the practice there; but I know that one very distinguished ophthalmic surgeon, Mr. Bowman, sent a communication to the Amsterdam meeting lately in which he very decidedly gave his opinion in favour of sclerotomy; but whether it was only in those cases of chronic glaucoma, or he applies it to others also, I am unable to say.

PROFESSIONAL MENTAL EPIDEMICS.

THE report of the proceedings of the Surgical Society of Ireland, which we publish to-day, affords us an opportunity of warning medical men, and especially ophthalmologists, against the influence of mental epidemics. The communication of Mr. Swanzy on "Sclerotomy," taken together with the opinions expressed by De Wecker in his recent book on "Ophthalmic Therapeutics," and the consensus of speakers at the Surgical Society and elsewhere, may be accepted as a public recantation of the iridectomy craze, and a distinct abandonment of the theory and the neck-or-nothing practice of that operation, which were, so to speak, forced down the throat of British ophthalmologists fifteen years ago. Based upon a theory which was always improvable, and which now appears to have been simply an imaginative effort to give a reason for a pet operation, iridectomy came to be a perfect craze with the fashionable school of eye-surgeons. It was advocated as the heaven-sent inspiration of an ophthalmological prophet—the certain panacea for all diseases which, according to the notions of the ophthalmologist, might, under any conceivable circumstances, tend towards the development of glaucoma. It was not enough to object that there was no physiological ground for iris excision,—we were told that the stupendous curative results rendered physiological grounds unnecessary. There was no use in objecting that no sign of glaucoma yet existed,—we were met with the assertion that, if it did not, it might probably arise, and that to prevent such a contingency iridectomy was indispensable. It was futile to suggest that the eye was hopeless, and the operation could do no good,—we were reminded that it could do no harm, and that blindness was certain without it. Every eye-surgeon who proved stubborn of belief, and who did not swim with the current, was pooh-poohed by the juvenile Sir Oracles of the ophthalmic epoch—the seniors being sneered at as conservative and musty—the juniors as behind the time, and unread in the class of literature which, in the opinion of the new school, was the only ophthalmological publication worthy of notice. In the exacerbation of the iridectomy mania, we have seen irides cut up for old opacities of cornea, for acute attacks of iritis, for myopia, for phlyctenular conjunctivitis, for nerve, brain, and spine diseases of all sorts, and, we suppose by mistake, for trichiasis. In truth, the operation was a real boon to ophthalmologists, was easily done, did not usually do obvious harm, was paid for at about the same rate as cataract extractions or other serious eye operations, and, lastly, served a good purpose by enabling the surgeon to frighten the patient out of his wits with the phantom of a glaucoma, and then to calm his fears, and acquire a good fee and a valuable accession of *kudos* by the aid of the all-curing operation. What have we come to now? The admission that there is no special advantage at all in excision of the iris; that a simple incision at the sclero-corneal juncture is all that is necessary, and that iridectomy is useful only as involving this method of sclero-corneal tapping of the eyeball.

A less cogent illustration of the mental epidemic was the craze for the modified linear cataract extraction now dying out. The access of this form of delirium was nearly contemporaneous with the declaration of the iridectomy epidemic, and the operation may possibly have gained some of its popularity from the fact that it involved the gratification of clipping an iris. Whether this be so or not, the operation was actually made the first article of belief of the so-called "progressive" ophthalmologist. We were commanded to believe that the sclero-corneal incision was the only incision—that a small peripheric cut obviated, and an iridectomy obviated all dangers of extraction—that delivery of the lens was speedy, easy, and complete;—that we might operate on lenses, ripe or unripe, and that we might reasonably expect from 85 to 94 per cent. of success. (?)

How is it now? We know that the small incision is abandoned, and that the semi-peripheric is substituted—that the sclero-corneal position is given up, and (by Liebreich, De Wecker, and other equally eminent authorities) the incision taken between the pupillary axis and the

Digitized by Google

corneal edge;—that the iridectomy is no longer a *sine qua non*, and that lenses can be effectually delivered without it, and better results obtained than with it. This is the reaction in the opinions and in the practice of ophthalmologists!

There is nothing surprising in a change of surgical opinion wrought by experience, nor in the disposition of practitioners who seek after novelties to accept without doubting the over-strained assertions and statistics of ophthalmological inventors. Therefore our comparison of the past and the present of these two operations has little point, except so far as it affords an illustration of the danger of hobby-riding where patients are concerned, and the impropriety of condemning as impracticable and illiterate those who are only cautious in their beliefs and conscientious in their practice. It is easily comprehensible that inexperienced surgeons should seek the credit of being new lights of a new school when they come to see that it takes time to earn a position as new lights of the practical school of experience. We hope, nevertheless, that the rise and fall of iridectomy and the modified linear operation may be useful as an illustrative warning that all is not necessarily true which is new—that novel theories and operations in surgery are nothing the worse for being filtered through a stratum of practical experience, that those who like to see for themselves the facts and the proofs before they adopt new suggestions are not the worse, but the better, surgeons on that account, and, finally, that earnest contributors to our art may be victims of transient mental epidemics which are curable by time.

THE METHODS OF MEDICAL EDUCATION.

The objections which might be raised to the existing methods of medical education may be epitomised in the statement that there is *no* method in medical education, and it will, we think, upon consideration of the facts, be admitted that such an assertion is substantially true.

If we were to take the regulations of the majority of licensing bodies (which are, fortunately for the public, modified by the good sense of teachers and students) as the embodiment of the existing medico-educational system, the method of such education might be arranged in five stages.

1. To receive as student in medicine a boy of undefined age whose mind is a blank in reference to the elementary principles upon which medicine and surgery are built.

2. To leave him to his own devices for two or three years.

3. At the end of that period to demand from him proof that he has paid a large sum of money for fees, and to ask him questions for the purpose of ascertaining that he is master of the whole science and mystery of medicine and all its collateral sciences, saving their practical application.

4. At the end of a few additional months to accredit him as a skilled physician and surgeon upon his giving proof that he has paid another large sum for fees, and upon being satisfied that he has heard and read of sundry manipulative procedures usually adopted for the treatment of the sick.

5. Finally, to exchange with him for a further sum of money, a parchment document to the effect that he is an emporium of experience, enlightenment, and skill, and perfectly capable of treating all diseases.

If this be not in all cases a *précis* of the student's education, it is not that qualifying bodies have enforced any other system, but that the aspirations of the student and the zeal of his teachers have given to his studies in most instances a degree of reality which is more or less voluntary, and which in frequent cases is entirely absent.

If students attend with diligence their hospital practice and their lecture instruction—if they devote themselves systematically and perseveringly to the first years of their course of study, it is not that they would find any insuperable difficulty in "getting up" their business within the walls of a "grind room," and in the last six months of their third year of study, and acquiring without sacrificing their daily amusements, a sufficient acquaintance with the subjects of their examination to pass successively through that ordeal.

It must be confessed that though this statement may not apply to the examinations or the regulations of all qualifying bodies, it is true of the medico-educational system as a whole, for it is notorious that students do frequently pass the scrutiny of qualifying examinations whose personal circumstances render it physically impossible that they should either have fulfilled the "diligent" attendances set forth in their certificates, or studied their profession practically to any extent worthy of regard. In Ireland at least we know that numerous instances may be quoted in which students have presented the usual evidence of having diligently fulfilled the four years of their curriculum of study, and obtained their diplomas almost with honour after the usual examinations, though they had been engaged behind desks in banks or counting-houses for the entire working day during which their lectures and hospital studies were supposed to have been attended; and the career of students thus licensed to kill or cure has sometimes followed to their appointment within a few months as hospital surgeons and clinical teachers, in which capacity they, for the first time, commenced the true study of their profession. It is a well known practice for the needy students to undertake service behind an apothecary's counter, and to continue in that employment steadily and regularly engaged in dispensing and attending to the shop business until within a few months of the time of their examination, at which period, having saved up by their service behind the counter a sum sufficient to pay for their certificates of diligent attendance at hospitals and lectures, and for the services of an experienced "grinder" they leave the service of the apothecary, submit themselves to a hasty "cramming," and are in due time impressed with the stamp of medical competency by a licensing corporation.

These are naked truths which must be told, for they afford the reasons for a proposal of reform in the system of medical education, which, if not justified by such facts, might be considered revolutionary and destructive.

The means at our disposal for ensuring the competency of the medical practitioner are twofold:—

1. To require from him documentary proof that he has

Digitized by Google

studied his profession under the instruction of competent teachers, has had ample means of acquiring practical experience, and has availed himself of these opportunities during a sufficiently extended period of time.

2. To satisfy ourselves by examination that he has actually grasped the knowledge thus presented to him to such an amount and in such form as to enable him to treat disease for the public advantage.

The causes, therefore, which must be held responsible for the possibility of such facts as we have stated, and for the insufficiency of our qualifying system are also twofold.

(*a*) The complete insufficiency of the pre-examinational proofs required from the student as to his actual fulfilment of the curriculum of study.

(*b*) The insufficiency of licensing examinations, whether in respect of their frequency, the period at which they are held, or their character as tests of the competency of the student for practice.

Although there exist wide differences of opinion as to the relative value of curriculum and examination as evidences of competency, our system (and in a greater degree the system of all European nations) acknowledges the insufficiency of either form of proof *per se*.

No qualifying diploma is granted in any country upon examination alone, it being felt, no doubt, that the question of the competency or incompetency of a medical practitioner is too grave to stake upon any one item of proof, and that it would be impossible to construct an examination within any reasonble limits of extent or duration which would of itself be enough to guarantee the practical efficiency of the practitioner; moreover the competency of the medical man is in so great a degree arising out of his personal observation, and out of the actual practice of his finger, his eye, his ear, and his mind, that the proofs of such personal observation ought not to be dispensed with, especially as it is hardly within the range of a limited examination, however perfect it may be, to ascertain with certainty that he possesses that quality.

(*To be continued.*)

POOR-LAW MEDICAL OFFICERS' SUPERANNUATION FUND.—II.

We have now to consider the practical working out of a scheme for a superannuation Fund, taking as our basis our returns obtained from the Poor-law medical officers of Ireland; and as we may presume that what is true of a part is true of a whole, our principles may be applied to the united service in Great Britain. From our data it will be seen that the typical Poor-law medical officer receives his first appointment in the service at 28½ years, that in three years' time he marries, and children will be born in the usual rotation, to the number of 4·37, of whom perhaps one will die before attaining the age of 21.

The Poor-law medical officer will die at the age of 61, leaving probably a widow, at the age of 50, and 1·50 children of an average age of 14 years, chargeable to the fund, for a period of 7 years.

What deduction from salary would enable the managers of any fund to grant annuities of £20 and £10 respectively to widow and children?

Government mortality tables give to a man of 30 years of age an expectation of 33·7 years of life, that is, he is not expected to die until he reaches the age of 63·17 years. The average Poor-law medical man is supposed to become a member of the Fund at the age of 28·6 years, at which time his wife would be 27, and her expectation of life would be 38·7 years, or in other words she would be nearly 59 years of age at the death of her husband, and may be expected to live until the age of 66 or 68.

We can purchase for a sum of £184 in a first-class insurance company an annuity of £20 for a widow in her 59th year, and by a further sum of £105 we can provide £15 a year for 7 years for a child at the age of 14. Can we by a small deduction from salary apply it in another way—sufficiently provide an allowance for widows and orphans?

Bearing in mind all the facts and circumstances mentioned previously, we may summarise the account of the responsibilities of such a fund as follows:—

Total number of Poor-law medical officers in Ireland	1,019
Deduct 12 per cent. who will never marry	123
Number who marry	896
Deduct 38 per cent. for those who outlive their wives and leave no widows	387
Number of those who leave widows	509

Mortality of this number, annually, at 1½ per cent. (7·60), say eight.

Mr. Hancock, the secretary and actuary of the Patriotic Insurance Company, has assessed the actual mortality amongst the Poor-law constituency at 1½ per cent., the question being submitted to him by Dr. Darby, though this is a higher rate than that usually estimated for professional men.

Assuming, then, this estimate to be correct, 8 widows will be chargeable to the fund, and from our calculations they will be 59 years of age with an expectancy of life of 7½ years.

They will come upon the fund according as their husbands die off, 8 in each year, until at the end of 7½ years there will be 60 receiving annuities.

At £20 a year each the charge for them therefore will be, for the first year, £160; for the second year, £320; for the third year, £480, and so on, increasing £160 yearly until 7½ years shall have expired, when their numbers will have increased to 60 and their charge £1,200 a-year.

We must now consider the children, and a much larger charge must be calculated for them, because a certain number are expected to survive both father and mother.

As we have previously shown, the married medical men will have on an average 4·37 children, which number will be reduced to 1½ each by early death, and by the elder children passing the limit of 21 years, up to which age the fund is chargeable with them.

From the law of averages, or an annual mortality of 1½ per cent. amongst the 896 medical men who marry, 20 children at the average age of 14 may become chargeable to the fund until they reach the age of 21.

Digitized by Google

At £10 a-year each the charge for them will be as follows:—First year, £200; second, £400, and so on until the 7th, when the permanent charge will be £1,400—20 new orphans coming on the fund each year to supply the place of the twenty who reach the age of 21. The permanent account will then stand as follows:—

For allowance to 60 widows . .	£1,200
„ „ 141 children . .	1,410
	2,610
Add working expenses, say . . .	250
	£2,860

If we divide this sum over the 1,019 medical men, it will require a deduction from each salary of £2 16s. 1d. yearly, or 14s. 1d. per quarter.

This sum, then, is the minimum deduction which should be made to meet the demands, but it should be assessed on the sliding scale—least for the medical officer who joins the fund immediately on his appointment, and greatest for him who waits until he has encumbered the fund with liability for his wife and child.

Such a table is easily constructed. Suppose a subscriber to contribute £2 16s. 1d. yearly from his 29th to his 62nd year, he will on his death at the latter age, have paid altogether to the fund £92 10s. 2d. Our tables should be therefore constructed so that all subscribers, no matter what age, would, on reaching their 62nd year, have contributed a similar sum, *i.e.*, a subscriber of 40 must pay a yearly amount which will make up the same sum in 22 years—one of 45 in 17 years, and so on.

TABLE OF DEDUCTION FROM SALARY FOR EACH AGE FROM 29 TO 50.

Years of Age.	Yearly.	Quarterly.
29	£2 16 1	£0 14 1
30	2 19 8	0 14 11
31	3 1 8	0 15 5
32	3 3 10	0 16 0
33	3 6 2	0 16 6½
34	3 8 6	0 17 1
35	3 11 2	0 17 6½
36	3 14 0	0 18 6
37	3 17 1	0 19 3
38	4 0 5	1 0 1
39	4 4 0	1 1 0
40	4 8 1	1 2 0½
45	5 15 9	1 8 11
50	8 8 3	2 2 1

In our next concluding article we shall consider the reserve fund and the difficulties in the way of the realisation of such a scheme, but we must remember that difficulties are only made to be overcome; so we trust that they may not prove insurmountable, and that we may be able to show the way out of them.

Notes on Current Topics.

Expulsion of a Dental Licentiate from the Irish College of Surgeons.

THE Council of the Royal College of Surgeons in Ireland has recently availed itself of the powers granted by its charters to erase from the list of its Licentiates the name of a person who had obtained his licence upon a false statement or wilfully violated the regulations of the College. The section of the charter under which the Council exercised this power runs as follows:—

"And We do hereby, for us our heirs and successors declare and direct that if it shall at any time hereafter appear that any Licentiate or Fellow of the said College shall have obtained his Letters Testimonial, or his Diploma by any fraud, false statement, or imposition, or that either before or after obtaining such his Letters Testimonial or Diploma, he shall have wilfully violated any Bye-law, Rule, or Regulation of the said College, then, and in every such case, and after such previous notice to and such hearing of such Fellow or Licentiate as under the circumstances the Council of the said College shall think proper, it shall be lawful for the Council to pass such judgment or censure upon the person so offending or (in case it should seem expedient) to recall or declare the Letters Testimonial or Diploma respectively of such Fellow or Licentiate to be void, and therefore every such Licentiate or Fellow shall accordingly cease to be Licentiate or Fellow of the said College as the case may be."

The person to whom the operation of this section was applied was a certain John Hamilton, residing at 7 Tavistock Street, Bedford Square, London. He was admitted a Licentiate in Dental Surgery of the College on the 3rd of February last, in the character of a dentist of twenty-six years' standing. That he was of good moral character and that he had not for two years previously "attracted business as a dentist by advertising or other unbecoming practices" was testified (as the regulations require) by two licentiates of a College of Surgeons, Mr. J. H. Bannister, 436 Oxford St., and Mr. F. J. Hammond, M.R.C.S., of 18 The Terrace, Kensington Gardens Square, W., and by "two dentists of repute," who in the present case were Mr. James J. Nottingham and Mr. James Henry Trist, of 82 Judd Street, London.

On receiving the diploma, Mr. John Hamilton made the usual declaration, "that he would not attract business by advertising or any other unbecoming practice," and agreed "that such diploma should be cancelled on it being proven that he had done so." Despite this declaration, it came to the knowledge of the Council that pamphlets and circulars of the character usual with a certain class of practitioners were distributed at Mr. Hamilton's shop, and these pamphlets being before them, together with other evidence of similar import, it was decided, on the recommendation of the Board of Dental Examiners, to call on him to show cause why he should not be struck out of the College books. His explanation being deemed to be altogether unsatisfactory, both by that Board and by the Council, it was formally resolved that Mr. Hamilton's licence be cancelled, and that he be required to return it to the College for such purpose.

This, in spite of his declaration that he would do so, he refused to do; but the Council of the College has officially informed the Medical Council of his amotion. The effect of this proceeding will be, we believe, to strike his dental licence out of the Dental Register, but the removal of his name from the List of Dental Practitioners must be the work of the General Medical Council, which body is empowered, by the 13th section of the Dentists'

Digitized by Google

Act, to "erase any entry incorrectly or fraudulently made." It shall also "on the application of any of the medical authorities, cause inquiry to be made into the case,' and, "on proof of such infamous or disgraceful conduct," erase the name.

If the Medical Council, acting upon this authority, should strike Mr. Hamilton's name out of the Register, he will cease to be entitled to practise dentistry, and may be prosecuted if he continues to do so.

A Recurrent Nuisance.

EACH advent of cold weather with frost brings with it a nuisance that is to blame for many of the casualties that crowd the receiving rooms of hospitals in winter. We allude to street sliding, and especially because several severe accidents have, within the last few days, been reported as due to street passengers slipping on slides made along the pavement. How dangerous these are all must be familiarly aware; but how frequently they are met with in some places all do not know. The police should have strict injunctions to take in hand all boys who endanger the public safety by indulging their sliding propensities in the highway.

In the same category may be included the slippery iron traps which cover over the coal-cellar entrances, and occur at frequent intervals along the pavement. We have known several very severe accidents due to falls caused by these traps for the unwary; and they are the more prolific of disaster since a little rain makes them just as slippery as a sharp frost. The grids which replace the smooth plane covers in some districts, though not so likely to produce serious mishap, are yet very unsafe in such weather as the present; and we think it time that some new means of closing the openings in the pavement—a means less likely to provoke danger to life or limb—should be adopted into general use. It is in little things like this that the test of local government is to be found. In this instance we must dub it unsatisfactory.

Home Hospital Association.

THE judgment against the Home Hospital Association, and in favour of Lord Portman, affects the interests of the profession to a considerable extent. By the nature of the lease under which the Association held their tenure of the premises in Manchester Square, no medical man with similar holding could have in his house, even temporarily, a patient from whom he expected to receive a fee for treatment. Apart from the question of the hardship removal must entail on the institution, other considerations are provoked by the recent decision. There seems no other plan open to such an association but the building of premises on land of which they themselves hold possession, unless the appeal now being made proves successful. There can be no reasonable objection raised against the hospital on hygienic grounds. No infectious cases are admitted into it, and greater immunity is therefore secured to the neighbourhood in which it is situate than by the presence merely of private houses, for in any one of them, at any time, fever may break out, and the case can then be nursed, it may be immediately under the shadow of Lord Portman's town residence. We cannot but think the exercise of the undoubted "rights" of the lessor of the ground has been an ill-judged act, and likely to be productive of possibly less good results than was anticipated by the owner of the property in Manchester Square.

The late Mr. Harry Leach.

AN energetic advocate of the importance of a study of public health has lately passed from our midst, in the person of Mr. Harry Leach, M.R.C.P., who died on Wednesday, Nov. 26, at his residence in Albert Mansions. Mr. Leach did eminent service in directing attention to the prevalence of scurvy among sailors, and his untiring efforts resulted in such amendment of the Merchant Shipping Act as has been followed by the most beneficial results. In 1870 Mr. Leach was appointed Chief Medical Officer to the Dreadnought Hospital, he having been principally the means of its removal to Greenwich from the old useless hulk in which it had to that date been located. Resigning this post in 1873, Mr. Leach was chosen to fill the newly-created post of Port Medical Officer to the City of London, and in 1876 he was elected one of the Visiting Physicians of the Seamen's Hospital, which owed so much to his interest in its behalf. The disease to which Mr. Leach succumbed was an old-standing pulmonary affection, and twice he sought the relief afforded by residence for a time in South Africa. He died as so many true, good men have died of late, in harness, intent to the last on extending the usefulness of his days. The amount of service he rendered to the working world will be not soon forgotten, and many will long mourn the honest, ready friend who never refused his aid to an honest and worthy cause.

Poison Vending.

OUR contemporary the *Pharmaceutical Journal*, in an article under the above heading, has, we regret to say, been unwise enough to make a virulent attack on us for bringing to light the great evils that are the natural consequence of the existing law relating to sales of poisons. We can readily understand the unwillingness of the Pharmaceutical Society to resign the authority it has possessed for so long; and we are glad that no attempt has been made in the article referred to to justify the retention of this power in its hands. So forcibly have we exposed the evil that even the writer of the reply has felt constrained to quote largely from our columns to his own destruction. Notwithstanding all this, however, we would caution our contemporary against weakening the cause it must defend by silly ebullitions of splenetic virulence. We are willing to discuss the question calmly and fairly, but we cannot descend to a mere war of words.

The Pauper Poison.

Is pauperism hereditary? or does it depend upon our social surroundings and our customs? or is it a moral poison which we ourselves foster, rendering ourselves responsible for the results over which we have so many complaints, and about which so much has been written? These are very important questions. The profession is painfully interested in pauperism, for it has been publicly declared over and over again that one-fourth, or upwards of 1,000,000, receive gratuitous medical treatment in London (Sir C. Trevelyan), and that our population has

Digitized by Google

been pauperised by the medical profession ; for according to the first report of the Medical Committee of the Charity Organisation Society, "there is no one class of charities which is doing so much to pauperise the population, to undermine their independence and self-respect, and to discourage habits of providence, as the medical charities."

The moral poison which leads men and women to our hospitals and charities, is a sure indication of its presence in our social fabric, but it is only one form of it. It may be seen in every part of our social life, and we are afraid we shall see it more in the future, after we have educated our young generation in what are virtually pauper schools, where education is given for nothing, and where what is most valuable is thus lowered, so that by a very easy descent and computation, the receiver of State aid in childhood, will look for further assistance in other things less valuable, and the spirit of pauperism will take such a firm foothold that it will be impossible to eradicate it.

One of the great tendencies of our age is to get something for nothing ; it may be place, power, position, or fame, so that the contaminatiug influence of the social miasma is not confined to one strata of society.

To whom does the Fœtus belong?

Our Parisian contemporary, *Le Praticien*, of Nov. 24th, records an accident, provocative of considerable commotion among the unmarried ladies present. The occasion was a ball given in honour of a wedding at the *mairie* of a small French town. In the middle of the ball, one of the dancers stooped down, and pulled up a strange mass, which on examination by a *sage femme*, who was present, was declared to be a fœtus. There was great emotion, and the question came, whom to suspect and to whom did it belong? There were a number of young ladies, unmarried, and it would be difficult to make a special examination of them all. The difficulty was, however, eventually solved by a newly-married lady who was present, confessing that she was the late proprietress of this veritable apple of discord, and according to *Le Praticien*, it had passed from her without any pain or warning of the occurrence.

On the Transmissibility of Hydrophobia.

At the last monthly meeting of the Academy of Medicine of Paris, M. Maurice Raynaud presented a small *brochure* relative to the transmission of rabies from man to the rabbit. In his service at the Hôpital Lariboisière, Dr. Raynaud had the sad yet good fortune to have a patient suffering from hydrophobia. On the eve of the patient's death, M. Raynaud inoculated some of the blood and saliva of his unfortunate patient into some rabbits. The inoculation of the blood gave rise to negative results, but the inoculation of the saliva produced rabies in a very short time.

Besides this, M. Raynaud extirpated the two submaxillary glands of two of the rabid rabbits, and inoculated them into two other rabbits perfectly healthy ; the results were perfectly positive, and the inoculations were followed a little time afterwards by the manifestation of rabies. Science has not yet registered a single instance of the transmissibility of hydrophobia from man to man, but M. Raynaud, relying on the proofs we have of its transmission from man to animals, believes that if accidental inoculation took place from man to man, hydrophobia would inevitably develop.

In our "Reports on Rabies and Hydrophobia" we have adduced facts somewhat similar to the above.

Guy's Hospital.

We understand that no change for the better has yet taken place at Guy's Hospital. And spite of a contemporary's announcement that the question is a mere students' affair, we can speak decidedly against such a view of the matter. To such an extent is it a question involving the interests of the institution and the relations subsisting between it and the medical and surgical staffs, that very serious indications of a determination to resist the innovations by adopting extreme measures is hinted at on the part of the staff as a whole. It is true that many valuable servants have left the hospital rather than submit to the conditions of service imposed by the new matron. Among these we find that the night nurses are directed to turn out patients at five a.m., in order that the beds may be made before they go to breakfast. Day nurses are required to rise at 5.30 instead of 6.30, and then, instead of immediately getting breakfast, as under the old regulation, they are compelled to wait until eight o'clock for the meal. Also, in place of going out in the evening, the nursing officials are ordered to leave their places only during the afternoon, the effect being that at the busiest time of the day the wards are left most inefficiently provided with attendants. These are only samples of the new orders. Under them an approaching *stasis* at Guy's is imminent.

The Metropolitan Hospital Saturday Fund.

At the final meeting of the Council of this Fund for the present year, held at King's College Hospital on Saturday last, a preliminary discussion was raised on the question of the direct representation of the Society on the Boards of Hospitals and Dispensaries. Ultimately the following motion was agreed to with one dissentient :—"That the Council of the Hospital Saturday Fund, as subscribers to the various hospitals of London, are entitled to all the privileges accorded to other subscribers, and that the necessary steps be taken to secure such privileges." The report of the Council stated that in spite of the depression in trade more than £6,500 had been obtained in subscriptions, and the working expenses had been less than in previous years. The Chairman moved the adoption of the report, and the resolution was adopted. A further report stated that 96 institutions had shared in the benefits of the fund.

The Howard Medal.

This year a lady has carried off the Howard Medal. At the first meeting of the present session of the Statistical Society the Medal and £20 were presented to Miss Beatrice A. Jourdan, as the writer of the best essay "On the Improvements that have taken place in the Education of Children and Young Persons during the Eighteenth and Nineteenth Centuries." The subject of the essay of next year is "The Oriental Plague, in its Social, Economical, Political, and International Relations."

Healthy Homes.

In a recent issue we drew attention to "The Homes of Medical Men," pointing out that as the public looked to the medical profession for guidance in matters pertaining to health, its members should first show faith in the doctrines they tried to inculcate in others by seeing that their own homes were as healthy as sanitary knowledge could make them; and thus, possessing the force of example as well as precept, they would stand a better chance of winning their patients over to like principles. On Saturday last we, in company with some forty or fifty representatives of the medical, sanitary, and lay press, were invited by Mr. Morris, the owner of the property, to a noble villa in the west-end of Brighton, in which Dr. Hayward, of Liverpool, was to deliver a lecture, on the principles and applications of warming and ventilation of houses, on plans invented by Dr. John Drysdale, of Liverpool, and himself. The villa in question—the first of the kind in Brighton—had been erected with these special appliances, and was opened on Saturday as a test house, prior to the adoption of the system on other parts of the estate. The main essentials of Drs. Drysdale and Hayward's plan may be thus summarised:—The suction power for efficient ventilation must be sufficient to empty the whole house every twenty or thirty minutes; it must be constantly in operation; it must be automatic or self-acting, it must abstract from every room equally; and it must be inexpensive; the fresh air must enter each room in sufficient quantity to fill the room every twenty or thirty minutes, and it must enter imperceptibly and at a temperature not lower than 60 deg. F.; it must therefore enter the house by a special opening, and be warmed as it enters in some central or separate lobby, hall, or other reservoir.

These conditions have been met in the houses these gentlemen have built for themselves in Liverpool, and having stood the test of several years' experience they are naturally desirous of seeing them adopted throughout the country, especially in the homes of their fellow practitioners. The principles are equally applicable to old houses as in the construction of new ones, though in a less perfect sense. One thing, however, is absolute—namely, that the kitchen fire, or rather the waste heat of the kitchen fire, shall be utilised as the suction power, the kitchen fire alone in every house being lighted daily throughout the year, no other means of suction power for house-ventilation being costless and automatic. Of course, it is quite necessary that the suction power shall draw equally from all the rooms at the same time; but in procuring this a mechanical difficulty presents itself—namely, that of the source of the power being single—*i.e.*, the kitchen chimney—whilst the rooms are many, and at different heights and at different distances from it. Of course, if the exit flues of the different rooms entered the upcast at different heights, the suction power would act more strongly on some than others, if not on some to the exclusion of others. This difficulty has been overcome by having a central or intermediate chamber or drum into which all the exit flues terminate, at the same level, and from which one single flue leads into the upcast.

In reply to a question as to cost of maintenance of this system of warming, Dr. Hayward stated that it cost him in his own house but fivepence yer twenty-four hours for coke, which was much more than saved by the need of less firing in the rooms.

To our minds the system is the most perfect yet devised and as we are unable to devote more space to it in our columns, we would refer our readers to a book entitled "Health and Comfort in House Building," published by Messrs. Spon of London, in which they will find the matter fully illustrated and explained.

The lecture over, the company were invited to examine the results of the system throught the house, whilst Dr. Hayward explained the details and answered the many questions put by a severely critical audience. An excellent *déjeuner* at Prince's Club wound up a very pleasant and instructive gathering.

Sanitation in Country Towns.

We recently discussed in a leading article the deficient legislation with respect to the enforcement of sanitary precautions in villages and small towns. A case to point the moral we then drew has just been brought to our notice; and as it applies with much force to the whole question involved, we think is worth re cording here. The refuse from a gas-works at Redruth in Cornwall flows into a small rivulet, or "leat," by which channel it is conveyed through a portion of the town; and as we remember it, the stream flows directly past the backs of a number of cottages, and beneath certain larger houses, one of the latter being occupied by a medical practitioner, Mr. Harris, F.R.C.S. According to this gentleman's statement, the stench from the refuse-charged water is at times unbearable, and as we formerly indicated, in such a case the nature of the effluvium is decidedly injurious to health. Rightly enough, Mr. Harris complains of the nuisance, and demands its abatement through the assistance of the local-authority. The "board," in sympathy apparently with the gas manufacturer, and with the concurrence of the "Inspector," declines to act in the way of suppressing the nuisance, urging as a reason for its course, the fact that, on the occasions of his visits of inspection, their officer failed to distinguish the smell of which complaint had been made. The collective wisdom of this "local board," is not capable of grasping the truth that should be apparent to every rightly educated parochial authority, that, viz. nothing offensive, or capable of generating offensive, or noxious gases, should be permitted to come within a given (wide) distance of any dwelling house. And further, the cumbrous machinery explained to them by their legal adviser is by them deemed the only engine wherewith it is open to them to effect the simple and rational cure of the evil complained of. The deflection of the water-course, if it *must* be the channel of the hurtful products of gas-making, would strike any ordinary observer as the obvious remedy for the nuisance. And were a Government officer appointed to direct the efforts of the parish magnates in the right path, there can be no doubt that one of his first acts would be to effect this very necessary measure of reform in Redruth. This is only one out of a number of serious nuisances of the kind in country places, that we have seen and felt the necessity for the removal of, in the interests of public health. The mortality of Redruth is not ex-

Digitized by Google

travagantly high ; but it might be considerably decreased under a proper hygienic *régime*.

Health of Dublin.

THE deaths registered in the Dublin Registration District during the week ending 29th November, represent an annual mortality of 31·2 in every 1,000 of the population. The average of eight large town districts of Ireland (including Dublin), last week was 27·6. In 20 large English towns, inclusive of London (of which the rate was 26·0), the death-rate averaged 25·2 per 1,000 ; in Glasgow, 16·6 ; and in Edinburgh, 20·2.

The number of deaths from zymotic diseases registered is 44, being 13 over the average for the corresponding week of the last ten years, but 3 less than the number for the week ending 22nd ult : they comprise 2 from small-pox, 4 from measles, 15 from scarlatina, 1 from diphtheria, 2 from croup, 3 from whooping-cough, 7 from fever (1 typhus and 6 typhoid), 1 from erysipelas, 5 from diarrhœa, &c.

Fourteen of the 44 deaths from zymotic diseases occurred in Denzille Street district, where the 22 deaths from all causes include 6 from scarlatina, 3 each from fever and measles, and 2 from diarrhœa ; the mortality from these four diseases being equivalent to an annual rate of 17·9 per 1,000 of the district population. Scarlatina has been prevalent in this district for some months—two of the fatal cases recorded last week occurred in the same house in Townsend Street. Fever caused 4 deaths in this district in the preceding week, but for some time previous there had been but few deaths from that disease. It may be added that 19 of the 22 deaths in this district last week were of children under 10 years of age.

The registered deaths from small-pox in Dublin are 5 under the number for the preceding week, and the new cases of the disease admitted into the City hospitals, which in that week amonuted to 26, fell last week to 17. Nineteen patients were discharged during the week, 4 died, and 73 remained under treatment on Saturday last, being 6 under the number in hospital at the close of the previous week. The deaths from scarlatina are similar in number to those for the preceding week, but only 11 new cases were received in the principal hospitals against 16 in that period. Four cases of typhus, 6 of typhoid fever, and 7 of pneumonia, were admitted into the principal hospitals. The respective numbers for the preceding week were 2, 10, 4.

Army Medical Department.

A MEDICAL contemporary says that somewhat more than 80 candidates have presented themselves. As to their nationalities, so far as these may be defined by places of birth, Irish and English (the former slightly preponderating) form the majority ; next, those born in India or British colonies, these being chiefly the sons of officers on duty abroad ; very few are of Scotch birth. Of the London schools, Bartholomew's, St. Thomas's, Guy's, University College, and St. George's furnish the greater number. Of the Irish, the majority are from the Queen's Colleges, Cork and Belfast ; Trinity College, Dublin, and the Royal College of Surgeons School. The colonials were educated and qualified, as a rule, in Edinburgh or London. We understand that the candidates, professionally, socially, and physically, are remarkably good ; several are the sons of officers in the combatant or medical branches of the army. Many have university degrees, and are men of high general culture, and not a few have "smelt powder" in the Cape War. No information has yet been accorded as to the number of vacancies to be submitted for competition. The examination began at 10 a.m. on Monday last, the 8th inst., at the Law Institution, Chancery Lane.

Anuria.

IN the *Union Médicale* for November 4, Dr. Dubuc relates a case of anuria in which the patient lived for seventeen days without having expelled a single drop of urine. He died on the seventeenth day with symptoms of uræmic intoxication, but no autopsy was permitted.

The New Sydenham Society.

THE Council of this Society have resolved to reprint the classical work on "Diseases of the Chest," by the late Dr. William Stokes, of Dublin. The editor of the work will be Dr. Alfred Hudson, Regius Professor of Physic in the University of Dublin.

The Brown Institution Lectures.

THE lectures in connection with the Brown Institution will be delivered by Dr. Greenfield, at the University of London, on December 17, 18, 19, 22, and 23, at 5.30 p.m. The subject of the course will be, "Recent Investigations on the Pathology of Infectious and Contagious Diseases."

SURGEON-MAJOR CUFFE has been commanded to proceed to Windsor, to receive from her Majesty the insignia of a Companion of the Bath, conferred on him for distinguished services with Wood's Flying Column in the late Zulu war.

THE Court of the University of Edinburgh announces that it will, on the 26th of January, proceed to the appointment of the additional Examiners in the University in the Departments of Botany, Natural History, and Practice of Physic.

ROME is at the present time in a most unhealthy state, having the highest death-rate, the notorious fever-den, Alexandria, alone excepted, of any city in the world. A mortality of 40 per 1,000 is likely to deter many from leaving this country to spend the much advertised "Christmas in Rome."

THE will of the late Mr. George William Callender, F.R.S., Surgeon to St. Bartholomew's Hospital, who died on the 20th ult., at sea, on board the steamship *Gallia*, was proved on the 17th Nov. by the Rev. Richard Clement Callender, the brother, the sole executor. The testator leaves all his property to his executor, upon trust for his children.

A SOCIETY has been started in London for the prevention of reckless driving, and for the supply of ambulances at the corners of the streets, so that those who meet with

Digitized by Google

accidents may have a comfortable journey to the hospital. We do not like to throw cold water on well-meant efforts, but really philanthropy seems to have outdone itself in th instance; the fact of seeing an ambulance at every corner will not enhance the pleasure of a walk through the streets of London.

In the principal large towns last week the rates of mortality per 1,000 were—Portsmouth 15, Bradford 17, Glasgow 17, Sunderland 20, Edinburgh 20, Newcastle-upon-Tyne 21, Oldham 22, Brighton 22, Norwich 22, Sheffield 22, Leicester 22, Salford 24, Birmingham 25, Manchester 25, Wolverhampton 26, London 26, Bristol 26, Leeds 27, Nottingham 27, Hull 28, Liverpool 29, Dublin 31, and the highest rate in the United Kingdom 34 in Plymouth.

The death-rate from the seven principal zymotic diseases averaged 4·2 per 1,000 in the principal large towns in the United Kingdom, and ranged from 0·5 and 0·7 in Oldham and Wolverhampton, to 5·5 and 5·8 in Leeds and Liverpool, 6·1 in Dublin, and 7·0 in Plymouth. Scarlet fever showed the largest proportional fatality in Leicester, Nottingham, Bristol, Dublin, and Newcastle-upon-Tyne; measles in Liverpool, Plymouth, and Leeds. Diphtheria caused 8 deaths in London and 2 in Birmingham. Four fatal cases of small-pox were recorded in London, 2 in Dublin, but not one in any of the other large towns.

In the principal foreign cities the rates of mortality according to the most recent weekly returns were—in Calcutta 24, Bombay 33, Madras 35; Paris 24; Geneva 16; Brussels 26; Amsterdam 21, Rotterdam 21; The Hague 16; Copenhagen 36; Stockholm 19; Christiania 18; St. Petersburgh 32; Berlin 22, Hamburg 25, Dresden 21, Breslau 19, Munich 33; Vienna 24; Buda-Pesth 30; Rome 40, Naples 27, Turin 30; Alexandria 44; New York 24, Brooklyn 22, Philadelphia 14, and Baltimore 20 per 1,000 of the populations. Small-pox caused 19 deaths in Paris; measles 36 in Copenhagen; and diphtheria 29 in Berlin.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

The deaths in Glasgow for the week ending the 29th ult. were at the rate of 17 per 1,000 per annum, against 21 in the preceding week, and 25, 25, and 27 in the corresponding periods of 1878, 1877, and 1876.

Health of Edinburgh.—There were 85 deaths registered last week in Edinburgh, as against 72 the preceding week. The death-rate is 20 per 1,000. More than half the mortality was due to diseases of the chest. The zymotic deaths amounted to 8, only 1 of which occurred in the New Town, while the southern suburbs were entirely free. Of the persons who died 16 were above 16, and 3 above 80, years of age.

Principal Caird on the Western Infirmary, Glasgow.—The present position of the Western Infirmary, Glasgow, strikingly illustrates the inevitable consequences of indiscriminate medical charity, and the too willing obedience to demands thus made by increasing the facilities of treatment as the applicants for treatment increase. Principal Caird truly remarked that gifts of money may stimulate poverty, but he is not quite so logical or relevant in the statement that "gifts of healing can never stimulate disease." This is true enough in a sense; but unbounded invitation to the general public to be treated at hospitals increases the number of applicants, robs the junior members of the profession, demoralises the public, and, just as "money gifts," stimulate poverty and crime. According to Dr. Caird, the financial position of the infirmary is far from healthy. During the past year the patients treated have increased in number by more than a thousand (944 indoor, 99 outdoor), and the ordinary revenue fails to meet the expenditure by more than £2,000. This renders, says Dr. Caird, the outlook for the future a very anxious one. In the face of all this it is difficult to characterise the conduct of the authorities in adding to the hospital almost double its existing accommodation, and thus entailing an enormously increased cost of maintenance. In this state of things it is suggested that not a few are beginning to ask why such an institution should not be maintained by a public rate, to which all would be compelled to contribute according to their means, rather than be left to precarious charity, a method of support according to which the selfish and stingy escape at the expense of their more benevolent neighbours. We wonder what the humbler class of practitioners would have to say to the prospect of such a tax. It is not to be supposed that they would regard the shutting up of at least the ont-door department of the hospital with any feelings of regret.

Professor McKendrick on Alcohol.—On the evening of the 27th ult. Professor McKendrick delivered the inaugural address on this subject to the Glasgow University Total Abstinence Society, in the Physiology class-room. There was a large attendance of students, and the subject was treated in a very interesting and comprehensive manner.

The Scientific Evidence of Organic Evolution.—On the 28th ult. Mr. G. I. Romanes delivered his second lecture on the above subject at the Edinburgh Philosophical Institution. After describing Dr. Darwin's theory of natural selection, Mr. Romanes said the first thing to be observed with regard to that theory was that it offered a scientific explanation of the numberless cases of apparent design everywhere met with in organic nature, for, as all these cases of apparent design consisted only in the adaptation which was shown by organisms to their environment, it was obvious that the facts were covered by the theory of natural selection no less completely than by the theory of intelligent design. Let them once admit the glaringly illogical principle that the operation of the higher causes might be assumed when the operation of lower ones was sufficient to explain the observed phenomena, and all science and philosophy were scattered to the winds. For the law of logic—which Sir William Hamilton called the law of parsimony—or the law which forbade us to assume the operation of higher causes when lower ones were found sufficient to explain the desired effects, that law constituted the only logical barrier between science and superstition. Having dwelt at length on the evidence in favour of natural selection, dealing with the arguments from classification, morphology, geology, and embryology, the lecturer said the question eventually became narrowed down to "man or monkey," and it was only a few months before birth that an embryologist could pronounce the young animal to be lord of creation. The principal obstacle which the doctrine of evolution encountered in the popular mind was that the conception of man being the lineal descendant of the monkey was a conception degrading to the dignity of the former animal. Now the ob-

Digitized by Google

jection was purely a matter of sentiment, and as such he was not able to meet it; but sentiments were quite worthless as arguments or guides to truth. He had yet to learn that the dignity of man was a matter of any concern to Mother Nature, who, in all her dealings appeared, to say the least, to treat us in rather a matter-of-fact sort of way. Those who advanced this preposterous objection from dignity appeared to forget the all important fact that, whether or not the monkey was parent of the man, the man was certainly made in every way to look like a child of the monkey, for it was a matter of anatomical demonstration that in all the features of our bodily structure, even to our brains, we more closely resembled the man-like apes than the latter resembled the lower quadrumana. As reasonable beings we must conclude that there has been some definite cause for this extraordinary imitation by the most highly organised being in Creation of the next most highly organised. And if we rejected the natural explanation of hereditary descent we could only suppose that the Deity, in creating man, took the most scrupulous pains to make him the image of the ape. Why should God have thus conditioned man as an elaborate copy of the ape, when we know from the rest of creation how endless were his resources in the invention of types? To him it appeared that the question was as unanswerable as it was unavoidable. The only other objections to Darwinism that he knew of were those raised by theology. He did not deny that Darwinism, by cutting away the argument from design, had dealt a heavy blow to natural, as distinguished from revealed, theology; but further than this he could not see any reason for the theologians to quarrel with the naturalists. To him it seemed that the first Chapter of Genesis might be made to teach the doctrine of evolution quite as well, if not better, than the doctrine of special creation; and as far as the manufacture of Eve was concerned, he believed that even before Darwin's days enlightened theologians did not care to be very dogmatic about its literal interpretation. It seemed, then, that the only rub between theology and Darwinism consisted in the latter destroying the argument from design. But he should like, in conclusion, to point out that even in this respect theology would not be altogether a loser, for now that the science of biology had made so much progress, it must really, he should think, be a relief to thoughtful and candid theologians that Darwinism had stepped in to remove from them the responsibility of justifying the way of God to man, For the design argument suffered the intelligent contriving of organic structures for the uses to which they were put; and, therefore, how fearful was the unavoidable inference that in thousands of cases the Deity had deliberately planned elaborate mechanisms for the express purpose of inflicting pain and death! He did not know a thought more terrible than this, and in the face of it he should find it impossible to regard the Deity as benificent. The whole creation groaned in pain and travail, but if we saw reason to believe that such a state of things was due to the operation of general principles of government, rather than to special designs of Creation, it seemed to him we had a better basis for the trust of God's love.

A Clerical Parochial Doctor.—The Parochial Board of Holms, Orkney, have appointed the Rev. Daniel McNeill, L.F.P. & S.G., Free Church Minister, Medical Officer, in room of Dr. Bruce, Kirkwall. It was stated that, though a member of the Board, the Rev. gentleman would act for about half the sum paid to the present medical officer!

Glasgow University.—The Lord Rector.—Mr. Gladstone arrived at Glasgow on the evening of Thursday, the 4th inst., and received a right royal welcome from the students of all political shades of opinion. Their torchlight procession was particularly effective, and their conduct altogether exemplary. The day following the right hon. gentleman delivered his rectorial address in the Kibble Palace in the presence of an audience of close upon 6,000 people, chiefly composed of students and members of the University Council. This is not the place to discuss the address, suffice it to say that it was listened to with the utmost attention; that it was brilliant in conception and delivery, though not a little of it—particularly the defiant attitude against science in relation to christianity—was open to the easiest contention. We regret to be obliged to draw attention to the fact that the venerable President of the Faculty of Physicians and Surgeons was seen in the general crowd and crush of the members of Council. If there was no courtesy due to his present office, was there none to be expected from that university which he so long, so lovingly, and so faithfully served?

Jubilee to Dr. Kew, Perth.—On the afternoon of the 5th inst. Dr. Kew, Perth, was entertained to dinner on the occasion of his attaining the 50th year of his practice as a physician. Mr. Robert Martin, solicitor, presided. Dr. Bramwell presented an address from the Perthshire Medical Association to the guest in recognition of his services as President, and the chairman further presented him with a timepiece and purse of sovereigns. He alluded to Dr. Kew's services to the Perth Dispensary and other public institutions for upwards of forty years. Dr. Kew suitably replied.

Correspondence.

THE IMMERSION PARABOLOID.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Having perused the two letters on this subject in your last issue, I find that I must trouble you with some further observations, and set out evidence which will show the nature and extent of the priority which is due to Mr. Wenham for introducing the immersion paraboloid as an illuminator in practical microscopy.

In writing for your issue of Nov. 26, I could not refer to any communication between Dr. Beale and myself without asking his permission, which I did not then need to do. Dr. Beale has since kindly given me permission to publish his letter in any way that I may think necessary, and it is, therefore, at your service if you call for it. All that I need say, however, is that in April, 1878, Dr. Beale, having obtained a copy of my paraboloid for his own use, wrote to me asking for information as to its working, and for references to my papers on the subject. These, of course, I sent. No communication in reference to this matter has since passed between Dr. Beale and myself. With this simple statement there falls to the ground the whole structure which Mr. John Mayall, jun., has so ingeniously constructed in order to fasten upon me a charge of *mala fides*. Mr. Mayall's conduct in this matter is very natural. Ignorant of the fact that Dr. Beale's great work must have been some two years in the press, he assumes that I have acted as he would have done, and thereupon, by a simple syllogistic process, he demonstrates "my radical want of candour."

It goes without saying that no text-book on the microscope can burden itself with descriptions of impracticable or obsolete contrivances. Mr. Wenham's immersion-paraboloid has never been on sale by his own firm or any other, nor is there any optician's catalogue or English text-book on the microscope which refers either to it or to the much more fully thought out instrument which Dr. Barker subsequently failed in bringing to any practical point. Indeed, had I ever seen either Mr. Wenham's paper or that by Dr. Barker I should never have put upon Messrs. Powell and Lealand the pressure which, as an old client, I was able to do, to induce them to take the matter up.

In August, 1877, my paper appeared in the *Monthly Microscopical Journal*, and soon afterwards my friend,

Digitized by Google

Mr. Jabez Hogg, kindly sent me the reference to Mr. Wenham's paper in the old series of the "Microscopical Transactions." Having looked up this paper, I wrote Mr. Wenham an apology for not having cited his paraboloid, and asking him kindly to show me what it would do. His reply, dated August 14, 1879, runs as follows :—

"The paraboloid used with an intermedium under the slide, as well as some other contrivances for the same purpose, was described in a paper read by me before the Microscopical Society, March 25th, 1856, and was published in the "Transactions" at the time. I have sent a short note to the editor of the *Monthly Microscopical Journal* calling attention to this. Of course I have done so with courtesy, as it is simply a matter of re-invention.

"I never now go to the Royal Microspical Society, so I do not know what transpires till I see it in print, else, before your paper was published, I should have wished to have shown you the paroboloids I then made, more than twenty-one years ago."

Mr. Wenham's letter, as published [*M. M. J.*, Oct., 1877, page 206), reads as follows:—

"At the meeting on March 20, 1856, I read a paper on *illumination*, and described a small truncated parabola of crown glass used beneath the stage, on the flat top of which slides were to be laid with an intermedium of high refractive power. Animalcules, or objects in water, or other fluid were placed directly on the flat top and covered with thin glass. *Beyond making two of different sizes for my own use*, and exhibiting the effects on that occasion, *I made no fur her stir in the matter*, and it has since been twice re-invented." (The italics are mine.)

In October, 1877, I prepared and forwarded for publication in the *Monthly Microscopical Journal* a reply to Mr. Wenham's letter, and discussed critically the nature and extent of the priorities due to him and to Dr. Barker. Owing to the sudden death of the editor, my paper was, I believe, impounded by his executors. In January it was returned to me by the Secretary of the Royal Microscopical Society with an expression of regret, and the statement that it could not be published because the journal had stopped. Mr. Wenham never favoured me with an appointment to see his paraboloid, and I could not well write to him again unless he moved in the matter.

On Mr. Wenham raising the question in your columns, I again proposed that I should come and see a demonstration of what his immersion paraboloid would do, and offered to reserve the afternoon of Wednesday, the 3rd inst. for the purpose. On the 4th inst. I received a letter explaining that he had been prevented from answering my letter, and adding, "at the works I can find nothing but the original steel template of the larger size amongst my tools and traps. I have a lot of things in Essex, which will involve a day's journey to get them. I will do this, and then have comparisons made." Thus stands the matter as this issue of the journal goes to press (Dec. 9, 1879).

All the facts were perfectly known to Mr. John Mayall when, in the *Quekett Journal* for April, 1878, he wrote the footnote for me to publish, as follows :—

"As to the question of priority between Mr. Wenham and myself in the design of the immersion paraboloid, it needs only that I observe the paraboloid suggested by Mr. Wenham had not the same purpose in view as that obtained by my device; the construction was not like mine, nor was the adaptation as a piece of useful accessory apparatus in the slightest degree resembling. In fact Mr. Wenham's suggestions came to practically *nil* even in his own hands. I regard Mr. Wenham's device of twenty years ago as of no practical value—a merely empirical experiment having no definite purpose."

The last two sentences I cut out, not because in my judgment they were unsound criticism, but because I had the greatest respect for Mr. Wenham, and I would not consent to publish any sort of sneer at his paraboloid. Mr. Mayall's first statement, *i.e.*, that Mr. Wenham "had not the same purpose in view," I considered unfair. Therefore the footnote, as settled and published by me, runs as follows :—

"As between Mr. Wenham and myself, I need only to observe that the paraboloid described by Mr. Wenham was not like mine, either in its formula or its effects, and that the methods of working and applying the two instruments as accessories to the microscope do not in the least resemble each other."

Now, if Mr. Mayall's account of this footnote be correct, how came I to modify its terms in the direction that I did? Perhaps, however, I ought to throw further light upon the matter, so as to exhibit no more of what Mr. Mayall describes as "evidence of a radical want of candour."

In May, 1878, Mr. Mayall exhibited some photographs and other objects at the *conversazione* of the Royal Society. He asked my permission to allow him to include my paraboloid in his list, and he borrowed the instrument of me for the purpose, as also a large Powell and Lealand stand, with certain almost unique high-power objectives, made by Tolles, of Boston, and Powell and Lealand. Now there can be no pretence that anyone but Mr. Mayall wrote out the description of the list of objects which he exhibited, and the catalogue printed for that *conversazione* contains the words—

"New Immersion Paraboloid. Designed by Dr. James Edmunds; exhibited by Mr. John Mayall, junr."

Recollecting that, Mr. Mayall would also write descriptions of his objects for inclusion in the *Times'* report. I have taken the trouble to look out that report from the *Times* of May 4, 1878, page 13. I cite the following extract :—

"In room 2 Mr. Mayall showed some new microscope arrangements. A new rectangular prism illuminator on the immersion principle gives a wonderful definition used with immersion lenses and balsam, glycerine being spread upon the glass slide. A new immersion paraboloid, used also with glycerine or some similar substance, gives a dark field with a very sharp definition—a great advantage in protracted observations." I see that, unfortunately, Mr. Mayall's photographs did not, after all, get noticed in the *Times*, but as my name does not appear in the report, that fact is obviously not due to any intervention on my part.

In June, 1878, a difference having occurred between Mr. Mayall and myself, Mr. Mayall thought it not unbecoming to change his opinions with regard to the merits of my paraboloid, and, in consequence of some remark which he made, I wrote to *Nature* (July 11, 1878) calling attention to the priorities of Mr. Wenham and Dr. Barker, giving full references to their papers and to my own, so that microscopists might peruse the papers for themselves, and see the nature and extent of the priority which was due to these gentlemen respectively. The "candid reader" to whom Mr. Mayall appeals will see on collating the two documents that my letter to *Nature* (this volume, pages 448 and 469) in no way overrides the propositions contained in the April footnote. On those propositions I still stand, and I have never resiled from anything that I have said or written on the subject.

That Mr. Mayall himself then considered that I had not surrendered my claim is proved by the fact that in *Nature* of July 25 he wrote a further letter saying that his "attention has been directed to evidence establishing Mr. Wenham's claim," a letter which I read with vast surprise, and for which, up to this time, I have seen no justification.

Mr. Mayall is, of course, concerned at the survival and publication of a piece of manuscript which he imagined had been altered, sent to the printer, and destroyed. His attempt to fasten upon me a charge of bad faith made it necessary for me to expose his inconsistency, and it is fortunate I had preserved all the papers on this old controversy. For Mr. John Mayall, jun., whose Fellowship of the Microscopical Society dates back many years longer than mine, to pose as a deluded innocent in this matter, will only amuse those who know him and his many controversies in matters microscopical. Those who have the advantage of not knowing this dexterous gentleman will now be able to judge whether there has been any bad faith in this matter, and with whom.

The late Dr. John Barker, of Dublin, never yielded any substantial priority to Mr. Wenham. He approached the matter as a mathematician. He went to many London opticians—including Mr. Wenham's firm—but, according to his letters to me, none of the paraboloids made for him would answer. He, also writes :—"I made many mathematical trials, but found a modification of the formula $y^2 = ax$, by which most of my paraboloids were made, by Yeates, of Dublin, to be the best." Dr. Barker called upon me several times when in London, and kindly promised to send me his paraboloid, but never could "put his hand

Digitized by Google

upon it;" and his recent decease leaves me unable to say more. But being still anxious to test his paraboloid as well as Mr. Wenham's, I wrote to Mr. Yeates for a copy of the instrument, and for any information he could give. Messrs. Yeates and Son, the well-known Dublin opticians, have replied as follows, under date Dec. 3, 1879 :—

"We beg to acknowledge the receipt of your note, and, in reply, to say that we made a number of different parabolic reflectors for the late Dr. J. Barker, but as to which he considered best, or as to whether he had satisfied himself with his experiments, we can give no information."

Mr. Wenham's paper of 1856 was written in order to develope the general principles of immersion illumination, and it only incidentally refers to his truncated paraboloid. What he writes is as follows :—

"Another variation in this [immersion] principle of illuminating opaque objects is a small paraboloid of solid glass with a flat top. A black stop of the same diameter as the apex is fixed at the base of the paraboloid for the purpose of stopping out direct rays. This paraboloid is set in a ring which is screwed underneath a flat brass plate [like a small live-box inverted], so as to bring the upper plane surface of the glass exactly level with that of the plate. The parabola must be sufficiently short to prevent any rays from passing *within* the angle of total reflection relative to the flat top; or the paraboloid may be cut off at the point in the curve intersected by an angle of 45 deg. drawn from the focus." Upon the top of a paraboloid thus cut Mr. Wenham directs the slide to be placed, and he adds—"In using this instrument all that is required is to throw direct light into the parabola by means of the concave mirror."

The carelessness of this description is obvious. The parabola (a mathematical curve) and a paraboloid (a solid of revolution) are spoken of as if identical things. The "apex" of a paraboloid, being a point, can of course have no "diameter." The paraboloid was cut off somewhere—in fact anywhere—between the focus and that point above the focus where the tangent to the curve would not exceed an angle of 41 deg. (the angle of total internal reflection in crown glass) with the plane top. Upon this a film of glycerine and a slide carrying the object was to be placed, raising the object say another 1-12th inch, which, with a paraboloid so small as Mr. Wenham's, would bring the object altogether beyond the focus. Mr. Wenham gives a drawing of his truncated paraboloid, but without saying on what scale, and the drawing of his truncated lens on the opposite page is, by measurement, about eight times the real size.

Passing from the printed text and the paper drawing to "the paraboloid" itself, this instrument was, on March 12, 1879, placed by Mr. Wenham before the Royal Microscopical Society, Dr. Beale in the chair—the brass plate into which it is screwed being engraved by Mr. Wenham as follows:—"Immersion paraboloid made by F. H. Wenham, March, 1856." The radius of its plane top is about 1-7th inch. With the brass screw setting into which it is burred it weighs 5·195 grammes; of this quite half is due to the brass setting, and the lens probably weighs 35 grains. The dimensions of the lens taken approximately are :—axial length, ·3 inch; diameter of base, ·67 inch; diameter of plane top, ·3 inch.

This paraboloid thus identified by Mr. Wenham is now placed in the well-known microscopical collection of Frank Crisp, Esq., and it will always be open to the inspection of anyone who needs to examine it. Whenever the sun shines it may be tested as to its focus. An ordinary glass slide optically connected to the top of the paraboloid by a film of glycerine, and retained in position by two elastic rings, a block of uranium glass connected in the same way above the slide, and the direct rays of the sun entering the base at the normal, will at once display the position of the focus.

As to the truncated lens, in combination with a common paraboloid which Mr. Wenham is adept enough to make answer the same purpose as the immersion paraboloid, that useful device does not come into this issue.

It is to be regretted that Mr. Wenham allowed his claim to slumber until, owing to Dr. Barker's recent decease, the claim of a gentleman who spent so much effort on this subject cannot be properly represented. To Dr. Barker I have already conceded a full priority "in principle and in construction;" and although his paraboloids never came into use, that concession is due to him. Mr. Wenham's "small flat-topped paraboloid" is, in my opinion, accurately adjudicated upon by those last sentences in Mr. Mayall's draft footnote, which, in deference to so able and useful a man as Mr. Wenham, I thought it would not be becoming for me to go out of my way to publish. I submit that the evidence now published justifies the proposition that "Mr. Wenham's paraboloid was not like mine either in its formula or its effects," and that the other proposition is so obvious as not to need proof. It is upon the text of Mr. Wenham's published description that his claim depends, and this text shows that his paraboloid was never cut off below the focus, and that it was far too small to work under any slide of ordinary thickness. Mr. Wenham's charge of "plagiarism" is met by his own letter of August 14, 1877.

Various allegations made by Mr. Wenham in the last part of the third paragraph of his letter (this volume, page 491) have no foundation whatever, and his insinuating that I have some interest in advertising Messrs. Powell and Lealand can only be due to the fact that those who buy Mr. Wenham's high power objectives do not afterwards prove so grateful.

For Mr. Wenham's well-known versatility and skill at the optical lathe I have nothing but admiration and envy, and, in once more urging him to stick to his lathe, I desire only to save Mr. Wenham from ever again stooping to attack "persons of Dr. Edmunds's stamp."

Yours, &c.,

JAMES EDMUNDS, M.D., M.R.C.P., Lond.

8 Grafton Street, Piccadilly, W., Dec. 1879.

[We regret that this correspondence has become personal, and can allow it to proceed no further. To Mr. Wenham should undoubtedly be given the merit of inventing "The Immersion Paraboloid." Indeed, Dr. Edmunds does not deny the prior claim of this gentleman. What he wishes to impress upon Mr. Wenham, and those who have followed this correspondence, is of having re-invented, without a previous knowledge of the originator's idea, and put it into a more practical and workable form. We have examined the paraboloid first invented by Mr. Wenham, together with the improved apparatus known as Edmunds's Paraboloid, and are satisfied that they differ in several essential particulars. We cannot understand the angry feeling and language imported into the discussion, the use of such words as "mendacious," &c., being quite unnecessary.—ED. M. P. & C.]

PRESENTATION TO DR. BENSON, OF DUBLIN.

ON Wednesday last a most interesting ceremonial took place at the City of Dublin Hospital, when the portrait of Dr. Charles Benson, the venerable and revered honorary secretary and consulting physician to the hospital, was presented to the directors for a place in their board room, and an address to Dr. Benson himself. We are reluctantly obliged to exclude a full report of the proceedings. It is sufficient to say that the whole of the medical staff and of the board of Governors who were capable of being present attended, as well as a number of past "Baggot Street" students and many of Dr. Benson's friends and admirers, and that a most enthusiastic spirit of affectionate regard for Dr. Benson as a teacher, a colleague, a physician, and a friend, was evinced by all present. The portrait is a replica by Mr. Clarke of that which hangs in the board room of the Irish College of Surgeons, and is an excellent likeness.

Dr. Benson is, as he himself said, the sole survivor of the original co-partnership of physicians and surgeons, who founded the hospital in 1832, and since that day his relation to it has been one of honour to himself and inestimable value to the institution. It might be said with truth that he was mainly instrumental in making the hospital what it is—one of the first benevolent institutions and clinical

Digitized by Google

teaching centres of Ireland. Warm and cordial as were the expressions uttered by the speakers on the occasion, we can say that not a word spoken exceeded Dr. Benson's deserts, and we suffer the same incapacity as those who attempted to do justice to his qualities in that we feel it impossible, in the few words allotted to us, to express our esteem and respect for his professional and personal character. To have occupied a public position in our profession for half a century, and to retain it after such a period with everyone's good-will, is a lot which few share with Dr. Benson, and we can cordially join in the aspiration of the speakers on this occasion, that his years may be prolonged to enjoy the regard of his professional brethren.

A VACANCY in the staff of Jervis Street Hospital, Dublin has been declared in consequence of the resignation of Dr. Edward Wolfenden Collins, who has left Dublin and entered into practice near Sydenham. In Dr. Collins the hospital loses the services of a man of much culture and a most promising surgeon. As a student he gained the high distinctions of Medical Scholar and Senior Medical Exhibitioner in the University of Dublin, in the School of which he filled the office of Demonstrator until his departure from Dublin. It is probable, we understand, that Dr. Collins will be succeeded in the hospital by Dr. Cranny, who will bring to the institution the addition of an obstetric and gynecological department. Dr. Cranny is an M.D. and M.Ch of Trinity College, and has held the position of Assistant-Physician to the Rotundo Hospital.

WE learn with much satisfaction that Dr. Macan, Obstetric Physician to the City of Dublin Hospital, who has for some weeks past been seriously ill from typhoid fever, is at length convalescent, and it may be hoped will soon resume his professional avocations.

ANOTHER successful case of ovariotomy appears in the records of the mastership of Dr. Atthill at the Rotundo Hospital. The operation was performed on Thursday last, and, according to latest reports, the patient is convalescent.

MAJOR STUDDERT, J.P., Fort House, Kilrush, has been appointed to the important office of Poor-law Inspector under the L. G. B. for Ireland.

AMONG the recipients of honours at the distribution by Her Majesty the Queen at Windsor on Monday to the officers now in England who have served in the recent Zulu and Afghan wars, were Deputy Surgeon-General John Hendley and Surgeon-Major Charles McDonough Cuffe, both of whom received the Companionship of the Bath.

NOTICES TO CORRESPONDENTS.

CLINICAL SOCIETY.—On Friday, Dec. 12: Mr. Croft, "Analysis of 45 Cases of Excision of the Hip-joint."—Mr. R. W. Parker, "On a New Method of Excising the Hip-joint."—Mr. Pick, "A Case of Subastragaloid Dislocation."—Dr. Ledlard will show a Case of Excision of the Hip-joint in an Adult two years after the operation.

DR. CHRISTISON is thanked for his note.

DR. J. STEWART.—Yes, a remarkably good book, thoroughly reliable in practice.

F.R.C.S.—If you will send the MS. we will give it the earliest insertion possible.

POLYMORPHISM OF FEVER POISONS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In reference to the paper read by me some three weeks ago before the Medico-Chirurgical Society of Sheffield on the "Polymorphism of Fever Poisons," a short account of which is given in your issue of Nov. 26, allow me to make a slight correction. What I said in reference to typhus, typhoid, and yellow fever was this: That I looked upon epidemic and endemic yellow fever of the tropics as polymorphic forms of typhus and typhoid fevers of the temperate zones, the difference in their symptoms being dependent upon the unlike conditions of their development.

I remain, Sir, yours faithfully,
S. M. INKSTER, M.D.

DR. ALEX. STEWART, Aberdeen.—Letter to hand as we were at pres will appear in our next.

DR. YOUNG'S communication "On Bronchitis" received, and will be published when space can be had.

ERRATA.—In Dr. O'Flanagan's "Cases of Tetanus Successfully Treated," last number, a few errors appeared in consequence of the printer not waiting for author's proof, for which we offer our apologies. In line 2, for "course" read "cause;" line 25, for "stopped" read "stoppered;" line 19, page 476, for "lips" read "lip." In the paragraph commencing "Tuesday, 8 p.m.," "prevents" on line 4, should read "smarts." In last par. but one, add "was" after liniment, line 3; line 4, "ad" should be "as;" and in last par. the hyphen is misplaced, its right position being obvious.

VACANCIES.

Belmothery Union Workhouse.—Medical Officer. Salary, £90, and £10 as Consulting Sanitary Officer. Election, Dec. 15.
London Hospital.—Medical and Surgical Registrarships. Salary, £100 attached to each office. Applications to be addressed to be Secretary on or before Dec. 22.
Middlesex Hospital.—Medical and Surgical Registrarships. Applications to the Secretary-Superintendent before Dec. 20.
Nottingham Borough Lunatic Asylum.—Medical Superintendent. Salary, £450. Applications to "The Chairman of the Committee of Visitors" on or before Dec. 16.
Oughterard Union, Lettermore Dispensary.—Medical Officer. Salary, £110, with fees, and £12 as Medical Officer of Health. Election, Dec. 11.
Portumna Union Workhouse.—Medical Officer. Salary, £60, and £5 10s. as Consulting Sanitary Officer. Election, Dec. 20.
University College, London.—Professorship of Medical Jurisprudence. Applications to the Secretary up to Jan. 7.
Wolverhampton Union.—Medical Officer for the Wednesfield District. Salary, £80. Applications to the Clerk, 49 Snow Hill, Wolverhampton, before Dec. 11.

APPOINTMENTS.

ATKEY, W. T., M.R.C.S.E., L.R.C.P.L., House Surgeon to the West Sussex, East Hants, and Chichester General Infirmary.
BICKERTON, Mr. T. H., House Physician to the Royal Infirmary, Liverpool.
CAMPBELL, P. E., M.B., C.M., Junior Assistant Medical Officer to the Warwick County Lunatic Asylum.
DUIGNNAN, Dr. P. S., Medical Officer and Medical Officer of Health for the Johnstown Dispensary District of the Edenderry Union.
HALL, J. C., M.B., B.Ch. Univ. Dub., Medical Officer to the Monaghan Union Workhouse.
HARRISON, Dr. A. J., Physician to the Bristol General Hospital.
HOULGRAVE, Mr. A., House Surgeon to the Royal Infirmary, Liverpool.
JONES, A. E., M.R.C.S.E., House Surgeon to the London Hospital.
JONES, Mr. G. J., House Surgeon to the Royal Infirmary, Liverpool.
MACBRYAN, H. C., L.R.C.P.Ed., L.R.C.S.Ed., a Clinical Assistant in the West Riding Asylum.
MACINTOSH, H. W., B.A., Registrar of the Medical School, Trinity College, has been appointed to the Professorship of Zoology in the University of Dublin.
PATERSON, A. G., L.R.C.S., L.R.C.P.Ed., Senior House Surgeon to the Carlisle Dispensary, and Medical Officer to the Fever Hospital.
ROWLANDS, W., L.K.Q.C.P.I., a House Surgeon to the Royal Infirmary, Liverpool.
SYKES, Mr. R. P., House Physician to the Royal Infirmary, Liverpool.
TAYLOR, J., L.K.Q.C.P.I., L.R.C.S.I., Medical Attendant to the Royal Irish Constabulary, Tandragee, co. Armagh.
WILLETT, A., F.R.C.S.E., Surgeon to St. Bartholomew's Hospital.
WOODS, W., L.R.C.S.Ed., Medical Officer to the Monaghan Fever Hospital.

Deaths.

ADAMS.—On Dec. 1, at 22 Adelaide Street, Kingstown, of congestion of the lungs, William O'Brien Adams, M.A., M.B., F.K.Q.C.P.I., aged 72.
DURRANT.—On Dec. 4, at Eastbourne, Herbert, youngest son of C. M. Durrant, M.D., of Ipswich, aged 23.
HENDERSON.—On Nov. 28, at Pavilion Parade, Brighton, Andrew Henderson, M.D., aged about 40.
MARTIN.—On Nov. 22, at Weymouth, Dr. Edmund Glanville Martin, aged 74.
MOUNTJOY.—On Oct. 28, on the homeward passage to England, John William Mountjoy, M.R.C.S., Indian Medical Service.
ORTON.—On Nov. 29, at Narborough Hall, Leicestershire, Wm. Orton, M.R.C.S.E., aged 69.
SMITH.—On Dec. 3, at Tottenham, Charles Smith, M.R.C.S., late of Kentish Town, aged 75.
STEWART.—On Dec. 3, at 75 Eccles Street, Dublin, Henry Hutchinson Stewart, M.D., at an advanced age.
WELLS.—On Dec. 3, at Cannes, France, J. Soelberg Wells, M.D.Ed., F.R.C.S.Eng., Surgeon to the Royal London Ophthalmic Hospital.

IRISH POOR-LAW INTELLIGENCE.

THE RESPONSIBILITY FOR THE BREAKDOWN OF THE PUBLIC HEALTH SYSTEM.

In the Supplement to the *Medical Press* the week before last we published a report of the proceedings of the Boyle Guardians, which will well repay perusal by Irish sanitary officers. At the meeting to which we refer Colonel King Harman, M.P. (who, we may remind our readers, was the chief opponent of the Vaccination Act of last session), reported to the guardians his proceedings in the endeavour to induce the Local Government Board to assent to a cutting-down of the sanitary salaries in the Boyle Union. In the course of his remarks he gave expression to views strongly depreciatory of medical officers of health in general, and those of the Boyle Union in particular. The report of these proceedings having been brought to the notice of the Council of the Irish Medical Association, were considered deserving of special notice, and the following letter was addressed to Colonel King Harman.

This letter was inadvertently published in our last issue in an incorrect form, and we think it worthy of re-publication as an effective and truthful vindication the Poor-law medical officers of Ireland from the unmerited and unsustainable aspersions of Colonel King Harman :—

Royal College of Surgeons, Dublin.

Colonel King Harman, M.P., D.L.

Sir,—The attention of the Council of the Irish Medical Association has been directed to a report of the proceedings of the Boyle Board of Guardians contained in the *Roscommon Herald*, in the course of which you, as chairman, are reported to have stated in communicating the result of an interview had by you with the President of the L. G. B. for Ireland, that "the reason" the board of guardians had proposed a reduction of the salaries of their medical officers of health, was that these officers "were not doing any work for the money." You are also reported to have stated your opinion that the dispensary medical officers "cannot do the duty. It is a work that should never have been thrown on them," because they "might have to report their own patients;" and finally you are set down as having stated that "all the authorities of the L. G. B. were then called out, and they all agreed" in that opinion.

The Council of the Irish Medical Association, upon the assumption that your remarks have been correctly reported, learn with much regret that a gentleman occupying your legislative and administrative position and possessing so much personal influence, should entertain a view so prejudicial to the interests of the poor-law medical officers of Ireland, and should express those views in public, and in your official capacity, without—as the Council believe—a full knowledge of the facts. The Council, moreover, desire me to express their great surprise that the authorities of the L. G. B., if they have spoken as reported, should think it consistent with their duty to depreciate the administrative efficiency of the large and important body of medical officers who act under their control, and for whose unsatisfactory performance of duty (if such existed), the board itself would be directly responsible.

The Conncil consider it necessary, in the interests of the Poor-law medical officers of Ireland, to meet at once the statements to which I have referred with a direct and emphatic impeachment; and they propose to show, *First*, that the medical sanitary officers have always been fully competent for the efficient discharge of their duty, and anxious to be permitted to do their work honestly, and without regard to their personal interests, and—as a matter of fact—did perform their part of the sanitary duty with great energy until compelled to cease from their zeal by the hindrances and discouragements offered to them by the boards of guardians, and by the L. G. B. *Secondly*, That the decadence of the Irish Public Health System has been the natural result of the course adopted by both these authorities, and is, in no respect, chargeable against the medical officers, upon whom the guardians now propose to visit their own *laches*.

It may be well, at the outset, to remind you that the sanitary office was not sought for by the medical profession; that it was forced upon them without a question asked as to their disposition for it; and that, as a fact, the imposition of its duties was most irksome to many medical officers, and was loudly complained of; and you will probably concur that when unsought-for functions are arbitrarily put upon any class of persons, it is at least reasonable that they should be liberally remunerated. The first step, however, in the series which has now culminated in the second breakdown of the Public Health System, was the order issued by the L. G. B. to the sanitary authorities not to pay to any dispensary medical officer for sanitary duty more than one-fourth of his dispensary salary, a suggestion of which those authorities availed themselves by voting remuneration, which the Council can only characterise as ridiculous. The average salary of all the medical officers of health in Ireland in 1876, two years after the passing of the Act, was under £18 a-year for the performance of duties analogous to those for which English medical health officers received a much larger sum. But this refusal of reasonable payments was not the only discouragement with which the medical officers of health had to contend, for they were met, as a general rule, with the open or covert hostility of the sanitary authorities who had been trusted by Parliament to promote sanitation, and by the coldness of the L. G. B. to all their complaints. Their reports and suggestions as to sanitary

Digitized by Google

improvements, drawn up at much trouble and after unpleasant inspections, were, in a great majority of instances, wholly disregarded, marked "read," or indefinitely postponed, while the L. G. B., in consequence of its own refusal to provide inspectorial sanitary supervision, was completely in the dark as to the existence of the nuisances in question, and the attitude of the individual Sanitary Authority respecting those nuisances, and, therefore, was unable and unwilling to aid the medical officer in his efforts for improvement. The complaints and remonstrances of many of the medical officers of health, then and since, found their expression in the quarterly returns made by them to the Registrar-General, from which excerpts are regularly published, and you will there find abundant proof that medical officers were not backward in bringing the shortcomings of the public health system and the deplorable sanitary state of Ireland under official notice, although the great majority of such officers did not feel it their duty to express their views on the subject to any department other than the sanitary authority. If those representations were, as they unquestionably were, utterly ignored by the L. G. B. and the Sanitary Authorities, the fault lies with those bodies. If, under these circumstances, the activity of the medical officers was relaxed, who is to blame? That these officers are not responsible, that in spite of all impediments they did their duty cheerfully and zealously, is proved beyond doubt by the Parliamentary return made on the motion of Dr. O'Leary, M.P., on the 21st of March, 1878, by reference to which you will find that, in the first year of the operation of the Act of 1874, the medical officers made nearly 26,000 reports, or 32 reports per man. In the next year there was, in consequence of the way these reports were treated, a falling off of 56 per cent. in the number, which dropped to about 11,000, or 14 reports per man, and, in the third year, from similar causes, a further reduction to 9,000, or 11 reports per man. It should be remembered that the number of reports bears no proportion to the sanitary work done, inasmuch as all medical officers effect their object as much as possible by remonstrance and threats, and do not report the nuisances to the guardians until they cannot help doing so.

The Council have thus endeavoured to show the injustice and inaccuracy of your statement that the sanitary medical officers were not "doing any work for the money," and "could not do the work," in which view it is said the L. G. B. concurs. In conclusion, they desire to point out that the course now proposed by the Boyle guardians and other sanitary authorities can have but one effect, *i.e.*, to make the sanitary organisation of Ireland less and less efficient, and the public health of the country worse and worse. No employer of labour in any walk of life can get more work than he pays for, and it may be safely assumed that the less the medical officers are paid the less energy they will expend on their duties, and the greater the proportion of the work which will remain undone. If it be ever really desired that the sanitation of Ireland shall be improved, it can readily be done. Let the L. G. B. provide itself with the means (which it has never pretended to possess) of knowing which sanitary authorities and which medical officers are honestly doing their duty. Those means this Association has, in vain, exercised all its influence to procure, while the Government has resisted every such proposition. When such proper and essential supervision is provided, then let the medical officers of health be impelled to energetic action by the L. G. B., *and be paid what is reasonable and fair, and no more*, for their work, and let the Sanitary Authorities be so stimulated to work, and held accountable for disregard of their part of the duty.

If this be ever done, and if afterwards, it appears that the medical officers cannot or will not work, they will then, and not until then, deserve to be held responsible for failure.

I am, Sir, yours obediently,
JOHN WILLIAM MOORE, M.D., Secretary of Council of Irish Medical Association.

THE SUPPLY OF DRUGS TO IRISH UNIONS.

WITH a choice among 649 preparations of drugs offered by the schedule requisitions for medicines prepared by the Local Government Board, it may seem extraordinary for us to suggest that it would be possible to prepare something which would be more practically adapted to the wants of dispensary and poor-house medical officers.

Those, however, who are acquainted with the schedule, are well aware that it has been prepared by some one who was totally unacquainted with the practical details of dispensary work. It is simply an abstract of the Pharmacopœia, and contains every crude drug which can be required for the preparation of medicines into the usual forms in which they are dispensed—colchicum bulbs and seed, squill bulbs, fluid mercury, ipecacuan root, guaiac wood, &c., &c.—everything is offered in its most elementary form, as well as in its prepared condition, as if dispensaries were to be converted into manufacturing drug mills. Yet all this useless material has to be priced and tendered for from year to year in every union throughout Ireland. Nor is it merely useless trouble which is given by this senseless arrangement. It opens a wide door to contractors to "cook" their tenders. One of these for the year 1878 lies before us at present, and here are some of the prices:—Rhubarb, no quality being specified, is 8d. per lb., the powder 2s.; quina is 4s. an oz.; quina disulph., 4s. 6d.; quina sulph., 11s.; opium is offered at 15s. per lb., opium powder at 30s.; tincture of opium is 2s. 8d., or about 3d. less than the price of the opium and spirit required to make it; pulv. opii. comp. is 2s. 10d. per lb., or 2d. less than the price of the opium powder which ought to be in it, not to mention the ipecacuan powder and sulphate of potash. The prices of the last four articles in the list of a high-class wholesale house are as follows: 23s., 32s., 4s. 6d., and 6s. 6d. It is very evident from these figures that the tenders are arranged with a purpose, and that purpose is to put a low price on articles not likely to be required, and a high one on those which are, unless the article be one which, like laudanum, admits of being easily reduced in strength. It is notorious that drugs of inferior quality are supplied to Irish Unions, but who is to expose the adulteration? The medical officers are supposed to report to their Dispensary Committees if the drugs supplied are not of good quality. But analysis of drugs is no part of the duty of a medical officer, and, besides, if he does complain of the drugs supplied, he is liable to an action at law by the contractor if he should fail to substantiate his charge. There is practically no check on the quality of the drugs supplied.

But besides all this, many of the preparations of the Pharmacopœia are in a condition unsuitable either for keeping or dispensing. Pill masses and powders spoil from damp, and it is tedious and troublesome to divide them into suitable doses. Infusions and decoctions take some hours to make, and when made do not keep.

Modern improvement has removed these difficulties. All important medicines can be made up in pearl-coated pills, in great variety of doses and combination, and concentrated infusions and decoctions can be had which keep, and which are ready for use if diluted with seven times their bulk of water. These preparations may be relied on for their excellence if got direct, or in bottles closed by

Digitized by Google

their trade mark, from manufacturers of known character and standing. It would put the dispensaries of Ireland in a very different position of efficiency if they were furnished with a well-selected supply of these pills and concentrated infusions.

The easiest way to attain this would be to revise the tender list, and strike out of it everything that is only required for the drug manufactory. A space should be left for specialities, and the medical men of each union should supply a list of the articles for ready dispensing which they require, and the name of the manufacturer from whom they wish them to be got. These can be offered for contract with the other articles in the list, and when the supplies are sent in the medical officer can see that he gets his supply under the trade mark of the manufacturer he has specified. By this arrangement the system of purchase by contract would not be interfered with, while the medical officer could always assure himself of the goodness of the article.

This plan is so simple that we commend it to the attention of the Local Government Board. It is not very creditable to the government of that body that the scandalous condition of the supply of medicines to Irish Unions should be perpetuated from year to year, merely because their pet scheme of a central drug manufacturing establishment under their control was knocked on the head.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF NOVEMBER, 1879.

NOVEMBER 3rd.—Duigenan, Patrick Samuel; Wellington Lodge, Trim, co. Meath; Lic. R. Coll. Surg. Irel. 1879, Lic. R. Coll. Phys. Edin. 1879.

7th.—Newburgh, Thomas; Beach Cottage, Bantry, co. Cork; Lic. R. Coll. Phys. Edin. 1879, Lic. R. Coll. Surg. Edin. 1879.

10th.—Ashe, William Cunningham; 4 Leeson Park, Dublin; Lic. R. Coll. Surg. Irel. 1879.

12th.—Wolseley, William Owen; 2 Montague Terrace, Higher Broughton, Manchester; Lic. 1879 and Lic. Mid. 1879 K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel. 1879.

14th.—Esmonde-White, Henry Laurence; Plymouth, Devon; Lic. 1879 and Lic. Mid. 1879 K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel. 1878.

15th.—McCaw, John, Dromore, co. Down; Lic. R. Coll. Phys. Edin. 1879, Lic. R. Coll Surg. Edin. 1879.

15th.—Smythe, George Frederick Alexander; Aldershot, Hants; Lic. R. Coll. Phys. Edin. 1879, Lic. R. Coll. Surg. Irel. 1879.

18th.—Crimmin, John; Bruff, co. Limerick; Lic. R. Coll. Surg. Irel. 1879.

18th.—Porter, Robert; Mullaney, Burt, Londonderry; M.B. 1879 and M.Ch. 1879 Univ. Glas.

18th.—Strahan, Samuel Alexander Kenny; Greenmount Road, Belfast; M.D. 1879 and M.Ch. 1879 Q. Univ. Irel.

21st.—Dwyer, Henry Hamilton; Narborough Road, Leicester; Lic. R. Coll. Surg. Irel. 1879.

21st.—Lane, John Ebenezer; Sandbach, Cheshire; M.D. Q. Univ. Irel. 1879.

21st.—Cullin, Richard Blair; 10 Richmond Place North, Dublin; Lic. R. Coll. Phys. Edin. 1879, Lic. R. Coll. Surg. Edin. 1879.

22nd.—Maguire, Patrick; Arney, co. Fermanagh; Lic. R. Coll. Surg. Irel. 1879.

24th.—Bolster, James McMullen; Mallow, co. Cork; Lic. R. Coll. Phys. Edin. 1879, Lic. R. Coll. Surg. Edin. 1879.

25th.—O'Connor, Arthur Patrick; 5 Russell Place, Dublin; Lic. 1879 and Lic. Mid. 1879 K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel. 1879.

25th.—Walsh, Thomas Pakenham; Enniskillen, co. Fermanagh; Lic. R. Coll. Phys. Edin. 1879, Lic. R. Coll. Surg. Edin. 1879.

26th.—Doyle, Francis Joseph; 11 Mountjoy Square, Dublin; Lic. 1879 and Lic. Mid. 1879 K. Q. Coll. Phys. Irel., Lic. R. Coll. Surg. Irel. 1879.

26th.—Hanly, Edward; The Elms, Collegiate Crescent, Sheffield, Yorks; M.D. 1879 and M.Ch. 1879 Q. Univ. Irel.

27th.—Williams, David Leopold; Dungarvan, co. Waterford; M.D. 1879 and M.Ch. 1879 Q. Univ. Irel.

27th.—Leonard, John; 4 Grattan Parade, Drumcondra, co. Dublin; Lic. R. Coll. Phys. Edin. 1879, Lic. R. Coll. Surg. Edin. 1879.

29th.—Allport, Henry Kingston; 43 Patrick Street, Cork; M.D. 1879 and M.Ch. 1879 Q. Univ. Irel.

10th.—Morrissy, Edward; Navan, co. Meath; Lic. R. Coll. Surg. Irel. 1878; Lic. K. Q. Coll. Phys. Irel. 1879.

28th.—McMorran, Robert; 1 Richmond Place North, Dublin; M.B. 1868 and M.D. 1868 Univ. Dub.

28th.—Croly, Arthur England Johnson; Greenfield, Rathfarnham, co. Dublin; Lic. R. Coll. Surg. Irel. 1879, Lic. 1879, and Lic. Mid. 1879 K. Q. Coll. Phys. Irel.

MEMORANDUM.

The following names have been erased from the Register of the Branch Medical Council, Ireland, during the month of November, 1879, pursuant to the 14th section of the Medical Act, no reply having been received to several letters of application, viz.:—

Sweeny, Austin; Ennistimon, co. Clare.
Stevenson, James; 20 Coleraine Street, Dublin.
Warren, Robert Thomas; Barnabaly Cottage, Ringskiddy, co. Cork.
Wilson, Stewart; Omagh, co. Tyrone.
Weir, Marshall; Dromore, co. Down.
Williams, James E.; Army Medical Staff.
Wilkin, Thomas Henry; Tynemouth, Sunderland.
Vance, John; 3 Merrion Square North, Dublin.
Woodroffe, Richard; 3 Terenure Road, Rathgar, co. Dublin.
Divers, Edward; Queen's College, Galway.
Knox, James; Walshestown, Balbriggan, co. Dublin.

CARRICK-ON-SHANNON UNION.

THE previous board requested a written explanation from Dr. Kiernan in reference to a letter sent in, from which the following is extracted:—

I beg to submit the following facts:—I met Dr. Kiernan and he informed me that three of Morris's children were ill of fever, and that his daughter would call on me the following morning for an order of admission to union hospital. I went to the house. When I arrived there Morris told me some of them were weak, and that another of them became ill that day. I then said that I would make arrangements with the master about sending the van and covering for their removal. The master would not send it without a medical certificate. I then applied to Dr. Kiernan for a certificate, he having visited them as dispensary patients. He refused to give one, saying they are fit. I told him that would not do, that I could not have them removed without a written certificate. He again refused to give one, remarking, "I suppose if anything would occur I would be held responsible." Being anxious to have the children removed, I reported the matter to Mr. Whyte, D.V.C., and he sent me to the master with an order. When they were removed the elder boy of sixteen years fainted. I decided not to remove him until the doctor would examine him, he not having been visited by the doctor for the previous two days, I called in the services of Dr. Bradshaw.

JOSEPH HILL, R.O.

Read the following from Dr. Kiernan:—

GENTLEMEN,—In reference to the case of fever I have to state that I received at 2 o'clock p.m. a ticket to visit O. Morris. I went to the house and found them in the incipient stages of fever. I recommended that they be removed to the union hospital. The mother assented. Having told her what to do, and that to convenience her

Digitized by Google

I would call at the residence of the relieving officer and arrange with him for their removal, I went there immediately. On my return home I met the relieving officer on the public road, and having no materials for writing a certifi te, I told him of the children, and advised their mother to send her daughter to him to have them removed next morning. I heard no more from him of them for twenty-five hours, after which time he came to me and asked for a certificate for the Morrisses. I asked are they not in hospital. He replied no. I said more than twenty-four hours elapsed since I visited them. He told me the workhouse master would give the van, but that the man was not able to take the children to the van—the relieving officer would have to do it, and he declined. The van having been offered, I did not consider that I could compel by any certificate of mine either the relieving officer or driver of the van to act. I told relieving officer I considered the children fit to be removed, and if I had a conveyance I would give it to take them. He then left. I was only prevented giving further attention to the children by the impression that they should be and were removed to the hospital.

Chairman—We asked Dr. Kiernan for an explanation, and he has given one. It appears the medical officer is bound to grant a written certificate on every occasion when demanded by the relieving officer. He did not do so, and the consequence was the children were left at their home without medical attendance for a day and a night.

Mr. Kirkwood—I merely asked the question if we would take any action, because it is a curious thing we should pay a doctor and he does not see his business is performed.

Mr. Begg—Sure he did visit the man, and when he met the relieving officer he had no materials for writing. Whether it was the doctor's duty to sign a written certificate to the relieving officer or not, I don't know.

Mr. Bournes—It is beyond all question he is bound to give a written certificate. I may state that the master would not take the relieving officer's verbal order for the van, nor is he called on to do so.

The Chairman quoted the section of the Act showing the doctor was bound to give a written certificate, and his explanation was not satisfactory at all. If he had no writing materials on the road, he had them when the relieving officer called at his house. No one could understand the second last sentence of his letter.

The matter was referred to the Local Government Board.

MONAGHAN GUARDIANS.

A MEETING was held for the purpose of electing a medical officer to the Workhouse, in the room of Dr. Ross, resigned. There were three candidates—Dr. Hall of Scotstown Dispensary, Dr. Adams, and Dr. Reed.

The votes were then taken as follows :—

For Dr. Hall—20 ;

For Dr. Adams—10 ;

For Dr. Reed—9.

Mr. John Woods (Monaghan) demanded a second poll on behalf of Dr. Adams.

Mr. James Mitchell (Clerk of the Union) said he wished on behalf of Dr. Adams to withdraw his name.

However, Dr. Adam's friends insisted on a poll, which, when taken, the voting stood as follows :—

For Dr. Hall—21 ;

For Dr. Adams—17.

LIMERICK UNION.

CAHIRCONLISH DISPENSARY.

MR. J. G. BARRY brought before the Board a communication from the Cahirconlish Dispensary committee in reference to the purchase of a residence and dispensary for the medical officer of the district. He said that about ten or twelve years ago, when a medical officer was appointed for that district, it was made compulsory upon the gentleman appointed to reside in the village, as his predecessor had not resided there, and great inconvenience was caused to the people thereby. There being no available residence, after a time he obtained a site for one from the owner of the soil, Mr. Gabbett, upon which he built one at an expense of about £1,200. But after a time he left, having obtained a better dispensary district and the present medical officer was appointed upon the same conditions as his predecessor, and he had no residence, so he had to rent the one which his predecessor built. Now the house in question was about to be sold by the owner, who laid out £1,200 upon its erection on an acre of land, and rented at 30s. a year upon a lease for ever. There was an Act of Parliament giving power to Boards of Guardians for the purchasing or building of houses for dispensaries and residences for dispensary medical officers. If the Board, under the terms of the Act, purchased the house in question, they would save the rent of a dispensary, which they could add to the house, or convert part of it into a dispensary. They could borrow the money through the Board of Works from the Treasury, and the rent they would charge the doctor would pay the greater part of the interest on the borrowed money. They could borrow the money at five per cent. The £25 a-year would pay three per cent. on the money, and the Board, or rather the divisions comprising the dispensary district, would have to pay the remaining two per cent.

Mr. Studdert—The loan is terminable.

Mr. Barry replied that of course it would be terminable, repaid in thirty years, and then they would have the place rent free. There were three classes of people for whom the Act contemplated the erection of houses, and who required residences—the priest, the dispensary doctor, and the schoolmaster.

The Chairman said it was altogether a matter for the Cahirconlish Dispensary Committee, who would have to pay the money, and he suggested to refer the matter back to them with power to act.

Mr. Meehan recommended the Board to wait for next year, when money could be borrowed from the Board of Works at three and a-half per cent., repayable in fifty years.

The Chairman's suggestion was agreed to.

BURIALS.

BY orders published in Tuesday night's *Dublin Gazette*, with respect to the burial grounds situate in the North Dublin, South Dublin, and Rathdown Unions, the clerk, or secretary, or registrar to every burial board and cemetery company or other authority having charge of any such burial ground as aforesaid, shall make to the Registrar-General of Births and Deaths in Ireland, and with respect to the burial ground in the unions mentioned below, the clerk, secretary, or registrar shall make to the registrar of deaths of the district a return weekly regarding the persons whose bodies have been interred in such burial grounds, and shall be paid by the sanitary authority of the district at the rate of threepence for each separate entry of the required particulars.

TO READERS.

THE Editor will feel especially obliged by receiving copies of newspapers which contain any Poor-law or other intelligence of medical interest, in order that he may, if fit, republish it for the benefit of the readers of the *Medical Press*. Although twenty-one of the leading Irish newspapers are received at the Irish office, many things may escape notice which are deserving of attention. Newspapers should be marked, and addressed to Dr. JACOB, at the Dublin office of this paper.

DIPHTHERIA.

By W. H. DAY, M.D.,
Physician to the Samaritan Hospital for Women and Children.

(*Continued from page 496.*)

THE paralysis following diphtheria is generally curable, and yields to treatment in time. The cases met with are frequently like the one in question, the paralytic symptoms being most severe on that side of the body which corresponds to the severity of the throat disorder. Here the left side of the throat was most affected, and the soft palate, cheeks, and limbs of the same side were also implicated. The paralysis of the lower limbs, according to Trousseau, takes place before the upper extremities, a fact which has not been observed by Dr. Greenhow. The affection appears to bear some resemblance to loco-motor ataxy, but galvanism, which is of no use in this disorder, has considerable power over diphtheritic paralysis.

Paralysis of the lower limbs, and wasting of the extremities, occur in some cases, while paralysis of the upper extremities more rarely happens. Where the muscles of respiration are affected danger is imminent.

The sight is sometimes impaired by diphtheria, as I have pointed out, but the weakness of vision, resulting from paralysis of the ciliary muscles passes off when the health is restored. Loss of taste and smell also occur. Deafness is another consequence of the disease. According to the experience of Dr. Maund, "the frequency of these paralytic affections is in inverse ratio to the severity of the attack of diphtheria." . . . . . out of two hundred cases attended in East Kent in 1858 and 1859, not more than ten exhibited any secondary nervous symptoms. (*a*)

Bronchitis and broncho-pneumonia are common complications of diphtheria, as they are of measles and smallpox.

Albuminuria is one of the most interesting features of the disease. Attention was first drawn to this symptom by Dr. Wade, of Birmingham. (*a*) It generally appears at an early period of the disease. It is a frequent complication of diphtheria, and increases the danger to life. Whether albumen is present in large or in all small quantity, it is a serious symptom. But albumen bears no relation to the other symptoms, as it is equally present in mild as in severe cases. Casts of the urinary tubes do not invariably accompany the most profuse albuminuria (*b*), and the albumen may disappear altogether in the course of a few days, as the approach of convalescence is reached. Greenhow remarks that he has "several times been unable to detect albumen by the proper tests in very malignant cases of diphtheria." (*c*)

Hæmorrhage from the nose and bronchial mucous membrane occurs occasionally in conjunction with diphtheria, and eruptions of the skin resembling typhoid fever and measles are also mentioned by different observers. Erythema, urticaria, and dark claret spots like purpura have also been noticed.

Morbid Anatomy.—On examining the bodies of children and adults who have died of diphtheria, evidences of bronchitis and pneumonia are frequently seen. In the trachea and bronchial tubes the peculiar membranous formation is found, and on the removal of the exudation the mucous membrane is seen congested and excoriated, and there are small bloody points similar to those observed in the faucés. As the disease descends into the larynx and trachea, the false membrane becomes thin, and spread out like a transparent film, or the exudation is converted into a thick creamy fluid, as may be observed in some cases of genuine croup. The false membrane has been found lining the bronchial tubes to the third or

Digitized by Google

fourth bifurcation. It sometimes extends to the œsophagus and stomach, which are found red and covered with exudation. The mucous membrane may be thickened or ulcerated, and the tonsils gangrenous.

The heart has been found small, and its muscular tissue pale; cases, too, of fatty degeneration have been recorded, and the parietes have been studded with black infiltrated patches, and petechial spots from sanguineous extravasation. Fibrinous coagula sometimes occur in the cavities of the heart, as in scarlet fever and the pneumonia of children. They may be seen in the right auricle or ventricle, or in all the four chambers of the heart, of firm consistence, and so adherent to the chordæ tendineæ, that the deposit must have happened during life.

The kidneys have been found quite healthy after death, as may be expected when the urine has been free from albumen during life. They are sometimes congested in simple cases, and where albumen has been a persistent symptom the microscope has revealed fibrinous casts of the tubes, with granules of hæmatine and blood corpuscles.

The sinuses and membranes of the brain and venous system generally have been found remarkably full of blood; and in a fatal case recorded by Sir William Gull, and quoted by Dr. Greenhow, the membranes of the brain and spinal cord were in a state of suppurative inflammation. (*a*)

Diagnosis.—The diagnosis of diphtheria from croup is given in the chapter under the latter heading.

I may here quote an interesting passage from Niemeyer on the anatomical appearance of the exudation when the disease has invaded the larynx and trachea. "If the larynx and trachea participate in the disease, the croupous, not the diphtheritic, form of inflammation of the mucous membrane occurs—that is, the surface of the mucous membrane is covered with a more or less tough and consistent false membrane, which may readily be removed, and leaves no loss of substance after its removal. This circumstance has induced some physicians to identify primary genuine croup, which is due to catching cold, &c., with croupous laryngitis caused by infection with diphtheritic contagion. I consider this a false view. The division of diseases, according to the pathologico-anatomical changes they induce, is only a make-shift. In all cases where, as in genuine and diphtheritic croup, we find that two anatomically similar disturbances of nutrition depend on very different causes, we should consider them as distinct." (*b*) It is this similarity in the character of the exudation between inflammatory croup and diphtheria which has continually led observers to consider them as one and the same disease; but this certainly cannot decide the question.

The throat in malignant scarlet fever and diphtheria is very much the same in appearance, and a mistake may readily be made in attempting to ascertain the source of origin. As regards the diagnosis at the beginning of diphtheria, the more circumscribed redness and the peculiar yellow patch of the exudation is, from an anatomical point of view, so characteristic that it is conclusive evidence of the disease. Yellowish or greyish-brown sloughs of plastic lymph on the tonsils and pharynx, later on leaving a bleeding surface where the membrane is removed, are common in diphtheria; but in severe instances of either disease ashy looking gangrenous deposits may be seen, and from this point of view a diagnosis would be impossible. In scarlatina the constitutional symptoms preceding the throat affection are more marked, the skin is pungent and hot, and the temperature is high, whereas in diphtheria the throat may be severely affected, whilst these symptoms are not present, and the pulse and respiration are low. In both diseases the lymphatic glands are involved. The throat generally presents a more uniform redness, and the tongue is characteristic in scarlet fever. The soft palate and tonsils present a milky or cream-like aspect; there is a thick layer, which soon clears off, leaving the parts beneath angry and red. In diphtheria the exudation is more deeply seated, and it comes off in dense membranous layers, representing a cast of the surface on which they have formed.

At a very early stage it is not easy to distinguish the redness of diphtheria from the inflamed sore throat of inflammatory catarrh, for there the tonsils are tumid, and have a thin layer of lymph upon them. The pharynx is vascular and irritable, and the lymphatic glands are tender and enlarged; but they go down when the cold is relieved. I am bound to admit that in healthy subjects an inflamed state of the cervical glands is exceptional in cases of tonsillitis. I have many times known children with a temperature of 103° or more in this complaint, and the throat so swollen and the fauces narrowed that the swallowing of liquids was most painful, and yet the glands in the neck were not enlarged. When they are swollen there is fear of a strumous taint, and the specific inflammation is often sufficient to excite chronic enlargement, if not suppuration of these glands. Then there is a discharge from the nose, and the fever is considerable, with thirst and difficulty in swallowing.

The diagnosis from tonsillitis can generally be made; the constitutional symptoms are not of the low and adynamic type which belong to diphtheria, and one tonsil is more affected than the other.

Scarlet fever and diphtheria have prevailed altogether the same time and places, and each disease has exhibited the characteristic local symptoms. One member of a family has had the peculiar exudation of the fauces, but no rash or desquamation which occurs in scarlet fever. "Sometimes," says Dr. Greenhow, (*a*) "cases of diphtheria and scarlet fever have even been intermingled in the same family, or diphtheria has appeared in persons who have been in communication with patients suffering from scarlet fever."

Another difference between the two diseases is that the albuminuria of scarlet fever comes on at a late stage, often at the end of a week or month after the eruption has left, during the period of desquamation, and it goes on to dropsy and anasarca, with hæmaturia. In diphtheria, albuminuria is an earlier symptom when it does occur; hæmaturia is rare, and dropsy does not result, nor is the excretion of urea lessened. The urine does not present the smoky appearance which is common in scarlet fever, but casts of the urinary tubules are generally found. (*b*) The presence of albumen in the urine is by no means a constant symptom, even in severe cases, but when it is present in large quantity it is a serious indication. Anasarca is rarely present except in cases complicated with scarlet fever. Uræmia has not been observed in connection with the albuminuria of diphtheria; but excess of phosphates and urates, with high specific gravity of the urine is of common occurrence. (*c*)

It has been asked whether there is any relationship between diphtheria and enteric fever, and it appears certain that the two diseases are not unfrequently associated. Dr. Murchison considers that it is not true diphtheria, the throat complication in enteric fever being frequently found where there is no diphtheria. As the causes of the two diseases are much alike, we should expect them to prevail together, and not look upon their existence as a mere coincidence. Dr. Greenfield brought before the Pathological Society (Nov. 6, 1877) a specimen of diphtheritic membrane from the larynx and pharynx of a child, æt. 5, who had been under the care of Dr. Murchison at St. Thomas's Hospital, suffering from unmistakeable enteric fever. There was ulceration of Peyer's patches, and also swelling and round excavated sloughing ulcers in the lower part of the ileum. In addition there was broncho-

pneumonia, but no false membrane could be seen on the fauces, or the tonsils, which were red and swollen.

As to the communicability of the disease, it is held to take place through the secretions of the throat by Bretonneau and others; but the experience of many medical men during the recent epidemic, does not concur in the opinion that the disease is communicated in this way. (*a*) In contemplating the record of cases, however, we can hardly fail to observe that the diphtheritic secretions have induced ophthalmia and throat affections in those persons who have been nursing the sick, or seized upon the medical attendants who have been close enough to receive particles of the exudation when the patients have coughed or sneezed during an examination of the throat and fauces, or the application of some local agent. The local character of the disease so induced has been, in a few instances that have come within my knowledge, so precisely like the diphtheritic exudation, that I think the evidence of propagation by contact with the secretion cannot be set aside. The disease has spread with rapidity in the cottages of the poor, where the appliances of the sick are scanty, and cleanliness is disregarded. Then, again, a child labouring under diphtheria has been brought from a distance to its own home, and soon afterwards the disease has attacked other members of the family, when previously to its return not a single case had happened in the house, or the surrounding district for many miles. Dr. Squire notices that the more abundant the secretion in particular cases of diphtheria, the greater the danger of infection. (*b*)

I think we shall be forced to admit that diphtheria, like typhoid fever, has sometimes a spontaneous origin, when soil and season, temperature, filth and uncleanliness combine to lower the general health, and contaminate the blood. If it were not so, how shall we explain the alarming outbreaks of these diseases in schools and isolated homes, and their tendency to remain within a limited area, and not to spread in an epidemic form?

The infection of the atmosphere by the exhaled air of the sick patient, leaves no room for doubt that this is another mode by which the disease is propagated. Children who have been in the same house with diphtheritic patients have contracted the disease, when they have not ventured near the sufferer, and there are no doubt other vehicles for the transmission of the poison, subtle, tenacious, mysterious, ever ready to seize upon the young. "The greater frequency of the disease among children than adults does not seem to me due to greater predisposition of the former, but to their being more exposed to infection than adults are." (*c*)

(To be continued.)

ON A SUCCESSFUL CASE OF TREPHINING OF THE SKULL. (*d*)

By WILLIAM THOMSON, F.R.C.S.,

Surgeon to the Richmond Hospital, Dublin.

On the 13th of last May I was hurriedly called to the hospital to see a little girl aged five years, who had just been admitted. She had been playing about the stairs, and had fallen upon her head to the hall below, a distance of 12 feet. She was picked up, somewhat stunned, but she recovered consciousness speedily. Only a short time elapsed, however, until she became convulsed on the left side, and she was brought to the hospital. When I saw her she was lying in a semi-unconscious state, the whole of the left side twitching. The side of the face, the mouth, the left arm and leg, were jerking, almost without intermission. The pupils were widely dilated, and the pulse was slow. On the right side, somewhat below the parietal eminence, was a scalp tumour, but without any wound, and I thought I could detect a line of depression running antero-posteriorly under it. I believed that a fracture of the skull had taken place in this region, and I accordingly had my colleagues summoned at once. Before they arrived, however, a more decided change had taken place in the patient. The convulsions had ceased, and were succeeded by complete hemiplegia of the left side, and complete unconsciousness had followed. With the concurrence of my colleagues I proceeded to divide the scalp tumour so as to expose the parts beneath. I made a single free incision from a point corresponding to the meeting of the upper and posterior margins of the right ear upwards to the parietal eminence. The periosteum was divided in the same line, and at once a linear fracture was revealed, running from before backwards, at right angles to the line of incision, and intersecting it at about the middle point. The soft parts were carefully retracted, but the line of fracture reached beyond the portions of bone that I could expose. There was no appreciable depression, but through the fissure blood flowed very freely, and the struggles of the patient, who up to this had been insensible, showed that some relief was already given. I determined, however, to go further, and I applied a medium-sized trephine. A circular piece of bone, which included part of the fracture, was removed. The blood flowed freely for a few moments and then ceased. A small clot was revealed, and taken away. Then I passed a probe between the bone and the dura mater for some distance round the opening, removing several other small clots.

The parts had now been cleaned of all substance likely to produce pressure, and we had the great gratification of seeing our diagnosis and our treatment justified. The little patient was crying lustily; her consciousness was almost complete, and there was an attempt to move the hand. The question, however, still presented itself, had we got at the whole cause of the symptoms. The dura mater bulged into the opening in the bone, and was rather blue, and a suspicion existed that the hæmorrhage was not confined to the outer surface of the dura mater, but that it was beneath it as well. Ought we to take the serious step of making a deeper incision, to give exit to a supposed collection of blood farther in. We discussed this point, and agreed to postpone action until we saw the result of what we had already done. In two hours I again visited the child, and I was greatly relieved to find that the urgent symptoms had vanished, that the paralysis was gone, and that she was able to shake hands and to answer intelligently any questions put to her.

The next day her pulse was 130, her temperature 99° F. She had half-grain doses of calomel every fourth hour for a couple of days, and never developed a single symptom to cause alarm. There is no special remark to make on her treatment. She was given very light, nutritious food, and was kept in a quiet room, and in three weeks was able to leave bed. In a month she left hospital, quite well. I have had an opportunity of seeing her on two occasions since. The external wound is perfectly healed, but the opening in the cranium does not seem to have filled to any great extent. Her health is excellent.

The case is of interest because of its rarity and success, and because of the questions of diagnosis and treatment that are involved. The occurrence of unilateral convulsions is not a proof in itself of compression. They may occur in brain bruising, or in simple concussion, and they may therefore be regarded as indicating some irritation rather than serious compression. Sir Benjamin Brodie has noticed this circumstance, and says:—"I have not observed convulsions take place where there are symptoms indicating the existence of considerable pressure on the brain. The pressure in these cases does not destroy the function of the brain; it seems to act merely as a cause of irritation, and the operation of it may be com-

Digitized by Google

pared to that of an exostosis, or other tumour in fits of epilepsy." But here there was not any room for doubt, for pressure effects were quickly developed. Paralysis followed the convulsions on the left side, and as there was a distinct scalp tumour on the right, the situation of the primary injury was, we believed, pointed out. Paralysis, it is well to bear in mind, as Hutchinson observes, may result from arachnitis, without any distinct pressure; but here there was no time for any such inflammatory change. That the pressure was not in any degree due to bone, was clear from the history. There was an interval of recovery after the accident, there were convulsions, next followed hemiplegia, pointing to a pressure force slowly increasing and caused by the gradual outpouring of blood.

But now having satisfactorily read the symptoms we had to deal with, there came the important subject of treatment. Were we justified at all in proceeding to the extreme measure of trephining? If the mischief proved to be beyond reach we should only have added a new risk to the child's life by converting a simple fracture into a compound one with its increased chances of inflammation of the brain and its membranes. Moreover, objection has been made to such an operation in children, because of a supposed tolerance they have of brain injuries, and because, in cases such as I refer to, the blood extravasation may be small, and the patient may recover.

But however tolerant the infant brain may be of injury, there must always be a limit, and the danger of adopting an expectant instead of an active treatment, where that is possible, lies in the fact that we cannot determine that limit. The line is infinitely variable. We read of men recovering from fearful brain injuries; yet we see every day cases where they die from a comparatively slight concussion or contusion. Neither is there any means of determining the extent to which an extravasation may go. It may be quite small, it is true, but it may go on until the brain is squeezed out of shape by the clot, and its functions are fatally impaired. Quiescent surgery is often admirable, but it at times leads to nothing better than the acquisition of a museum specimen.

Mr. Prescott Hewitt, in "Holmes' System of Surgery," mentions some interesting cases. In St. George's Hospital, a patient of Mr. Keates', with depressed fracture, became slowly comatose, and the bone was removed. "Whereupon a jet of blood spirted out from a large branch of the middle meningeal artery, and all the symptoms of compression were immediately relieved." Mr. Cock, in the "Guy's Hospital Reports" (Ap. 1842) records a case in which some hours after a severe injury to the head, a man became insensible, and had hemiplegia. There was a severe scalp wound from the forehead to the occiput, but no fracture was visible. An incision was made over the anterior inferior angle of the left parietal bone. No fracture could be discovered there, but as an extravasation of blood was diagnosed, the trephine was applied. A gush of blood took place, a clot was discovered and removed, the stertor almost instantly ceased, and the patient ultimately recovered. Sir Benjamin Brodie says:—"Where no fracture is discoverable, yet if there is other evidence of the injury having fallen on that part of the cranium in which the middle meningeal artery is situated, the use of the trephine may be resorted to on speculation, rather than that the patient should be left to die without an attempt being made for his preservation." The great authority of Pott also supports it.

Although, then, interference in such a case has been opposed, it has the high sanction of those whose opinion is most respected. The cases in which it is possible are few. Of a large number of fractures admitted to the Richmond Hospital in the last seven years, this is the only one in which the symptoms pointed clearly to this remedy; and according to Mr. Erichsen, of University College, he had only seen three cases out of several hundreds during twenty years in which it had "been found advisable to have recourse to trephining for the removal of extravasated blood." Of these only one recovered.

Although admitting that cases of the kind are rare, they are sufficiently numerous to establish a principle that operative interference ought to be undertaken. In the days of Pott, Dease, and O'Halloran the operation was perhaps unnecessarily common. O'Halloran trephined in some hundreds of cases, and he boasts that he had had "no less than four fractured skulls to trepan on a May morning, and frequently one or two."

But though in certain respects the times have not changed since then, we have in our treatment of these cases in some degree swung into another extreme, and the operation is not performed as frequently as it might be. Cases do die in which so far as the presence of blood is concerned relief might be given. The actual position cannot be always diagnosed; but it is a question whether with the improved dressing of wounds, the risk of search would be very great. In the future, at all events, we may expect that our present difficulties will be cleared away. As our knowledge of the localisation of functions advances we may be able to recognise the actual place of effusion, and to save cases that would otherwise be abandoned to expectancy.

Clinical Records.

SHEFFIELD PUBLIC HOSPITAL.

Case of Rheumatic Hyperpyrexia resulting in Death—Post-mortem Appearances.

Under the care of Dr. DYSON,
Physician to the Hospital.

E. K., æt. 38, admitted into hospital on September 4th, 1879, suffering from acute rheumatism. She was a cook by occupation; this was her third attack. At the time of her admission, she was in the third or fourth week of her illness. She was not suffering from much pain; there was the usual profuse acid perspirations, and full quick pulse; her countenance presented a decidedly dirty and earthy-looking aspect. With the exception of a very loud mitral regurgitant murmur, there was nothing to be noted about the heart. Her temperature was 102·5°. Sodæ salicylati, grs. v., every four hours, was ordered, together with beef-tea and milk *ad libitum*. On the 5th, the temperature and pain decreased.

September 7th.—The temperature rose to 104°, and the pulse became quick and irregular. Tinct. digitalis in ℥v. doses was added to the sodæ salicylate mixture. Towards evening the temperature fell to 100°, and in the morning of Sept. 8th, stood at 99·5; in the evening, however, it rose again to 103°.

9th.—Diarrhœa supervened. The sodæ salicylate and tinct. digitalis mixture was omitted, and mist. cretæ, arrowroot, and brandy were ordered, to check it. In spite of all measures to arrest it, it continued to the end.

12th.—House-surgeon was directed to keep a close watch upon the temperature, Dr. Dyson remarking at the time, that, "these earthy-looking cases are likely to run up high."

13th.—Patient delirious, pain less and perspiration arrested. Pulse became excessively weak and dicrotous, 172 per minute and almost uncountable. Slight pericardial friction sound was heard, at the lower edge of the fourth rib.

At 2 a.m., in the morning of the 14th, the house-surgeon was called, the patient being then very delirious and talkative. Tremors and muscular twitchings were well marked. Skin hot and dry. Temp., 107°; pulse, 132, weak and intermitting; resp., 40. The patient was sponged with water at 98°; first the lower limbs for ten minutes each, when the temperature sunk to 105° and the pulse became more perceptible; the right arm and

Digitized by Google

side of chest were next sponged, after tremors next ceased, and considerable improvement in the pulse took place; then the left arm and side of chest, during which, she became conscious, and conversed rationally. The surface of the back being very hot, she was gently rolled over on her right side, to have it sponged; whilst it was being done. the pulse began to get weaker and became irregular. She was replaced on her back and was being gently dried, when hiccough set in, followed by vomiting, and death in a few minutes, apparently from syncope. The post-mortem examination was made shortly after death, and the appearances were as follows:—Muscles deep red; blood still fluid; rigor mortis still present in the legs.

Abdomen.—There was immense distension of the large intestines; the liver was pale and soft; the spleen was very soft, and presented *one* well marked typical specimen of *infarct*, raised above the surface, wedged-shaped on section, white in the centre, with collateral area of congestion.

Kidneys, left.—Of abnormal length, and too pale on section, and presenting a well-marked embolic infarct at upper end. In the *right* was found a very large infarct, which was white and fibrinous, with little area of congestion.

Chest.—The cartilages of the 2nd rib were ossified.

Lungs.—The left pleura was adherent over the upper lobe, but there was no recent lymph. The pleura contained no excess of fluid, nor did the surface of the lungs present any infarcts. On section, the cut surfaces were congested and frothy, but there was no hæmorrhage.

Heart.—Pericardium dry and sticky; no fluid; a little opacity, due to recent lymph, over the right auricle; elsewhere there were no signs of pericarditis. The heart isself was abnormally large. There was deep rose-coloured staining of the endocardium and internal coat of pulmonary artery and aorta. With the exception of a very slight thickening and yellowness of the tricuspid valve cusps, there was no disease present in right side of the heart. On the left side, the lining membrane of the left auricle, was inflamed and covered with a rough layer of lymph, in which, on the posterior surface, were numerous vegetations, and small warty hyperæmic deposits, continuous with the posterior cusp of the mitral valve. The edges of the mitral valve were thickened and very rough; the posterior cusp was glued down; and the anterior cusp was rough and thickened. The left ventricle was hypertrophied and somewhat dilated. With the exception of deep staining, the aortic valves were normal. The substance of the heart was pale and soft.

Brain.—No meningitis. No great injection of the pia mater. There was not the deep staining which was observed in the case of the endocardium. On section, the brain substance showed a great excess of red points, and was moderately firm. No embolism found.

In the course of his remarks upon the case, Dr. Dyson dwelt particularly upon the fall in temperature, a decrease in pain following her admission into hospital, partly accounted for, he thought, by rest, and partly by the administration of sodæ salicylate, frequent doses of which he has always found beneficial in reducing pain and a high temperature, in cases of acute rheumatism. He thinks, however, that the omission of this drug is peculiarly liable to be followed by relapse, more so than is the case with other drugs.

He did not feel in a position to offer any explanation of the occurrence of diarrhœa, which he regarded as a serious accident from the very outset. He noted the fact that this was also a very prominent symptom in a similar case, related by Dr. Wm. Fox. In remarking upon the small amount of pericarditis present, and the absence of tetaniform or choreiform convulsions, he thought that the latter were due rather, when present, to the existence of pericarditis than hyperpyrexia. He expressed himself as strongly opposed to large antipyretic doses of quinine (grs. xv.), but is convinced of the use of cold in some form or other, in these cases of high temperature. He dreads the exertion of removing a patient to a bath, having seen two deaths out of four cases in which this was done. Though less efficacious, he would feel inclined to rely upon the wet pack, or sponging, and in the next case that comes under his notice he intends trying the effect of dry cold, viz., ice in bottles, bags, &c.

He spoke of the necessity of being careful in dealing with sudden hyperpyrexia, occurring in hysterical women, and apparently attended by no other constitutional disturbance, and related an incident which occurred to himself, in the case of a woman under his care for hysterica and enlarged liver, whose temperature stood at 108° occasionally, but who was caught manipulating the instrument to her own standard.

Without desiring to lay too much stress upon it, yet he is inclined to think, that an earthy complexion occurring in a case of rheumatism, is a symptom worth noting and considering, as an aid to prognosis.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

THE last ordinary meeting took place on Friday, December 12th, the President, Dr. E. HEADLAM GREENHOW, in the chair.

Mr. CROFT brought forward

AN ANALYSIS OF FORTY-FIVE CASES OF EXCISION OF THE HIP-JOINT,

and exhibited a large number of the cases on which he had successfully operated.

He said that in making this analysis hisaim had been to show that excision of the hip-joint may be made a successful operation, and that greater success attends the operation when it is performed before abscess has opened than later. He begged that it might be understood that before operation was resorted to in any case every known reliable treatment suitable to the case had been tried to arrest the progress of the disease. Ten cases, as the tables showed, had urgently needed speedy relief. Thirty-five had been treated in the hospital for more extended periods, varying from one month to a year. No case had been operated upon until threatening abscess had manifested itself.

He also begged all present to dismiss from their minds any false impression which had been made on their minds of the number of deaths which had occurred in consequence of the operation. Forty-five operations had been performed on 44 patients, one child having had both joints excised. The records of the cases were arranged in tabular form on four large sheets; on these much labour must have been bestowed. Eighteen cases were cured; 11 were under treatment or observation; 6 patients had died from causes referable directly or indirectly to the operation; one child had died of diphtheria of the air passages; 9 patients had been relieved by operation, but had died, some at long periods, some at shorter periods of time after operation, from causes not attributable to the operation, and from causes from which the children would otherwise have died. The cases cured and the cases dead were arranged in tables, which afforded information on the most important points. Of the 18 cases cured, Mr. Croft stated that he knew certainly that 16 were absolutely cured, and sound and well at the present time, and 12 of them were in the room adjoining the meeting room, and 2 others were potentially cured, in one of whom the sinus had accidentally re-opened just lately, after having been closed for a considerable period, and the other child was cured of her hip disease though she was dying of phthisis.

He stated that 14 of the cases had moveable joints affording flexion and extension, and that 9 enjoyed a considerable range of flexion, and could perform adduction and abduction to some extent. Four could stand *alone* firmly and steadily on the leg which had been operated upon. This fact was especially demonstrated to Messrs. Lister and McCormac after the discussion.

In each patient the limb was straight without any permanent flexion on the pelvis. Each child stood erect without any lordosis of the spine. In many the apparent

Digitized by Google

shortening amounted to three and a-half inches. With regard to that state, Mr. Croft directed attention to a very interesting fact in his series of cases, that in measuring the femur on the side operated upon and comparing it with the normal femur, the difference between the lengths was decidedly less than the distance between the heel and the floor. This he attributed to the preservation of the epiphysis of the great trochanter as a step in the operation, and to the excision being performed sub-periosteally, after Sayre's mode of operating. Mr. Croft had followed Mr. Sayre's mode of excision in almost all his cases. Of the eighteen cases cured twelve were instances of chronic panarthritis, commencing as he believed in the synovial membrane, and six were instances of the similar disease commencing in ostitis and terminating in more or less necrosis. Three of the cases were operated upon antiseptically and two partly antiseptically.

In six abscess had been incised and sinus had persisted, but in only two of the eighteen cured cases were the sinuses chronic in duration. In three perforation of the acetabulum had taken place, and he referred here to the fact that amongst the cases recorded in the list of dead, chronic sinuses had been open in eleven and perforation of the acetabulum had been found in five. Thirteen patients had been under treatment in the hospital for periods varying from two days to three months, four from three to six months, and one for eleven months before operation was resorted to. For further details Mr. Croft referred his audience to the tables, patients, and the preparations of the morbid parts. Thirty-six specimens were exhibited. One of the patients had been brought up from Portsmouth, another from High Wycombe, and another from Beckenham for this particular occasion. Concerning those who were dead, Mr. Croft stated that the total number was sixteen out of forty-five operations. This number included four cases in which, with his present experience, he should not think excision to be the best treatment. The deaths were spread over fourteen years. Five deaths occurred from preventible disease, one from diphtheria of the air passages, three of pyæmia, and one of septikæmia. Six of the total number were attributable, directly or indirectly, to the operation—viz., one from septikæmia, three from pyæmia, one after suppuration in the knee following erysipelas (and he died from shock of amputation of the limb at the hip ten months and more after excision), and one from thrombosis and asthenia sixteen days after excision.

The patient who died from pyæmia, in 1878, was not dressed antiseptically, and it was an exceptionally severe case, the lad being the subject of caries of the lumbar and sacral vertebræ and of psoas abscess. The nine other cases (deaths not attributable to operation) all lived for some length of time after operation. As there was still more or less disease at the seat of operation at the time of death he had put these cases in the list of dead, although death was in no way attributable to operation. The periods of survival were stated and appeared in the tables; they varied in extent from two months and a-half (patient dying from rapid general tuberculosis) to four years.

The causes of death in the nine cases were stated, viz., one from tubercular meningitis without waxy changes in liver, &c.; seven from tubercular disease with waxy changes of liver and kidneys, &c.; one from tubercular disease of lungs, and of other bones than pelvic.

These cases might have been returned as relieved by operation, but in the interests of science Mr. Croft thought it best to trace their progress, and report them as he had done. It seemed, he said, a large proportion of failures to cures, but he ventured to think that with improved diagnosis, by operating in good time, and by improved methods of operating and after-treatment, the proportion of failures will be considerably diminished, and the cures increased in number. The number of failures after operation, or deaths after operation, should be compared with the number of deaths amongst those who are not subjected to operation.

Mr. Croft again protested against the total number recorded as dead being mistaken for the total number of deaths in consequence of operation, or from the sequelæ of operation. The nine patients who died from tubercular disease and waxy disease of liver, &c., would certainly have died from those diseases if the patients had not been operated upon at all. Three of the six cases in which death occurred in consequence directly or indirectly of the operation, would be, according to Mr. Croft's present views, unfit cases for operation. The disease in each case had been in progress for more than three years. In another case the operation was performed with the object of relieving the patient of suffering, and it fulfilled its object.

After some remarks on the little value of statistics which do not supply information with regard to the state of the patient, character of the disease, stage of the disease, and its duration, Mr. Croft proceeded to state that of the eleven cases still under treatment or observation, three were in hospital and eight had returned to their own homes after having been sent to Margate or elsewhere for change.

Reverting to the subject of the advantages attending excision of the joint before sinuses have formed and become chronic, the author stated that of the cases of cure, 18 in number, 6 only had had sinuses, 2 of these chronic, and 4 recent; whilst of those included in the dead list 11 were the subjects of open chronic sinus or sinuses before operation. Amongst the cured and dead cases there are 3 and 5 cases of "perforation" respectively. He thought it a fair inference that chronic sinuses and the occurrence of perforations of the acetabulum do severally or together influence the progress of cases for the worse. Mr. Croft argued from this in favour of early antiseptic operation before abscess has burst and sinus formed.

Here Mr. Croft said that he felt anxious not to take up too much of the time of the meeting that evening by his own paper, yet there were several points he felt called upon to refer to:—

1st.—The advantages which he claimed for early, or relatively early, operation.

2nd.—Formulæ with respect to indications for operative interference.

3rd.—The mode of operating with reference to the periosteum, the leaving behind the epiphysis of the great trochanter, the line of section of the femur, removing parts freely, the line of incision through the soft parts, and the employment of antiseptics.

4th.—The mode of after-treatment.

5th.—The causes of failures in excision of this joint.

6th.—The comparison of limbs after excision with limbs of those who get well without operation.

7th.—The time taken to get well by those not operated on compared with the time taken to get well by those successfully operated on.

On this occasion he would only present a summary of what he had to say on three of these topics, viz., the 1st, 2nd, and the 5th.

1st.—The formulæ with reference to indications for operative interference:—

(*a*) When there is a collection of fluid in and about the joint in a case of well-marked hip disease in which all the physical signs are present, and especially starting pains, antiseptic incision should be made, as it the surgeon intended to excise, and he should only desist on finding the articular structures in a condition from which they could rapidly recover and yield a moveable joint.

(*b*) When pus associated with panarthritis (strumous disease of joint) is known to be present, even if the surgeon is uncertain with regard to the state of the bones, he should excise.

(*c*) If the surgeon is certain that necrosis has occurred he should excise.

Causes of failure in excision of this joint:—(*a*) Operating too late in the progress of the case, not removing enough (1) in the acetabular region, (2) of the femoral portion, (3) of the synovial membrane and capsule. (*b*) Not providing free exit for discharges. (*c*) Not operating antiseptically.

Mr. Croft asked here why are not hip excisions as successful as excisions at the knee-joint? The reply he gave was that in excising the acetabular portion of the joint the surgeon did not remove the disease so thoroughly as it might be removed at the femoral portion of the knee-joint. Lastly, he claimed for what he had termed early, or relatively early, operation—

1. That in cases of *tubercular* disease early complete excision affords the best prospect of cure.

2. Immediate relief from pain of tension and spasmodic starting pains.

3. That it is made before muscles are much atrophied or stiffened by inflammation products.

4. That it shortened the duration of suffering and illness.

5. That it enables the child to go about earlier than it could if left without interventive treatment.

6. That it enables the surgeon to procure a painless moveable joint at the hips.

7. That the shortening is only a trifle more than it is in the

Digitized by Google

most favourable cases of ankylosis after destructive strumous disease of the joint.

After the meeting broke up Mr. Lister examined some of the patients who had remained to that late hour, viz., a quarter to eleven o'clock, and Mr. Croft satisfied Mr. Lister and Mr. McCormac that four could stand steadily and firmly on the leg which had been operated upon. These patients were Charles Boswell, now fifteen years of age, who was operated on eight years ago; Albert Curry, now ten years of age, who was operated upon nearly seven years was operated upon nearly four years ago; and Hector Webb, ago; Margaret MacCarthy, now sixteen years of age, who now eleven years of age, who was operated upon nearly two years ago.

The parts removed from thirty-six of the forty-five joints were displayed in bottles placed on the tables, but Mr. Croft assumed that the pathological question would not be entered upon by the members of this Society.

He then left the matter in the hands of the meeting.

Before opening the discussion, the President ruled that Mr. Parker should read his paper also.

Mr. R. W. PARKER

ON A NEW METHOD OF EXCISING THE HIP-JOINT, WITH REMARKS ON THE PATHOLOGY AND TREATMENT OF HIP-DISEASE.

It was in consequence of some remarks by Mr. Hulke and Mr. Bryant, and in accordance with a suggestion made by the President at the last meeting of the Society, that these notes of epiphyseal necrosis were brought forward. For want of time, however, only one case could be read. This case was selected because it illustrated, first, a new method of operating; second, epiphyseal necrosis; and third, the influence which the social condition of the patient must always exercise on the treatment to be recommended.

M. Y., æt. 8, was admitted into the East London Hospital for Children in March, 1879. The following notes were made by Mr. R. E. R. Morse. For two or three weeks she has complained of acute pain in the right knee and leg; she was feverish, and without appetite; was kept in bed. On admission, the upper part of the thigh and the region of the hip were found much swollen and very painful. There was no appreciable fluctuation; the soft parts in the groin were slightly œdematous; there were no enlargements of glands. Passive movements caused great pain. An extension apparatus was ordered. At the end of a fortnight she was examined under chloroform, seeing that her condition was worse than on admission. Grating was not discovered in the joint; neither could fluctuation be made out—the femur moved freely in the acetabulum. The temperature was high and variable. A low typhoid condition supervened, and for a time she was very ill. At the end of another month she had materially improved in her health, but her local trouble on the other hand continued to progress. An abscess now formed in the upper part of the thigh, which had to be opened. Eleven weeks after her admission she was again chloroformed, in order the better to examine the joint. Grating was now found, and there was a free discharge of pus from the wound. Excision was then decided upon.

Operation.—An incision was made from the anterior superior spine of the ileum downwards along the *anterior* margin of the great trochanter, cutting between the sartorius and rectus muscles on the inner side, and the tensor fasciæ and the borders of the two lesser glutei on the outer side. This exposed the anterior surface of the neck of the femur, as the capsule was found to have been destroyed by the disease. The diseased bone was sawn off *in situ* with a key-hole saw. After removing the bone with sequestrum forceps, and while examining into the condition of the acetabulum a portion of the epiphysis was found detached and necrosed. The child made a slow recovery, and was sent into the country in about two months after the operation. She can now get about, but there are still some open sinuses. She is comparatively fat and well.

CASE II.—J. A., æt. 6, was admitted with an abscess in the upper and outer part of the thigh; it had been noticed three weeks. Pus was evacuated on at least two occasions, but the boy did not improve. Three months after his admission grating was detected in the joint, which was excised. The head of the femur was found detached and necrosed. He is now well, and walking about.

CASE III.—S. B., æt. 14, admitted with a large abscess involving the upper third of the thigh. The boy rapidly lost flesh; the hip-joint became affected secondarily; caries of the femur set in, and destroyed its upper third. Amputation at the hip was finally decided on and carried out. The head of the bone was found necrosed in the acetabulum. The boy died.

CASE IV.—E. E., æt. 3, had a fall three weeks before her admission. A week later the thigh began to swell, and the hip-joint to be painful. Three months later, after extension and rest had been tried, there was grating in the joint with abscess. Excision was performed; the remains of the head were found detached and carious in the acetabulum. She has made a good recovery, though she cannot yet walk.

CASE V.—T. A., æt. 7. Began to limp when three years old, and has suffered "on and off" ever since. He was taken in and kept in the recumbent position, and an extension apparatus applied. But an abscess formed; and within the next six weeks there was palpable grating in the joint. Excision was performed, and the head of the bone was found detached. It was not necrosed.

General Remarks. — Methods of Operating.—This new method of exposing the joint and removing the carious bone was proposed because it avoided the necessity of cutting *across* any muscular fibres. The posterior incision, on the contrary, must separate the glutei and many other muscles from the upper end of the femur, besides interfering with the vascular anastomoses. He thought it desirable, too, to saw off the bone *in situ*, rather than forcibly push up the bone through the wound; for in doing so the periosteum was frequently detached from the shaft of the femur for some distance below the disease.

As regards the usual incision along the *posterior* border of the trochanter, he could only say that several very large muscles had to be divided near their insertions, and that considerable interference with the vascular anastomoses of the part must also result.

Epiphyseal Necrosis.—He had done eight excisions in all, and had found this epiphyseal necrosis in five cases. It was not until Mr. Hulke pointed out the fact that he (Mr. Parker) became aware of the rarity of this affection, for, agreeing fully as he did with the view that caries of the neck was the most frequent pathological condition in hip disease, he should rather expect to find necrosis of the epiphysis, owing to the impaired nutrition, and the interference with the physical condition of the surface to which it was attached. On inquiry he found that many cases had occurred, and he believed that if looked for it would be more frequently present than absent. The points in his cases which were common to all, or the majority, were—progressive disease in spite of careful nursing and treatment, comparatively rapid onset and progress, early formation of abscess, the young age of the patients.

The Social Condition of the Patients.—It was not necessary to say what an important influence this would have on the plan of treatment which could be recommended in a given case, for clearly the child of a poor labouring man could not be adequately treated at home. The existing hospitals, on the other hand, were not able to carry out an expectant plan of treatment, and the question of operative interference then was the only alternative.

Results of the Disease.—Most unsatisfactory without adequate treatment in a hospital. Even under favourable circumstances it was far from encouraging, as the above related cases showed. Seeing how many cases which recovered were found to have the femur flexed on the pelvis, was there not possibly a clinical indication therein, and were we giving to a diseased joint that absolute physiological rest which was essential for a cure in forcibly keeping up extension during lengthened periods? While he was willing to admit that the results of operation at the present time were not entirely satisfactory, he would ask, was not this due to our waiting until the strength was gone, until the limb was wasted to a mere outline, until the disease had attacked surrounding structures, and until, in many cases, secondary disease in distant organs had been induced by the long-continued suppuration such as rendered a "cure" all but a physical impossibility.

The epiphyseal sequestra were exhibited.

Mr. HOLMES felt that Mr. Croft's exhaustive report left him little to say. When younger he had performed this operation many times, but not so often as Mr. Croft. The results of the operation must, he said, depend entirely on the selection of the cases, since the indications in favour of or against operation vary materially with the circumstances by which the patient is surrounded. In hospital cases an unfavourable result

Digitized by Google

must be experienced because of the bad hygienic surroundings through the patient's existence; but in private practice, as a consequence of the greater care and better health precautions, greatly improved results followed operation. *In limine*, hospital treatment so continuously fails of giving any permanent benefit in these cases that the surgeon ultimately resorts to the knife in sheer despair. Such, however, he could not regard as the correct course. He thought it to be improper treatment to make incision even antiseptically into an abscess in the joint. He had been accustomed once to excise a joint if he proved to himself the existence of an abscess, and of crepitation, but had given up the practice. He felt convinced that a patient whose health was not irredeemably shattered, and with only a superficial caries of bone, might recover without operative interference. The natural cure resulting is far more perfect than any that will succeed to surgical efforts. There is less shortening in such cases, the anchylosis is more perfect, and the general result far more favourable than that brought about artificially. He had never seen a patient thus operated on able to stand erect afterwards; dissection proved that the union following excision is chiefly ligamentous. He therefore urged that when possible the cure should be by natural means. He did not, however, argue against operation *in toto*, for in some cases he admitted it is essential to improvement, but all the more, therefore, *indications* ought to guide the efforts of the surgeon. A recent case of extensive caries, which he had seen with Mr. Pick, was one demanding operation undoubtedly; and similarly when sequestra existed in the joint they could be removed only after the operation for excision. Preservation of the joint under such circumstauces is plainly impossible; excision, therefore, is the *only* method for relieving them. But excision is not indicated by abscess and simple caries. Cure is possible in such cases by means of opening the abscess, freely washing the wound, and subsequently submitting the joint to regular extension at not too distant intervals. He urged that the surgeon must not be influenced by a death-rate of whatever proportion, but be guided in each case on its own merits. The number of fatalities will always be subject to wide variation; the period of the disease, and the patient's condition much affect the result. He was certain that excision of the hip-joint will never be as successful an operation as the analogous one on the knee, for the reason that it is not possible to remove bone in extent sufficient to eradicate the whole mass of disease. Of antiseptic treatment in these cases he had no experience. He believed the average outcome of operations would be always about the same—one-third would die, one-third be cured, one-third doubtful.

Mr. HULKE thought Mr. Croft's analysis a very valuable contribution to surgical literature, but it would require careful and attentive study. His own experience of these operations was, he said, limited. Until he heard Mr. Croft's explanation, he had been dismayed to find the number of deaths after operation so large, but was glad to know that all were not due to the operation itself. Six deaths, however, out of a total of 45 cases, gave a mortality of about 1 in 7, and this was considerable. He had recently gathered statistics of hospital practice, and out of 313 cases of joint disease he found the hip-joint involved in 86, but of these only 6 could be truely described as morbus coxæ. Excision was performed in 16 out of these, and in only one did death ensue immediately from operation. This, he believed, would be a fair average, if cases were properly selected. He agreed with Mr. Holmes entirely, and his examination of the cases then exhibited induced him to think that the operation had possibly been undertaken where it was not always necessary. From 1 boy exhibited he elicited that the disease had pronounced itself only a month before excision was resorted to, and when treatment had been undergone for no more than one week. He personally, trusted mainly to the indications afforded by patients' general condition; if the health was fairly good—that is, if ground was not being lost—he did not feel called on to excise, but only when there was obvious deterioration. He approved free incision as an aid to copious drainage, and always treated the wound freely with chloride of zinc. He did not resort to Listerism, but, apart from it, avoided chance of putrefactive changes as far as possible, thereby obtaining good results. Mr. Hulke called attention to a particular form of splint (exhibited), which he declared to be more serviceable than the Thomas's splint, mentioned by Mr. Croft.

Professor LISTER said he had been pleased to hear Mr. Hulke's testimony in favour of chloride of zinc, having used it freely himself in such cases. It prevented putrefaction in presence of septic elements, and was invaluable where sinuses giving exit to putrid material existed. He had seen many lives saved through it. Employed together with free drainage in excision, risk might be practically avoided. He had met with no case indicating amputation rather than excision. Since witnessing Sayre's method at Philadelphia, had always followed it. It limited hæmorrhage, permitted free access to the joint and acetabulum, is sub-periosteal, and thus presents many important advantages for which its employment is to be advocated. He was of opinion that if a joint *must* be opened, it had better be done so freely, than in the limited fashion Mr. Parker had suggested. In the last case he had operated on, a young lady had been for a long time afflicted with hip disease; many sinuses existed, and a profuse discharge. He had excised after Sayre's method, and perfect ankylosis ensued. He found a mass of exfoliation and diseased bone, but the case was doing well at this time. Here, too, he had made copious use of zinc chloride. This case was a proof that the disease is met with, even though rarely, in private practice. Mr. Holmes had not referred to the treatment of abscesses antiseptically in which openings appeared. He felt convinced himself that such an abscess *should* be opened with the adoption of every possible precaution against putrefaction, and evils attendant thereon. He was disappointed to hear only "free washing" spoken of in the present time, and was quite certain that it would be productive of no results comparable to those obtained by antiseptic methods. The treatment of cases in which no shortening of the limb has taken place is a matter of extreme importance. In three cases of the kind in King's College Hospital the abscesses (in adults) were of rheumatic origin. They had been opened antiseptically; no fever supervened, no shortening took place, and good moveable joints remained. Cases of this nature were rightly productive of much satisfaction. He had seen many strumous patients in whom good results had followed opening of the abscesses, and he was firmly convinced that the operation (incision), where practicable, resulted in a more permanent recovery than can be obtained by means of excision, not excepting cases in which exfoliation has occurred. In one instance he had found a considerable quantity of half-necrosed bone present, and judged excision would be necessary. Determining, however, to wait awhile before operating, and submitting the joint meantime to antiseptic treatment, almost perfect restoration took place, only a small sinus being left. A house-surgeon, however, thinking recovery secured, omitted, on his own responsibility, the antiseptic precautions at this stage; suppuration quickly ensued, and eventually amputation was necessary. Antiseptic treatment, continued Mr. Lister, should be invariably followed where an abscess with unbroken surface presents. By this method better results may be anticipated than through excision.

Mr. MORRANT BAKER said he had performed twenty-four operations for hip-joint excision; two patients died from the immediate effects, and one some considerable time after. He did not think a greater mortality than this ought to follow the operation. The time it occupied need not be excessive, four or five, or at most seven or eight, minutes sufficing, and by using a fine saw, with ordinary care, there ought to be no greater danger incurred by the patient than that attending simple incision into the joint. He was an advocate of free drainage; when the trochanter is left he had never noticed any want of firmness in the joint. A perfect result, however, could not be anticipated, the conditions under which the disease is contracted standing in the way of such a desirable consummation. He felt that the operation of excision would give the patient a better chance of a comfortable existence, but the indications should be the sole guide to the operation. Rules for guidance cannot be laid down with any certainty; individial judgment must determine the merits of each case. Excision is an unwise proceeding if much ankylosis has taken place. The presence of loose sequestra must always be a strong argument in favour of excision. He had found such dead bone in many of his own cases. He exhibited a case in which he discovered the head of the bone (femur) lying loose in the acetabulum. The influence of amyloid disease, continued Mr. Baker, is not sufficiently considered in its reference to this disease. Even when much advanced, it did not necessarily prevent ultimate recovery, a case in illustration having been under his notice in St. Bartholomew's Hospital. He urged, however, that generalisations from a single case were not admissible. He was convinced that good results would follow excision in a vast number of cases.

Digitized by Google

Mr. J. Wood had performed the operation for excision very often, and frequently where advanced amyloid disease existed. He thought cure would follow proper rest and extension in many cases; but occasionally excision was indicated from the first. In his own practice he interfered as little as possible with the natural position of the muscles, and could point to very successful results, even where he had removed a considerable portion of the pelvis. One case in which he omitted full antiseptic treatment, but employed zinc chloride, carbolic acid lotion, and full drainage, did very well. He thought the conduct of the surgeon should be guided by a consideration of the symptoms *en masse*, but when dead bone is felt with the probe, then operation is imperatively called for. He deprecated the exposure of the bone, but advocated its removal sub-periosteally, and through as small an incision as possible, the operation being thus reduced to little more than that required to open an abscess. He was inclined to operate in those cases only in which the efforts of nature to effect a cure by ankylosis had manifestly failed of success.

Mr. McCormac was of opinion that the mortality in Mr. Croft's cases was not excessive, consideration being had to the unfavourable nature of the average hospital patients. He had not followed out the histories of his own cases so completely as Mr. Croft had done his. He thought sufficient stress had not been laid, during discussion, on the character of disease indicating necessity for operation. In a large number of cases the white swelling of the hip-joint is connected with the existence of miliary tubercle in the bone itself, and Prof. Kœnig, of Göttingen, had demonstrated this in sixty-nine out of seventy-one cases. This must be a very urgent reason for *early* operation, and he believed that a good functional limb could be expected only after early interference with the course of the disease.

Mr. Howse considered it surprising that so many favourable results did follow late operations. He advocated the removal of the trochanter major, but condemned the closure of the wound by sutures. The trochanter, if left, would act as a shield before the acetabulum, and thus retain any carious bone, to the patient's injury. He objected also to a too free removal of acetabulum and surrounding pelvis, as likely to induce collection of pus between the pelvic fascia and wall.

The President proposed that a committee, consisting of Messrs. Hulke, Holmes, Bryant, Croft, and Howard Marsh, be appointed to report on the whole subject under discussion.

The motion having been carried,

Mr. Croft replied to the criticisms passed on his paper. He had feared, he said, that he would be severely handled, but could not think his conclusions materially shaken. Mr. Holmes' statement concerning the unsatisfactory limb left after operation did not convey any forcible objection to operative interference; while adversely critising the formulæ he had given in his paper, Mr. Holmes had suggested no better or reliable means of deciding the necessity of making exploratory incisions; and regarding the early operation, Mr. McCormac had added his testimony in favour of it, by dilating on the frequency of tubercular infection. No one, said Mr. Croft, who would examine his preparation, could accuse him of performing any single operation without full reason; and he did not think any improvement on his method of proceeding had been suggested. The patient referred to by Mr. Hulke, as having been operated on a month after the onset of the symptoms of disease, was suffering from acute necrosis, and in the extremest agony, the operation being imperative in his case. He had at different times used two incisions, a longitudinal and Y-shaped one: had followed Sayre's mode, and always preserved the great trochanter without severing the attached muscles. In many cases he could show that the process had been re-united. He did not find it cause any obstruction, as suggested by Mr. Howse, and that gentleman was also mistaken in supposing that he (Mr. Croft) intended to imply that excision must invariably follow distension and grating in the joint. Where, however, a collection of pus existed, and advanced disorganisation, then even in the absence of any sinus, an incision should be made to permit accurate examination of the part.

SURGICAL SOCIETY OF IRELAND.

Mr. Wm. Thomson on

A SUCCESSFUL CASE OF TREPHINING OF THE SKULL.

which will be found at page 517.

Mr. W. Thornley Stoker.—As one of the surgeons who assisted Mr. Thomson at this operation, I may be allowed to bear my testimony to the accuracy of the diagnosis which was made, and the success which followed in the treatment, and also to the unexaggerated account he has given of a case which must be looked upon as a typical and valuable one. Examples of hæmorrhage suitable for the use of the trephine are so rare, it is very important that such a one as the present should not pass without record. In another particular also I think the case is of value. I mean with reference to the difficulty of diagnosing, when the dura mater has been exposed, subdural hæmorrhage. In this case, as Mr. Thomson has mentioned, there was considerable difficulty in seeing whether blood lay under the dura mater or not; it was blue and discoloured. Mr. Prescott Hewitt, whose authority in injuries of this sort cannot be doubted, has recorded twenty-five cases which resulted in death in St. George's Hospital from severe injuries of the skull, followed by hæmorrhage between the bone and dura mater; and in one of these it was also beneath that membrane as well. Recollecting this fact it is most important we should have a record of a case like the present, where the difficulty was found and overcome.

Mr. Wheeler.—It has been my lot for the last fourteen or fifteen years to see a great many cases of fracture of the skull. Some were fractures of the base, in which operative procedure was unnecessary, and in these the symptoms that arose were simply treated. But in others which I have seen, and which have been under my care, operative procedure was necessary. One of these was such as Mr. Thomson has brought forward, namely, where there is extravasation of blood following a fall. Mr. Wheeler then spoke on the general subject of trephining, and gave illustrative cases. With regard to the question Mr. Thomson raises as to the justifiability of operating in a case like the one he brings forward, nothing could be more justifiable. Here was a case in which the patient got a fall, in which consciousness ceased and returned, and convulsions and hemiplegia followed. Nothing could point more clearly to an operation than that, and nothing could be more likely to relieve the patient, even though the operation might not be successful. I knew a case in which a man received a blow in the course of the meningeal artery. Unconsciousness for a time ensued. Consciousness returned, and then perfect unconsciousness supervened. I advocated using the trephine in the region of the meningeal artery, but objections were raised, and the patient died. If that patient had been operated on he would have had a chance. With regard to whether the blood is either superficial to or beneath the membranes, it is a matter of perfect indifference to the surgeon; he knows his patient is unconscious from pressure, and he fails to perform his duty unless he gives the patient a chance by trephining. If he finds the blood is over the dura mater, well and good; if not, he has the alternative of cutting into the dura mater and giving the patient a chance, which he could not have without adopting that course.

Mr. L. H. Ormsby.—I think the trephine is not such a simple instrument to use on the skull as has been indicated. It is not always necessary to use the trephine, because you can elevate very often without using it. A case occurs to me of a woman who was 3 months ago at Meath Hospital. She had a depressed bone, and probably extravasation of blood as well, and we had the instrument to perform the operation of trephining. However, I enlarged the wound, and I was able, without using the trephine—and probably thereby rendering the operation more serious as regards the result—with a little manipulation, to get out a portion of bone about the size of a farthing, and also some of the extravasated blood. I got it out without incurring the serious results that might accrue to the patient from trephining. As operating surgeons see more of these cases than others do, it is as well to mention the fact that elevation may take the place of trephining very often.

Mr. Thomson replied. He said—In the majority of the observations that have been made there has been a support of the views I have endeavoured to put forward and the truth of the diagnosis and the line of treatment in this particular case. With reference to the question of blood beneath the dura mater, which Mr. Stoker has referred to, and the difficulty of diagnosing it, it occurs to me that even in such a case the removal of the bone for the supposed extravasation upon the dura mater may have the effect of removing that deeper pressure, and so relieve the patient from symptoms if it be a deep clot that is producing them. Of course there is nothing to prevent both these two clots being present; and supposing the deeper clot was present, we did wisely to explore with the

Digitized by Google

trephine. Mr. Wheeler's observations have gone into a much wider field than I attempted to deal with. I tried to confine myself to the question of extravasated blood within the cranium, not dealing with trephining in general. I mentioned one in which it was a simple case of diagnosis of extravasation of blood without injury. As to Mr. Ormsby's observations, I think he has not, perhaps, quite caught up the question under discussion. Nobody would deny that an elevator is a most useful instrument in the proper place; but it seems to me that to suggest an elevator might be used in a case of linear fracture is out of the question. In the case he quotes himself it was quite easy, I have no doubt, to use that instrument in preference to the trephine, because it was apparently a comminuted fracture. At all events, there was a distinct piece of bone fractured from the general mass of the skull, which it was quite possible to remove. In a case of that kind where it is possible to use an elevator I have no doubt every surgeon would approve of the practice, but the expediency of using the trephine in a case of linear fracture in order to remove a portion of bone to get down to a deeper point of pressure will not be questioned.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 17, 1879.

ANTISEPTIC SURGERY.

PROFESSOR LISTER'S long-expected reply to the recent utterances of those who have constituted themselves the champions of the expectant treatment of wounds, fully confirms and justifies our repeated demand that his vindication of his own system was alone necessary to establish the triumph of antiseptic surgery. Prepared as we have been to anticipate that the answer, when it did go forth, would be complete and convincing, we nevertheless marvel at the utter certainty, the sweeping assurance that it carries with it. The incontrovertible nature of the evidence adduced on Wednesday week, before the meeting at St. Thomas's Hospital, is the severest condemnation that can be passed on the culpable error of those who persistently deny the truths exemplified in the manifold precautions against septic poisoning observed by surgeons of the modern school. Not from the experience of one only, nor from two or three, but from the accumulated observations of an army of practical workers, have been deduced the arrays of facts that, in their combined strength, constitute an irresistible, argument in favour of Listerism, and that forces admiration, even where it fails to attract belief. The progressive advance in the way of safety that has been achieved, and is still continuing, an advance coincident with the introduction of the antiseptic method, and steadily progressing as the details of that method have been more and more perfected, is too palpably clear to the most careless onlooker, to admit of any denial of the primary truth that it IS. Struggle as they may against the tide of evidence; strive as they will, and have, to distort the facts that exist to their discredit; this yet remains incontestible, unanswerable, that, viz., Listerism has been productive of results that will be everlasting memorials to the genius of its founder, and a legacy of incalculable good to mankind for all time.

Avowing that he was a surgeon of the pre-antiseptic period, Mr. Bryant declared himself unwilling to yield the whole glory of modern surgical improvements to the influence exerted against disease by antiseptic treatment Admitting that vast changes bad come over the methods of dealing with wounds, with their dressing, and all subsequent treatment, and yielding to those who claim that much of this is due to the impetus given in this direction by Mr. Lister, he yet strenuously resisted the ascription of any part of this improvement to the antiseptic agent *per se*. To the excellence of modern hygienic arrangements, to the better comprehension of the conditions and etiology of disease, to a keener appreciation of pathlogical transformations and the influence of these on morbid changes, to the detailed observance of nursing and dietary minutiæ, to these, and to these alone would Mr. Bryant, and those like Mr. Savory, who exercise determined opposition to the claims of antiseptists, ascribe any part in the vast improvement that all bear witness to.

A sorry attempt was made by Mr. Bryant to detract from the merits of the Listerian treatment, by quoting from a table of operations performed according to its rules; bnt in number so limited, and in detail so meagre, that none save the speaker were, for a moment, affected by the conclusions he drew from it. As a champion of ancient surgery it must be candidly confessed, Mr. Bryant showed to eminent disadvantage; and in the exposure of his fallacious arguments that followed, we feel assured he derived a greater insight into the truths he has hitherto repelled, than he has ever before attained to.

We do not propose to follow the details of every speech that was made on this occasion, but will refer only to such points as were raised in pointed illustration of the benefits that have followed the adoption of the antiseptic method. And in this connection, the evidence of Mr. Smith (St. Bartholomew's) was most conclusive, both when it bore on his own practice, and when he quoted the experience of Professor von Nussbaum, at Munich. A very lately issued work of the eminent German was referred to, in which he relates that his personal experience of antiseptic surgery is conclusive to a degree. Much to his distress

Digitized by Google

—Professor Lister described it as causing him "mental agony,"—eighty per cent. of the cases under his care in the Allgemeine Krankenhaus, were victims to one or other form of septic disease; and in spite of every precaution on his part, notwithstanding his unceasing endeavours to eradicate the seeds of death, this large percentage continued unabated. But "since he introduced antiseptic treatment, he has not had one case of pyæmia, he has not had one case of hospital gangrene, although he previously had eighty per cent. of his wounds affected with it. He has abolished erysipelas altogether." The absolute truth of this cannot be subject to doubt, for it is verified by the post-mortem demonstrations of the professor of pathology; and though Professor Lister volunteered the statement, none, we opine, save the obdurate sceptic, would dare to impugn the accuracy of figures compiled under the conditions that attended Professor von Nussbaum's assertions.

Once more, Mr. Spencer Wells, by his testimony, proved in the most complete fashion the invincible nature of the improvements that have been made. Though for twenty years, keenly alive to every available opportunity of adding to the effectiveness and safety of his operative procedures, in the special practice with which he will be always associated in name, he was impelled to utter the conclusion that a much more rapid progress had been made in surgical science since the introduction of the antiseptic method, than had been possible under older modes. And notwithstanding his careful endeavours to eliminate the cause of death after ovariotomy had been productive of wonderful results, enabling him to reduce the mortality from 34 to 28, and 22, and 14, and finally 10 per cent., yet the consequence of his ultimate adoption, two years ago, of all the detailed precautions of Listerism had been startling from the large and sudden change in his statistical returns under the system. In his last 84 cases antiseptic rules had been rigidly adhered to, and for a result he could point to a series of 38 cases in succession without a single fatal issue; and out of the total number operated on, 78 had recovered, as against six who had succumbed.

Is not this, we are tempted to inquire, of itself, a sufficient refutation of the insinuations made against a system that can produce such aggregate results? More, however, can be urged in its favour; and this more Prof. Lister's speech embodied in profusion. For a moment he dealt with the tables prepared from the statistical returns of operations at St. Bartholomew's Hospital, and used by Mr. Savory in his address at Cork. Briefly, he showed that these were utterly untrustworthy criteria of the value of pure-water surgery, for in numerous details the treatment of the wound was essentially antiseptic. Did not the catgut ligature, the employment of carbolised oil, and the carbolised silk protective, all tend in the direction of preventing septic poisoning, in the same fashion, if not in the same degree, as the observance of complete antiseptic precautions? And again, Mr. Savory's statistics were not those derived from the practice of himself alone, but were gathered from the results obtained by four separate surgeons, two of whom, at least, were practical exponents of the doctrine of Listerism. In every way, the fallacy of the arguments based on such erroneous premises, was but too apparent.

From his own private work, however Mr. Lister produced the most effective weapon to destroy the conclusions of his antagonists; and the crushing weight of the bolt he flung, will long deaden the energy of those whose strength has been strung to declaim against the truth. Generously, willing to afford every advantage to his opponents, Prof. Lister, when comparing his own results with the best ever produced in proof of the efficacy of the non-antiseptic treatment, removed from his tables every series of figures, to which even the *least* captious critic could take exception. And the consequence of the comparison is to show the advantage of the modern method of operation and treatment, by the occurrence of a less number of deaths per cent. under it, than under the older methods, even when these are calculated in the manner most favourable to the aspersors of Listerism.

We are anxious not to go too minutely into the question of these numbers here, but one series of figures read by Mr. Lister we cannot forbear quoting. In 295 operations done in two years, but one case of blood-poisoning occurred, and this in an instance where a plastic operation for a new nose had been performed. The known difficulty of avoiding chance infection during operations on the face might well excuse this single mishap out of so large a total; but Mr. Lister, in the truth of his nature, admits a further reason, scorning to seek any cover for an error that is to him a crime. He says, "I endeavoured to turn one side of the ascending process of the superior maxillary bone, to make a support for the flap, and I split the bone; and I was conscious at the time I had made a mistake. That was a case in which antiseptic treatment was impossible, in consequence of communication with the nasal cavity." This only, out of 295 cases! Again, of 80 major amputations, nine deaths followed operation; 11·25 per cent! The mortality assigned to this class of operations by Mr. Erichsen is *thirty-five to fifty* per cent. Here again Mr. Lister deprecates such an ill measure of success, as it appears to him, and proceeds to explain,—"One was a primary amputation. I did the operation practically without any hope of saving him; but I have seen a patient come round after being perfectly pulseless, and I deemed it my duty to try it." And the great majority of fatal issues have some such, or equivalent, history attached to them.

We will allude only to one other topic in connection with this question. The immense benefit conferred on suffering humanity by antiseptic surgery is less perhaps in the safety with which major operations can now be performed, than to the blessings, little it may be in themselves, but taken together of most imposing magnitude, which follow from the application of the method to alleviate the pain and inconvenience of small affections. Abscesses can be opened with absolute immunity from all danger under the spray of carbolised water; and protected by the carbolic dressings they will heal with no single untoward symptom. How painful they are, and how apt in some situations to lead to the most distressing consequences, if incautiously opened and exposed, needs no enforcing. Plain is it then, that a means by which all this danger is avoided, must be a valuable, nay an invaluable, aid to the operative surgeon.

Nothing was needed, at the present time, so much as

Digitized by Google

an authoritative reply from Mr. Lister to those who have rejected the merits of his great benefaction. This reply has now been uttered, but we fear it will not avail to crush every remnant of opposition. But for our conviction of its utter futility, we could give expression to the earnest wish that henceforth no more would be heard in denial to the overwhelming proof of the invariable usefulness of antiseptic precautions in surgical operations. We know, however, and we can but grieve to know it, that there are many amongst us so wedded to the prejudices of the past, to whom the traditions of an older generation are endeared by the associations and the ties of a dead and gone time, that the flood-lights of modern discovery are powerless to light the way that shall guide them to the truth. Held high in the admiration of the younger men to whom they are leaders, and who regard them with a chivalrous devotion, in that they embody the wisdom and experience of the past, what wonder, we ask, that the generous enthusiasm of youth enlists itself on their behalf; and resolves to encounter the outer world in bold defence of the tenets sanctified through association with the masters they delight to honour. It is this tendency that must be combated with; it is this willingness on the part of the student world to adopt the doctrine approved by the teacher who has gained their confidence and love; and in so far as the attempt to do this is successful, by so much will the cause of truth progress. We see in the opposition that centres now in a few great leaders of opinion, how, in the future, it will be continued by the more eminent of those who inherit the thoughts and ideas of these few men; and though it is right to do all that can be done to push further and further into the realms of the unknown, the limits that set round the known, we ought never to be unmindful of the insidious working of the living influence brought to bear on the growing surgeon of the future.

MEDICAL ELECTORAL INFLUENCES IN IRELAND.

We have disinterred, a few days since, from a bundle of copy, which lack of space had obliged us to set aside, the following extract from a leading article published in the *Tuam News*, many months since, in reference to a pending dispensary election, and a report of the proceedings at a dispensary election in the same county and about the same date, taken from a paper whose business it was to gloss over the riot and intimidation of that occasion. The excerpts have rather gained than lost in interest by their being held over, because it is not now open to anyone to say that we have condemned the tenets which they set forth in the interest of any candidate for office. We reprint the articles now as illustrations of the utter unsoundness of the existing election system in Ireland, and the total unfitness of the class whose duty it is to elect to perform any such function with impartiality:—

"In matters of such importance as the return of a Catholic doctor instead of a Protestant, to take charge of the poor of a Catholic district, there should not be the slightest room for the Catholic members of the Committee doubting for whom they are bound, as a matter of conscience, to record their vote. Casting aside all other motives, the Catholic member of the Committee is strictly and conscientiously bound to secure, as far as in him lies, both by vote as well as by his influence, the return of the Catholic. We cannot understand how any Catholic who has a vote and who records that vote against the Catholic doctor, *can expect much respect or courtesy from the Church whose principles he rejects* by his co-operation. We have not the slightest hesitation in stating, that whenever there is a question of appointing a Catholic or Protestant doctor to a dispensary district, that the office should be given to the Catholic doctor."

"According to announcement a meeting of the dispensary committee was held for the purpose of appointing a medical officer. There were only two candidates, the popular candidate, and the nominee of the conservative element. It appears that for some time past each party canvassed closely for their respective candidates. Party feeling ran so high that the authorities drafted in over 150 police, and ordered the public houses to be kept closed durin the day, anticipating a riot. The people feeling that justice would not be done them in forcing a doctor on them against their wishes, assembled in their thousands to enter their protest, both by words and signatures, against the proceedings

"We are glad to say, with the exception of some hooting and hissing of those whom they thought merited it, they conducted themselves in a most orderly manner, leaving the Royals, R.M.s, S.I.s, after their grand military display of swords and rifles, nothing more to do than shiver under the influence of a cold, biting, westerly breeze. Precisely at twelve o'clock the ex-officios who assemble only on such occasions, the landlord elements with their serf-drivers cudgelling on their respective contingent of white slaves, with a few subs lurking in the distance, assembled at the dispensary, a dingy house measuring about 10 by 12 feet, and where there was scarce standing or sitting room for the committee. The Royals were drawn up in military array opposite the place, while the Neale and Kilmaine *Loyals*, armed with blackthorns, formed an outer cordon, and giving expression to their indignation by an occasional groan or cheer as they considered it was merited by the members of the committee who passed them by. It would be amusing if it were not so ludicrously revolting to see these poor serfs lurking round corners, their very countenance betraying them, their pull at the hat, and down on all fours, Spaniel-like at seeing their agent or master."

If there be any truth in the assertion frequently made that the Irish people is as yet unfit for the exercise of political privileges, there is a still greater force in the statement that the class of the Irish population of which boards of guardians and dispensary committees are constructed is unfit for local self-government. In Ireland there are two religions, and, *ergo*, two political creeds, nearly equally balanced in respect of influence, and most unhappily and most unnecessarily engaged in a perpetual struggle for the upper hand, a struggle which is rendered more acrimonious by the impulsive temperament of the people. Before this all-absorbing contest, all better feelings and larger ideas give way in the minds and hearts of those who have never been educated to think calmly and to decide without prejudice, or who have inherited from their progenitors of "the good old times" the unwillingness and incapacity to grant fair play and equality of privileges to their neighbours. Those who live outside the Green Isle can hardly realise the intensity of this most pitiful and calamitous antagonism between well-meaning but unthinking people, but when we say that the passage quoted above is nothing more than the reflex of a bigotry which exists in many of the 893 dispensary districts, and of the 163 unions in Ireland, it will be understood why we have declared that the Irish committeemen and guar-

Digitized by Google

dians are as a rule unfit for local self-government, and that it is a disastrous mistake to submit to their decision any matter out of which a party contest can possibly be made.

Though we have been obliged by our text to indicate a particular religion and a particular political creed, we draw no comparison less favourable to those who profess that religion or creed than to those who hold the opposing forms of bigotry.

There are many dispensary districts in Ireland in which the opposite side are just as intolerant and as grossly forgetful of the duty with which they have been entrusted as is the *Tuam News*, and each day's newspaper illustrates but too forcibly the fact that a large section of the "local governors" who are set over the administration of medical poor relief, care not enough for their public duties to attend the business meetings of their board or committee, but will come *en masse* and with servility to the politico-religious whistle, on an occasion when the affair in hand is to decide whether the charwoman employed to scrub out the dispensary hut shall be a Protestant or a Catholic, or to fix the method by which some poor, unconscious, starveling infant is to be allowed, if it survives its miserable babyhood, to worship its Maker.

For such a state of things there is one and only remedy —education. When, if ever, the mass of the Irish middle classes can be brought to believe that which all civilised nations hold, that the fitness of a person for any position whatever is the outcome of that person's moral, educational, and social qualities, and of special efficiency for the duties for which that person is required, then, and not till then, will Ireland be fit for self-government. To the attainment of such a frame of mind should all real patriots strive. Such a time is dim in the long vista of hope deferred; but it will come some time, and then, and not until then, will the average Irish dispensary committeeman be fit to vote for the average Irish dispensary doctor.

The *Tuam News* tells us that, "casting aside all other motives" (including, of course, regard for the sick poor, all regard for fairness towards the competitors, and every idea of honestly selecting the most competent and most efficient officer), "the member of a committee is strictly and conscientiously bound to secure, as far as in him lies, by vote as well as by his influence, the return of his own co-religionist."

Abominable dogma! Monstrous prostitution of a solemn trust! Vile forgetfulness of duty! And yet it is so in very many Irish districts, where magnates, blinded by the prejudices of their fathers and grandfathers, condescend to copy the bigotry of hedge shopkeepers and con-acre farmers in other places. We epitomise our argument in the assertion of the fact that, in Poor-law medical elections professional competency is but an insignificant fraction of the influences which decide the matter, and that it is a miserable legislative error to entrust the interests of the dying pauper to any class which considers itself "strictly bound, casting aside all other motives, to give vote and influence to" the man who adopts his own method of saying his prayers.

METHOD OF MEDICAL EDUCATION.—II.

THE CONTINENTAL SYSTEM.

THE system of professional study existing on the Continent, as described by Drs. Herman and Beigel in the Appendix to the Medical Council's Minutes, is worthy of being set side by side with our own.

The German universities are the real schools for the pursuit of special study, and not mere examining boards for testing knowledge obtained elsewhere. A university consists of four faculties, viz., Divinity, Law, Medicine, and Philosophy. Each faculty is governed by a dean, the university itself by the rector. The body of teachers consists of the ordinary professors ("ordentliche professoren"), extraordinary professors, lecturers ("privat docenten"), and lectors. Any student who has completed his regular course of study, and has graduated by examination in one of the faculties, may become a "privat docent" of one of the subjects included in the curriculum of that faculty, provided he receives the consent of the senate of the university, consisting of rector, deans, and university judge (universitatis-richter). The body of "privat docenten" constitute a most important and peculiar feature in the university life in Germany, and as their success depends entirely upon their own abilities and industry, they are constantly stimulated to activity. The extraordinary professorships are usually given to distinguished "privat docenten" whose services the university authorities desire to retain and recognise, but for whom no chairs are vacant. Lectors are men, either graduated or not graduated, lecturing upon subjects which do not come within the university curriculum, and for which no chairs exist. The appointment of the ordinary professors is vested in the members of the faculty, but subject to confirmation by the Government. They are always certain of a moderate competency by virtue of the endowment belonging to the chair; but they also receive the fee paid by students, and this may, in some cases, amount to a very considerable sum. Professors of the more purely scientific branches of medical study—such as anatomy physiology, &c.—are not expected to undertake private practice.

A student in possession of a certificate of maturity on entering a university, matriculates. This consists merely in placing his name upon the books, and signing the laws. He thus becomes a "civis academicus," and ceases to be subject to the civil law, acknowledging allegiance only to the laws of the university. After he has declared what branch of study he intends to pursue, no restriction whatever is placed upon him, and he is left entirely to his own devices. For convenience, however, a printed paper is placed in the hands of the medical student, stating what the senate considers to be the best mode and order in which medical science can be studied. It must be remembered that this scheme is merely offered as advice, and the student is in no way obliged to follow it; the majority of students, however, naturally follow more or less closely the plan marked out by the authorities.

The term of study is required to extend over four years, and the student is obliged to be inscribed for at least two courses of lectures and one course of dissections in each session (such courses of lectures must, however, extend over the whole session), but no control whatever is exer-

Digitized by Google

cised to determine whether he attends the lectures or not.

In France there are three Faculties (Facultés) which have the right to confer medical degrees—viz., Paris, Montpellier, Strasbourg. To these three Faculties are attached twenty-five preparatory schools (école préparatoire).

The teaching body consists of twenty-seven professors in each Faculté, and a number of agrégés, the latter forming a body of assistant professors, doing the work of the department in the absence of the principal, and being largely employed in private teaching, they correspond in some measure to the privat docenten of the German universities. Before any one is appointed to a professorship, the greatest care is taken to ascertain his ability as a teacher. There is, however, seldom much difficulty in doing so, as it is almost necessary for him to have served for ome time as agrégé before his promotion.

The medical men are divided into graduated ("gradés") and non-graduated ("officiers de santé"); the latter qualification is rarely taken, except by persons in a lower station of life, by chemists and druggists, or by holders of foreign degrees, who do not wish to graduate in France. We shall, therefore, treat more fully of the gradés, as representing the ruck of the medical profession in France.

The curriculum extends over four years, an inscription being made every three months, so that sixteen inscriptions are required in the entire period. Before entering the Faculté the diploma of "Bachelier-ès-Lettres" must be obtained by the student by one of the "Facultés des Lettres" in France, of which there are seventeen.

All lectures, as well as all practical work, required for the degrees are gratuitous, but fees are paid by the students at each inscription, and the cost of the entire education is therefore not much less than it is in Germany. The private instruction given by an agrégé must, of course, be paid for.

Notes on Current Topics.

Workhouse Visiting.

Can we picture to ourselves a workhouse ward, with its long row of beds occupied by humanity in all forms, in various stages of human suffering, as being anything but a sad and depressing sight? When to the above are added the want of skilled and efficient nursing, the absence of books, papers, illustrated periodicals, or of pictures on the walls to relieve the eye, the mind, the imagination; the utter separation from the outer world, and thus a virtual closing of the doors of hope; the absence of any sympathetic voice to utter a word of cheer and comfort, we have a still more gloomy picture, and one which must appeal to the better feelings of all who are interested in the waifs and strays of human life.

This picture is true in nearly all its details, though there are a few workhouse infirmaries where it does not apply. We notice with pleasure that there is a revived interest in our workhouses, and that the visiting of these institutions is again attracting the attention of some of our leading philanthropists. We do not know of work more needed or more charitable, and we are quite certain that if the guardians were to consider the question, apart from the official influence of interested obstructives, they would recognise the great advantage which would accrue from an organised system of lady visitors. All medical officers of poorhouses are in favour of this scheme: this of itself speaks volumes. We need not say that the sick poor in those workhouses where it has been tried look upon their visitors as angels of mercy, and the ladies are always treated by them with all possible respect.

Testimonial to Dr. Andrews of Belfast.

A meeting was held last Saturday week for the purpose of inaugurating a movement to establish some permanent memorial of the distinguished services rendered to science and education by Dr. Andrews, Vice-President of the Queen's College, Belfast, for many years, in connection with his retirement. Resolutions were adopted that the memorial should consist of a bust or portrait to be placed in the College, and secondly, of a prize or scholarship to be founded. A committee has been appointed, with the President of the College as chairman, to carry out the necessary steps. Dr. Andrews was formerly Professor of Chemistry to the Queen's College, Belfast, and as a chemist has been the discoverer of more than one matter of great importance in that branch of science; among others, we may mention that of the true continuity of the condition of matter in its transition stage from the gaseous to the liquid.

Death of Prof. A. Chevalier.

The oldest member of the Académie de Médecine, M. Chevalier, has just died in the eighty-seventh year of his age, having been elected in the year 1824. He had been also a Professor of the Ecole de Pharmacie, and was editor of the *Journal de Pharmacie* for many years. He was one of the most active of the members of the Conseil de Salubrité, and few men have done more than him in originating improvements in public hygiene, especially as regards alimentary substances. His reports to the Academy on mineral waters, secret remedies, and various hygienic subjects, and his articles in the *Annales de Hygiène*, constitute an enormous mass of writing of great practical utility.

The Tenancy of their Offices by Medical Council Representatives.

In our note of the proceedings of the Executive Committee, which appears in another column, we record the fact that Drs. Smith, Leet, Storrar, Humphry, Andrew Wood, and Rolleston have been re-elected by their respective constituencies.

To this piece of routine business more interest attaches than may appear at first sight, from consideration of the fact that, whereas Drs. Leet, Smith, Storrar, and Humphry were re-appointed for one year only, Drs. Wood and Rolleston have been granted leases of their offices for three and five years respectively. It strikes us that these long tenancies are highly inexpedient, and that in the pending revision of the Medical Acts words should be introduced having for their object to make the appointment annual.

The profession generally is probably unaware that, once a representative has been appointed by a licensing body, that body loses all direct control over his acts for

Digitized by Google

the period of his appointment. No matter what course he may see fit to pursue, even if he should wholly misrepresent the policy of his College and adopt a line of action diametrically opposite to his instructions, there exists no power whatever under the Act, either in the Licensing Body or in the General Medical Council, to declare his office vacant. His removal from office must be his own act, and his seat can only be vacated (under clause 8 of the Act) "by his addressing a letter to the President of the General Medical Council;" moreover, the law does not authorise the appointment of any person in his place, except "upon his death or resignation." Thus if, unhappily, any of the representatives who have been appointed for terms of years were to become incapable by aberration of mind, by severe illness, or by paralysis, of writing his letter of resignation, he must continue to hold office until the lapse of his term of appointment, and, *pro tanto*, the body which he should represent must remain voiceless in the deliberations of the Council.

Our objection to long tenancies is not a visionary one, for we are aware, as a matter of fact, that some years since the representative of a licensing body *did* retain his seat long after he had become obviously incapable of doing justice to the interests of his College; and although the Council of his College adopted a deliberate resolution suggesting to him the virtue of the practice of resignation, he positively refused to vacate his office, and continued to hold it until its lapse. It is, we admit, very desirable to guard the independence of the members of the Council, and to protect them from over-dictation on the part of any majority which may hold power in their elective body, but we submit that as long as members take their seats as representatives, it ought not to be possible for them with impunity, if they should so wish, to misrepresent their constituencies.

Military Medical Millinery.

We believe that the tailoring department of the War Office, which is always well looked after, whatever else may be neglected, is at work upon the army doctors' clothes, and the profession is to be wheedled into the Queen's service by the enticement of a new dress. "The forage cap is to be relieved of the unsightly badge and a gold and black band substituted, of black leather for surgeons, and with gold embroidered edge for the higher ranks; the peak will he sloping. The collar of the patrol jacket will be modified and made more dressy; and the black pouch and sword-belts will be discontinued. Brigade surgeons will wear the braided frock-coat as at present worn by deputy surgeons-general.

We presume that there must be people whose souls are moved by the anticipated bliss of a "gold and black band," or a "dressy" jacket. If so, we wish them joy of their pretty new "things," and we hope that the great-minded patriotism, intelligence, and originality of the gentlemen who have solved the unpopularity of the Army Medical Service by the aid of a new jacket and cap will not go unrewarded. A C.B. should be the least recognition of their services.

Health Resorts.

The unpropitious nature of the present season in places usually considered to enjoy perennial summer, suggests the propriety of advising patients to make trial of localities nearer home than are the spots generally recommended. At Cannes, which is a favourite winter refuge, for the past few weeks the weather has been no improvement on that experienced at home, and the advantages of a residence in it have been therefore reduced to a minimum. In view of this it seems advisable that trial should be made of certain of the sheltered villages on the coast of Devon. In many of these, particularly along the Exmouth coast line, the most genial weather has prevailed of late, and at a time when the cold and discomfort have been at the greatest, in situations farther north. The fashionable predilection in favour of foreign towns is much to blame for many deaths that might possibly have been prevented for a time, had the attention of the invalids been drawn to the possibility of discovering a genial abode in their own country.

The Bader-Gordon Case.

The decision in the Court of Common Pleas last week by which Mr. Bader, the oculist, recovered £23 2s. as fees for the performance of an operation on the defendant in the case, must commend itself to all who rightly comprehend the facts. The suggestion made by the jury that the whole possibilities of the operation and its consequences should have been explained to the patient is a sensible comment on the evidence, but it is difficult to understand how, in any event, a legitimate objection could have been raised against the payment of fees for services rendered. Were the principle once ceded that "no cure, no pay" must influence the conduct of patient to medical attendant, then the greatest confusion would result in the inter-relations of the two classes; and were it for no other reason than this, it is satisfactory to find that the obligations of the two contracting parties have been correctly appreciated in the recent trial. Into the question of the correctness or otherwise of the operation performed we do not enter, purposely, save to regret the exhibition of conflicting opinions presented to the public. It is far from edifying, this differing of experts in open court, and on matters concerning which the public is very naturally surprised that two opinions *can* be held. The evil that is done is due to the incompetence of the lay mind to comprehend the data on which conclusions are based. But for this reason the rarest occasion should be afforded for the exercise of wonder.

The Executive Committee of the General Medical Council

held its promised meeting on Friday, 28th ult. Its preliminary work was the reception of the official notifications of the re-appointment of Drs. Leet, Andrew Wood, Aquilla Smith, Storrar, Rolleston, and Humphry, as representatives of their respective colleges and universities. Upon this subject we have made some observations in another column of our present issue.

The Committee was next engaged upon consideration of a correspondence with the Irish Branch Council, and upon a legal opinion submitted by them as to the practice adopted

Digitized by Google

in the London office of registering additional qualifications, and making alterations in the Register, without their being effected, in the first instance, by a Branch Registrar. The registration of additional qualifications represents, of course, a certain amount of income to the Branch Councils, and the Irish Council is advised by the Solicitor-General for Ireland that "it is both the intention, and in accordance with the true construction of the Act, that the additional qualification should be registered, in the first instance, in the local Register." As to erasures and alterations of address the advice is not so decided, but the Irish Branch Council, in their letter to the Executive Committee, suggest that the General Council should at once make rules for having this work done in the branch offices.

Upon consideration of these communications the Executive Committee decided to submit them to their lawyers, for the information of the General Council.

The Committee next received from the Scottish Branch an important digest of the views of the Scotch bodies on the subject of preliminary education, to which we intend to refer in a future issue of the *Medical Press*. The Irish Branch Council forwarded nothing but the following characteristic resolution :—"That, taking into consideration the great diversities of opinion among the Licensing Bodies on the subject of Preliminary Education, and the impending amendment of the Medical Act (1858), the Branch Council believe that the question of Preliminary Education may be postponed for future deliberation."

Considering that the only reasons for the inquiry submitted to the Irish Branch Council were that "great diversities of opinion" existed, and that "the amendment of the Medical Act is impending," it seems a little unreasonable that the Branch Council should quote these circumstances as reasons why they should give no answer.

But we suspect that the real fact is, that the Branch Council thought that, on the subject of Irish preliminary education "least said" would be "soonest mended," and that they had better leave the raising of the storm to the General Council.

The remainder of the session of the Committee was occupied by consideration of letters respecting registration of British diplomas in Canada, concerning standard apothecaries' weights and measures, and the replies to the ophthalmic surgeons' memorial, to which we shall refer in an early number.

Irish Prison Surgeons.

The proceedings of the new Irish Prisons' Board are certainly not calculated to inspire the public with confidence in its administrative capacity. On the first day of April (ominous date !), 1878, the Board was born, and since then it has had supreme command of the entire prison system of Ireland. We are now close upon the second year of its tenure of office, and the net result, as regards the medical officers under the department, has been to create an embroglio utterly bewildering and incomprehensible. Not a sixpence has yet been paid to these officers for their two years of service, and no one knows on what terms they hold their offices, or, indeed, whether they hold them at all. The labour of the prison surgeons has, contrary to the express provisions of the Act, been greatly increased; the salaries have been first fixed at a ludicrous amount, and then again practically revoked, and both the Department and its medical officers are at sea as to what they are to receive for their two years' work, and for the future. The apothecaries have been ousted in direct violation of the rights reserved to them by the Act, and cannot tell whether they are to be reinstated, compensated, or pensioned. Finally, we are told that the muddle created by Mr. Charles Bourke has been submitted to the disentanglement of a Departmental Committee, but even of this tribunal, its members, its *locus*, or its powers, no one knows anything. There is, indeed, some uneasiness lest this Committee should prove to be a phantom or a ruse to keep the doctors quiet until their indignation blows over, or until the general elections have been held.

The new department has undoubtedly earned for itself the distinction of having distanced all other Government offices in the noble art of "How not to do it;" and unless the "Departmental Committee" comes to the rescue, we suppose the Tite Barnacle of the occasion, and the jaunty young Barnacles of the office will have it all their own way.

The Weather and the Death-rate.

The severe weather is beginning to show its effects most markedly in the rates of mortality throughout the United Kingdom. Last week the death-rate in the principal towns was :—Salford 18 per 1,000, Portsmouth 20, Norwich 21, Oldham 22, Edinburgh 23, Sheffield 23, Sunderland 24, Bradford 25, Hull 25, Glasgow 25, Leeds 26, London 27, Leicester 27, Birmingham 28, Manchester 28, Bristol 28, Nottingham 28, Newcastle-upon-Tyne 29, Plymouth 29, Brighton 30, Dublin 37, Liverpool 37, and the highest rate 44 in Wolverhampton. The annual death-rate from the seven principal zymotic diseases ranged from 0·6 in Norwich to 6·1 in Dublin, and 6·6 in Liverpool. Scarlet fever showed the largest proportional fatality in Newcastle-upon-Tyne, Sunderland, Dublin, and Sheffield; measles in Leeds, Nottingham, Plymouth, Birmingham, and Liverpool. Diphtheria caused 15 deaths in London, 4 in Liverpool, 2 in Birmingham, and 2 in Manchester. Five deaths were referred to fever in Leeds, 4 in Sheffield, and 31 in London. Five more fatal cases of small-pox were recorded in London, 9 in Dublin, but not one in any of the other large towns. The deaths from diseases of the respiratory organs rose last week in London to 612 from 190 the previous fortnight, a result almost wholly attributable to the severe cold.

Bequests to Medical Charities.

Hospitals, dispensaries, and other institutions in which the profession is more or less interested, have received quite a shower of blessings from wills and gifts from the charitably-disposed during the past few days. An eccentric old lady who died last week has left £10,000 to build a hospital at Hounslow, and the remainder of her wealth is to go towards endowing the said hospital, after her will has been duly administered in other particulars. She also bequeathed £100 to the Moorfields Ophthalmic Hospital, and a like amount to her medical attendant, Dr. Tyler Smith. The Guest Hospital, Dudley, comes in for the handsome bequest of £10,000, under the

Digitized by Google

will of Mrs. Charlton, of Dudley, the Dudley Dispensary £1,000, and the Midland Eye Hospital £300. The City of London Hospital for Diseases of the Chest, the Truss Society, and the Royal Hospital for Incurables are recipients of considerable legacies under the will of Miss M'Kenzie, late of Lower Clapton.

The following medical charities receive bequests of £1,000 each under the will of Caroline Batty, of Grove End Road, St. John's Wood, the City Orthopædic Hospital, St. Mary's Hospital, the Convalescent Hospital for East London at Snaresbrook, the Charing Cross Hospital, the Brompton Hospital for Consumption, &c., the Earlswood Asylum for Idiots, St. Luke's Hospital for Lunatics, the Middlesex Hospital, the London Hospital, the Metropolitan Convalescent Institution at Walton-on-Thames, the Metropolitan Free Hospital, the Cancer Hospital, the City of London Hospital for Consumption, the Royal Hospital for Incurables, and the National Hospital for the Paralysed and Epileptic. The following receive £500 each — Queen Charlotte's Lying-in Hospital, the General Lying-in Hospital, the Royal National Hospital for Consumption at Ventnor, and the Royal Medical Benevolent College. The Convalescent Hospital, Belfast, has received £600 from Lady Johnson. Mr. W. Crawford has given £200 to the Home for Incurables, Cork. The Belfast Royal Hospital will receive nearly £3,000 under the will of the late Dr. Bryson, of Coalisland.

The Water Supply of London.

A WELL-TIMED article from the pen of Mr. Torrens, M.P., appears under the above heading in the current number of *Macmillan's Magazine*. The subject is a matter of as much importance to health and life as the air we breathe. On reflection, then, it may appear strange that we should have to appeal to the Legislature to assist the largest and most advanced city in the world in securing a pure and bountiful supply of water in a state fit for domestic uses, and at a price that shall be both fair and reasonable. The grievances of which Londoners have, at the present moment, just cause of complaint, are, Mr. Torrens believes, threefold :—1, a want of constant supply to each household ; 2, want of practical check on the price charged ; 3, want of facilities for extinguishing fires. There is, however, another grievance of even greater moment, the want of a potable water from a pure source, and entirely free from any danger of contamination or pollution, as is now the case in water taken from open watercourses or tidal rivers.

The Companies no longer offer opposition to the constant supply system, because they have discovered it is to their advantage. There is less waste of the commodity they sell when careless people are exposed to the constant danger of being drenched or drowned by omitting to turn off the water-tap. There is more difficulty in getting the middle classes to adopt the system because of the exorbitant demand made by the plumber, and the danger, when the work is slovenly done, of the pipes giving way in the first frost. The estimates for making the necessary alterations are found to vary from ten shillings to as many pounds. On this account it is difficult to persuade even the well-to-do to abandon the storage of the house supply in cisterns. Water, like milk or mutton, is intensely susceptible of taint, even without direct contact with what is decaying or decayed. It is not capable of being kept pure for many hours in an impure atmosphere, as it rapidly absorbs the foul air from the sewer, or the respired air of multitudes of human beings, and of the four-footed creatures around or near it. In the dwellings of the poor the water-butt or cistern is almost invariably to be found close to the water-closet, and in lodging-houses it is no one's duty to see that the water-cistern is ever cleansed. Constant supply is the sole remedy for this evil ; it will also diminish the risk from fire, as it will give increased facility for putting out casual fires ; but it will not in the slightest degree improve the quality of the drinking water, nor will it diminish the price, or regulate the tax laid by the Companies upon the householder.

The Home Secretary promised at the close of last session that ministers would during the recess take the whole subject into consideration, and be prepared to submit some general scheme to Parliament. He, no doubt, has so far fulfilled his promise, for a fortnight ago we were able to state that he had given notice to the several water companies of his intention to absorb them, and place the water supply of London in the hands of a central board.

It is acknowledged that the Metropolitan Board of Works is already overweighted, and cannot undertake a responsibility so great as this would entail, and it is therefore the Home Secretary's intention to establish a new authority, but of the successful working of which Mr. Torrens, in common with ourselves, has his doubts. Very many reasons can be urged against centralisation. The details of deficiency and defect are inexhaustible, varying with every condition of domicile and employment—in some instances with every locality, and by their accumulation proving incontestably the imperative need of local tribunals, easily accessible, for the settlement of controversies continually arising. Why should not a great borough on the banks of the Thames have the same right of controlling its gas and water supply as a great borough at the mouth of the Mersey, or a large provincial town in Lancashire ?

A central board for the regulation of either gas or water would undoubtedly prove a failure, because, as Mr. Torrens says, "it must be irretrievably swamped by the multiplicity of details and the confusion of interests with which it would have to deal."

A central board means a big job—a chairman or staff of commissioners, with inspectors and clerks to dictate to four millions of people, and to a certainty, to make the whole thing, so far as the public are concerned, a dead failure.

THE rates of mortality in the principal foreign cities, according to the most recent weekly returns were—in Calcutta 26, Bombay 37, Madras 35 ; Paris 27 ; Brussels 27 ; Amsterdam 20, Rotterdam 24 ; The Hague 23 ; Copenhagen 40 ; Stockholm 19 ; Christiania 15 ; St. Petersburgh 31 ; Berlin 21, Hamburg 29, Dresden 18, Breslau 23, Munich 32 ; Vienna 25 ; Buda-Pesth 33 ; Rome 32, Naples 27, Turin 27 ; Alexandria 34 ; New York 23, per 1,000 of the populations. Small-pox caused 29, and enteric fever 24 deaths in Paris.

Digitized by Google

Invitations have been issued by the Lord Mayor of London for the usual annual meeting, on Thursday next, at three o'clock, of medical men and clergymen interested in the Hospital Sunday Fund, for the purpose of electing council and fixing date of collection for 1880.

The Chief Secretary for Ireland has been pleased to appoint William Thornley Stoker, Esq., M.D., to be Inspector for Ireland under the Act 39 and 40 Vict., cap. 77, sec. 10, in succession to the late Registrar-General for Ireland, Dr. Malachi Burke.

The Rev. Henry Stebbings, D.D., F.R.S., Rector of St. Nicholas Cole Abbey, E.C., has been presented with a handsome silver salver, in recognition of his long and devoted services as Chaplain to University College Hospital, from the foundation in 1834 until his retirement in 1879.

A correspondent reminds readers that Colonel Leet, who on Tuesday last received the Victoria Cross from the hands of the Queen for saving the life of a brother officer under circumstances of extraordinary difficulty and danger, and after he himself was seriously injured, was at one time on the eve of entering the medical profession, and was for three years a pupil at the Richmond Hospital, Dublin, but just as he was about to qualify he was offered a commission in the army and accepted it.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

Glasgow Medico-Chirurgical Society.—At a meeting of this Society, held in the Faculty Hall, St. Vincent Street, on the 12th inst., Dr. Hugh Thomson presiding, Dr. McCall Anderson read a paper on the Climatic Treatment of Consumption, with special reference to a visit to Davos Platz; and he showed a patient who had recovered from galloping consumption, and read notes of the case. Dr. Coats opened the discussion by giving some personal experiences of Davos. Dr. Charteris very humorously and effectively narrated his experience of the treatment of consumptives at Frankenstein. A good deal of the popularity of this place, he thought, was due to the fact that a consulting physician in Frankfort had a commercial interest in the pension. Most of the patients here took brandy—half-a-bottle a day. Those who were not likely to get well were sent away, and there was a chance of recovery for those who took the brandy, none for those who did not. He described the patients as very cheerful, and suggested that this system of treatment ought to be introduced into Scotland, the present time certainly being opportune, owing to the Cimmerian darkness in which we are enveloped. He considered the use of the term "galloping consumption" as applied to Dr. Anderson's case decidedly "horsey," and likely to mislead the public. If Dr. Anderson had succeeded in arresting the progress of a case of acute tuberculosis of the lung, he had accomplished what no other person had hitherto achieved. Dr. Charteris seemed to express the feeling of the majority of the meeting. Dr. Perry made some remarks likewise deprecating the use of the term applied by Dr. Anderson. He was followed by Mr. Reid, who spoke in a similar strain. Consumption, according to him, meant tuberculosis, and if we were to admit the term here applied, we must acknowledge the other comparative degrees; then we would have "the walking consumption, the trotting consumption, and the galloping consumption." He considered Dr. Anderson's case as one of pleuro-broncho-pneumonia. Dr. Martin narrated certain cases of recovery from phthisis. Dr. McPhie referred to the thoroughly exploded notion that an immunity from consumption exists in some of the Hebrides, and was understood to say that in certain cases consumption appeared when better houses were built, particularly, he noticed, with slated roofs. Dr. Anderson, in reply, stated that he did not allege that this case was one of tubercular consumption, and that it was impossible during life (and very difficult after death according to Dr. Coats) to diagnose the tubercular from the non-tubercular phthisis. It is surely high time that there was some consensus of opinion as to the term "consumption." There can be no doubt that hitherto it has been associated in the minds of the great bulk of the profession with the deposition of tubercular matter, and that such cases were regarded as almost necessarily fatal, in what has been popularly called the "galloping form." That the lung tissue may break down in consequence of inflammation is undoubted; but cases of this description have never been regarded as "consumption." The application of the term "galloping consumption" in such cases as Dr. Anderson's has the appearance of *ad captandum vulgus*, and ought to be abandoned, or rather ought never to have been employed.

Matriculation of Medical Students at the University of Edinburgh.—Out of the gross number of 2,510 students who matriculated at the University of Edinburgh this session, no less than 1,138 are students of medicine, viz., first year, 337; second year 277; third year, 257; and fourth year, 267. This is an increase of 96 students of medicine as compared with last year.

Registrar-General's Return for November.—The monthly return of births, deaths, and marriages states that there were registered in the eight principal towns in Scotland, during November, 1879, the births of 3,182 children, of whom 1,625 were males and 1,557 females. The deaths of 1,833 persons were registered in the eight towns during November, of whom 938 were males and 895 females. This is the smallest number recorded for any month of November since that of 1855, and, allowing for increase of population, is 880 under the average for the month during the past ten years. A comparison of the deaths registered in the eight principal towns shows that during November the mortality was at the annual rate of 15 deaths per 1,000 persons in Leith and in Greenock, 16 in Dundee, 17 in Edinburgh, 18 in Glasgow and in Paisley, and 19 in Perth and in Aberdeen. Of the 1,833 deaths, 757, or 41 per cent., were of children under five years of age; in Perth 27 per cent. of the persons who died were under five years of age; in Paisley 29; in Greenock 31; in Dundee 37; in Aberdeen 40; in Edinburgh 41; in Glasgow 44; and in Leith 56 per cent. The miasmatic order of the zymotic (epidemic and contagious) class of diseases proved fatal to 274 persons, constituting 14·9 per cent. of the whole mortality. Fever caused 40 deaths, of which 13 were tabulated as typhus, 26 as enteric, and 1 as simple continued fever. The most fatal epidemic was whooping-cough, which caused 60 deaths, or 3·3 per cent. of the whole mortality. Of these 13 occurred in Aberdeen, being at the rate of 8·0 per cent. of the deaths in that

Digitized by Google

town. The deaths from inflammatory affections of the respiratory organs (not including consumption, whooping-cough, or croup) amounted to 421, or 23·0 per cent. Those from consumption alone numbered 213, or 11·6 per cent. Four deaths were ascribed to the direct effects of intemperance.

KILMARNOCK FEVER HOSPITAL AND INFIRMARY.—The annual meeting of the subscribers to this institution was held on the 10th inst., Provost Sturrock presiding. The annual report showed that 488 cases had been treated during the year, being 62 in excess of last year. The funds were declared to be in a very satisfactory condition. A special vote of thanks was accorded to Dr. Borland, the Surgeon to the institution; and Dr. Macfarlane was elected a Consulting Physician.

HEALTH OF EDINBURGH.—For the week ending December 6th, the mortality of Edinburgh rose from 85 to 92, and the death rate is 22 per 1,000. Chest diseases have proved unusually fatal in old people in all parts of the city. The zymotic mortality continues low.

EDINBURGH UNIVERSITY COURT.—At a meeting of the Edinburgh University Court held on the 8th inst., *inter alia*, J. O. Affleck, M.D., F.R.C.P. Edin., was recognised as a teacher of medicine in Edinburgh, whose lectures on the Practice of Physic should qualify for graduation in medicine in the University, in terms of Ordinance No. 8, sec. vi. Further, the fees for the classes of Operative Surgery and of Practical Gynæcology were raised from £2 2s. to £3 3s.

GLASGOW ASSOCIATION FOR PROVIDING TRAINED NURSES.—The Association for Providing Trained Nurses for the West of Scotland held their fourth annual meeting in the Religious Institution Rooms, Glasgow, on the 10th inst., Dr. A. B. McGregor presiding. The report stated that the institution was in a highly prosperous condition. During the past year five nurses had made 12,179 house-to-house visits. The cases overtaken in this manner numbered 705, and other 33 patients had been supplied with nurses permanently at merely nominal fees or gratuitously. While there had been less demand for nurses in the past few months, they were very busy, and went greater distances than before in the earlier part of the year. The income amounted to £1,584 3s., and the expenditure to £1,142 2s. 8d.

ROYAL SCOTTISH ACADEMY.—On the 10th inst., in the Life School of the Royal Scottish Academy, Professor Turner, Honorary Professor of Anatomy to the Academy, gave the first of two demonstrations from the living subject. There was a large attendance of students, the President and several members of the Academy, and the Hon. Bouverie F. Primrose being also present. At the close of a most interesting lecture, which was followed with close attention, the President conveyed to Professor Turner the thanks of the Academy and of the students.

HEALTH OF HILLHEAD.—The report of the medical officer (Dr. Christie) of this burgh has just been issued. It states that during the month of November 16 births and 5 deaths were registered as having occurred within the burgh of Hillhead, being at the annual rate of 29·54 births, and 9·23 deaths per 1,000 of estimated population. Of the births 10 were males and 6 females—13 legitimate, and 3 illegitimate. The causes of death were senile decay, congestion of the lungs, phthisis, whooping-cough, and croup, one case of each; the fatal cases of illness being all, with one exception, due to affections of the respiratory organs. The ages at death were 88 years, 66 years, the remainder being under 4 years of age. Isolated cases of illness from whooping-cough, measles, and scarlatina have occurred, but as yet no adequate cause has been ascertained.

GLASGOW ROYAL INFIRMARY.—AURAL SURGEONCY.—This appointment is at present vacant, owing to the resignation of Dr. Cassells. Doubtless there will be a keen struggle for the office. The reason assigned by Dr. Cassells is the somewhat serious one that he had been refused the assistance he deemed necessary for the proper conduct of his clinique. Surely this is an animadversion on some one in authority which ought to receive the attention of the directors. Following upon this resignation we understand that Dr. Cassells intends opening a practical class for instruction in diseases of the ear in "The Glasgow Dispensary for Diseases of the Ear," Buchanan Street, the course beginning on the 10th January, 1880.

DISPENSARY FOR DISEASES OF THE THROAT.—Dr. Foulis has commenced a series of lectures and demonstrations at this dispensary for senior students and practitioners. The lectures are to be delivered on the Saturdays of December, January, and February. We cordially commend this method of extramural lecturing, and hope to find the example thus set largely followed in Glasgow. We understand that Dr. A. D. Stewart has in contemplation the formation of a class for ear diseases, and Dr. Maclean, for throat diseases, at the Glasgow Public Dispensary.

ALLEGED CASE OF HYDROPHOBIA IN FIFE.—A domestic servant, about nineteen years of age, residing with her parents in the parish of Auchterderran, has died after a few hours' illness from what is believed to have been hydrophobia. For six months past she has been engaged as a domestic servant with an eminent physician in Edinburgh, and having received a few days to visit her parents, she reached home in what seemed her usual good health. She attended the church on Sunday with her sister, and after returning home she felt thirsty, and on procuring water she had some difficulty in swallowing it. When tea was tried she could not take it, and a pain, which during the day she had felt in her back, increased. A medical gentleman was called in. It was at first thought that she was suffering from some pulmonary complaint. Ultimately, however, the physician came to the conclusion that the symptoms were undoubtedly those of hydrophobia, and for several hours before her death the symptoms became more decided. It has since been found that about eleven years ago she had been bitten on the right thumb by a bull-dog, which her parents kept, and that the wound soon healed up. It has now been remarked that she felt considerable pain in the bitten hand some two years ago.

GLASGOW DEATH RATE.—During the past week an intense frost prevailed in Glasgow, and a very thick fog hung over the city; as a consequence the death rate has considerably advanced, being now at the rate of 25 per 1,000 per annum, against 17 in the preceding week, and 26, 24, and 23 in the corresponding periods of 1878, 1877, and 1876.

ABERDEEN FREE CHURCH COLLEGE.—Dr. M'Kendrick, Professor of Physiology in the University of Glasgow, has been selected to deliver this year's Thomson Lectures on Natural History and Theology in the Free Church College, Aberdeen. The first lecture, "On the Brain and the Senses," will be delivered on Friday. These lectures were begun last year, the then lecturer being Dr. Ludner Brunton of London.

HEALTH OF GOVAN.—Dr. Aitken, the Medical Officer of Health for Govan, reports that the total number of deaths registered in the burgh during the month of November was 64, being at the rate of 16·34 per 1,000. Consumption caused 11 deaths, bronchitis 8, inflammation of the lungs 6, diphtheria 2, measles 1, and scarlet fever 1.

HIGH DEATH-RATE OF STIRLING.—At the monthly meeting of the Local Authority at Stirling, held on the 8th inst., the medical officer's report for November was read, and showed that there had been thirty-eight deaths in the Parliamentary burgh, being at the rate of 30 per 1,000 per annum. Dr. McFadyen attributed the high mortality to the effect of the severe weather on the old and very young, no less than 10 deaths occurring of children under two years of age attributable to cold.

IRIDECTOMY AND SCLEROTOMY IN GLAUCOMA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I believe I was one of the first to call attention to the advantages of sclerotomy in the treatment of glaucoma. My experiences and the particulars of some of my earlier cases were given in a paper read before the Clinical Society on April 28th, 1876. The concluding words of that paper were:—"My own impression is that iridectomy will become every day less commonly employed, and that the operation I have described (subconjunctival sclerotomy) is the future remedy for the great majority of cases of glaucoma."

At the date of my paper few ophthalmic surgeons performed sclerotomy in this country. It is now much more commonly used, but not, I think, as you, sir, seem to imply in your editorial article, to the exclusion of iridectomy. According to my experience there are still cases of glaucoma in which iridectomy is the only reliable operation. They are—(1), the very acute cases; (2), those in which eserine fairly used fails to reduce tension; and (3), all those in which there has been precedent iritis with resulting synechiæ. I have in my recently-published work on "Eye-ball Tension" given illustrations of the value of both operations, and an instance in which, after the failure of sclerotomy, iridectomy succeeded. I am, however, still inclined to think, as I did in 1876, that iridectomy will never be so absolutely relied on as it once was as a remedy or glaucoma.

But, sir, this revoluion of opinion among ophthalmic surgeons, must not be looked upon as a retrograde movement. Sclerotomy is as much an operation of precision as iridectomy, and is a very different thing from a mere puncture of the sclerotic. It is true that in some cases a puncture of the sclerotic will relieve tension; so also will a puncture of the cornea, as was long ago pointed out by Gräfe himself; but neither of these expedients are reliable; whereas we have now abundant proofs that sclerotomy is a thoroughly reliable operation.

Hence, sir, I cannot but think that your strictures on ophthalmic surgery are hardly deserved. There is, however, another reason why sclerotomy can now be more often resorted to than formerly. We have now in eserine in a means of reducing tension of the eye-ball. We can, therefore, afford to wait even in cases that would appear otherwise urgent, and in the interval the choice of an operation can be made, without by delay endangering the integrity of the retina. But not only is this remedy (eserine) valuable before an operation. After sclerotomy we can by its means maintain a contracted state of the pupil, and can thus avoid a prolapse of the iris and its attendant dangers, the fear of which was one of the principal motives of excising a portion of this membrane in Gräfe's operations. I still hold, notwithstanding all that has been advanced against iridectomy, that we have in it the only reliable remedy for some of the worst cases of eye-ball tension, and venture to think that most ophthalmic surgeons of the present day would agree with me on this point.

I am, sir, your obedient servant,

W. SPENCER WATSON,
Senior Surgeon to the South London Ophthalmic Hospital, &c.

7 Henrietta Street, Cavendish Square, Dec. 10, 1879.

PROFESSIONAL MENTAL EPIDEMICS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Permit me to express my entire concurrence in the spirit of your leading article of last week on "Professional Mental Epidemics." In the history of medicine very many similar epidemics have been observed and placed on record, for they recur periodically amongst us. The discussion that followed the reading of Mr. Swanzy's paper on "Sclerotomy," at the Surgical Society, Dublin, is both significant and important, since it plainly denotes the change time has effected in the opinions of the leading ophthalmic surgeons with regard to the exaggerated views, at one time expressed of the value of iridectomy in glaucoma. You may perhaps remember that some fifteen years ago I enunciated what at the time was thought to be a very strong and decided opinion on the then increasing iridectomy proclivities for many and divers eye affections. The lapse of time and increasing experience has furnished no reason for the withdrawal of a single word I then uttered in condemnation of the mutilation of the eye. No physiological explanation, so far as I am aware, has been or could be offered of the supposed curative action of iridectomy, and therefore there has been an astute reticence observed by all its admirers this point, which has certainly saved them from an awkward dilemna. We remain, indeed, as much in the dark as we were when the operation was first imported into English eye practice, and "lauded as a panacea for all diseases of the eye." And I would venture to remind your readers of a fact that when Graefe first proposed and practised iridectomy he did so for the cure of recurring iritis, to diminish, as he said, "the intra-ocular pressure arising from the choroidal inflammation" which so often accompanied it. That his disciples looked upon this proposal as dangerous grounds to stand upon in defence of their practice is quite evident, as they very soon totally ignored the original proposal, and have persistently drawn all subsequent arguments and illustrations from a later one, namely, the employment of iridectomy for glaucoma. Subsequently, iridectomists, wishing to enlarge the scope of the operation, invented the ambiguous term "*glaucomatous affections.*" This term, as you imply, was apparently intended to include under one general heading divers different diseases, the only cure for which is cutting out a piece of the iris.

It is quite refreshing to find the majority of members of the Surgical Society of Dublin calling into question this very questionable operation, and it finds it broadly and emphatically laid down, "that there is no special advantage in abscising the iris, and that a simple incision made at the sclero-corneal juncture" is all that is necessary to relieve and cure glaucoma. This is exactly what I stated some twenty years ago, and it is high time "a public recantation of the iridectomy craze" took place, and that decided protest was launched against a form of "transient mental epidemic," which has led to the reckless practice in consulting rooms of cutting away a portion of the internal eye, with or without the consent of the patient, and has been the means of extracting a somewhat humiliating condemnation from an English judge and jury.

I am, &c.,

JABEZ HOGG.

1 Bedford Square, London, W.C.,
December 12, 1879.

Obituary.

DR. SOELBERG WELLS.

ONE more name to be added to the long death-roll of the current year, a year that has been unprecedentedly disastrous to the ranks of the medical profession. Soelberg Wells, M.D., F.R.C.S., died, on the 2nd inst., at Cannes, whither he had gone in search of quiet and a genial climate. As an ophthalmic surgeon, Dr. Wells had made for himself an enviable reputation, and was already, though comparatively a young man, favourably known in the department of ophthalmology in the great European centres of science. He enjoyed peculiar facilities for study, having been possessed of considerable means as a student, and thus able to spend a lengthy period at all the hospitals, at home and abroad, most worthy of attention. As assistant to Von Graefe, at Berlin, he acquired the great operative dexterity for which he was justly famed, and his appointment, in 1860, as clinical assistant to Mr. Bowman at the Royal London Ophthalmic Hospital, Moorfields, was an early recognition of his exceptional attainment in this direction. In 1867 Mr. Wells was elected to the post of Assistant-Surgeon to the institution he had already served for seven years; and this was followed in 1873 by promotion to the rank of Surgeon, this latter being held by him at the date of his death. In addition he was Ophthalmic Surgeon to King's College Hospital, and Professor of Ophthalmology in

Digitized by Google

the College attached thereto. As an author Dr. Wells will always be regarded as occupying a foremost place. His work on "Diseases of the Eye," already in a fourth edition, will retain its value for a long period; and another book on "Long, Short, and Weak Sight" has reached a fourth edition. The estimation in which the deceased surgeon was held, both by private friends and in the profession, will make his loss keenly felt on all sides, and particularly is it more grievous as coming close on the death of so many brilliant ornaments to the medical world. Dr. Wells had been long ailing, and finally succumbed to an ill-understood liver disease.

DR. COATES.

We record with regret the death of this gentleman, one of the most respected provincial practitioners in Ireland, who died last week at an advanced age. Dr. Coates qualified as a member of the London College of Surgeons in 1841, and as M.D. of the Glasgow University in 1845, and has occupied the position of medical officer of the Portumna Workhouse and Dispensary almost as long as those institutions have existed. In the county in which Dr. Coates practised, and in the adjoining counties, he was greatly respected, and his professional services were in great demand. With the *Medical Press* his connexion was coequal with his professional life, and his name appears in our columns as the contributor of valuable papers and cases of lithotomy, double popliteal aneurism, fracture of the skull and trephining, etc. Dr. Coates was one of the last and most creditable representatives of his generation, and his death has a melancholy interest for the men of his time.

DR. HENRY H. STEWART.

We have to record to-day the death of one of the oldest, and in some respects most remarkable, of our *confrères*, Henry Hutchinson Stewart, F.R.C.S.I., M.D. Univ. Edin., which occurred on the 3rd inst., at his residence in Eccles Street. Born in April, 1797, he had nearly completed his eighty-third year. One of a large family in not very affluent circumstances, his father having been an army chaplain, he began at an early age to contribute to his own support by acting as "page" to the Duchess of Richmond, an office conferred on him by the Duke soon after he was appointed Lord-Lieutenant of Ireland, in 1807, partly to relieve his father of so much of the expense of his large family, and partly because of the attractive personal appearance of the boy. He remained in connection with the Irish Court for several years, and only began to study for the medical profession late in life, having arrived at his thirty-third year before he obtained the licence in surgery of the Irish College and the M.D. of the University of Edinburgh, soon after which he was appointed surgeon to Killucan Dispensary, an office he resigned after some years, and came to reside in Dublin, at the same time acting as medical attendant to the School for the Sons of the Irish Clergy, then located in the old "Spa House" at Lucan, but he never took a prominent part in the actual practice of his profession, though always manifesting a warm interest, both in its science and its welfare. He was subsequently appointed Governor to the "Hospitals of the House of Industry." At that time there was connected with the hospitals an establishment for chronic lunatics, which was always a source of trouble and inconvenience. Most of the inmates were very old. Many of them had been so long there, that their friends and connections had died out, and they were forgotten, and were altogether dependent on the Government for their support; and their presence at the hospital was so inconvenient that the Government, some twenty-five years ago, proposed to Dr. Stewart to place them under his charge, and pay him at a certain small rate for their support. He accepted the offer, and taking the Spa House at Lucan, which had been vacated by the school, fitted it up as an asylum, and removed the inmates of the "Hardwick Cells" to that much more wholesome and appropriate situation. It was thought at the time that they would all die off in a few years, and as the building afforded accommodation for it, and to guard himself against loss, he admitted lunatic patients from the middle classes at rates of payment much below those of ordinary private asylums. Thus originated the Lucan Spa Asylum for Middle-Class Lunatics, and provision was made for the protection and treatment of a class of patients above the grade of paupers, but unable to pay for admission to private asylums, and for whom no provision whatever existed in Ireland. But the old chronic lunatics were not neglected. He fed them so well, and took such good care of them, that though it was calculated they would all be dead within from ten to twelve years, many of them are still alive and able to mourn the loss of their kind and watchful friend.

The benefits accruing to society from the Asylum for Middle-Class Lunatics became every day more developed, and so gratified the kind old man, that when warned by age that he should give up some of his active employments, he determined to make provision for its permanent maintenance. He was more than once offered large sums for his interest in it, but he refused to sell it. About this time the establishment of an institution for the cure and education of idiots was being agitated, and Dr. Stewart believed that such an institution could be advantageously added on to his asylum. Accordingly he waited on the Committee, and proposed to them to hand over the asylum to them, from which at the time he was receiving a very large income, and to give them a sum of £5,000, on the condition that they would maintain the asylum so long as they could make it a paying concern, and derive a profit from it, to be devoted to the support of this institution. Then he gave to the movement the impulse which enabled it to go on, and we have now the two institutions accommodated in the noble building that overhangs the banks of the Liffey at Palmerston, and which has been so appropriately named the "Stewart Institution."

An earnest, an enthusiastic, and a benevolent man, a large contributor to the Royal Medical Benevolent Fund and other professional charities, sparing of expense on himself, he was always ready to give money to relieve the wants of others, and especially to educational and other projects calculated to improve and elevate his fellow-man.

GALLANTRY OF MEDICAL OFFICERS AT CABUL.

We note with gratification the record—by the *Standard's* special correspondent—of conspicuous bravery on the part of Surgeon-Major Bourke and Surgeon Duke, on the occasion of the explosion of the magazine at Cabul. The instant that the explosion took place the whole of the troops in the neighbourhood were ordered to leave the place with all haste, and did so at the top of their speed, the other magazines being expected to explode at any moment. Permission to search the Upper Bala Hissar for wounded was refused, and the ambulance was ordered out of the fort. Surgeon-Major Bourke then took a small party of his corps outside the walls, in the rear of the magazine, and called for volunteers to climb the walls and search for the wounded in the ruins. He was joined by Surgeon Duke and one man, Private Bambridge, of the Ambulance. The walls were climbed, three wounded men were found and let down with ropes, the ammunition exploding violently all the time, and the big magazine being momentarily expected to go off. After a thorough search no more wounded could be found, and the party withdrew, not too soon, for almost immediately afterwards there was another explosion as violent as the

Digitized by Google

first, and several who had escaped the first explosion and were out on the plain, were killed or wounded.

DUBLIN PATHOLOGICAL SOCIETY.

In our issue of the 3rd inst. it was erroneously stated that Mr. Edward Hamilton was the outgoing President of the Dublin Pathological Society. It should have been Dr. William Moore. The error was not ours, for Mr. Hamilton's name appears both in the Irish and London Medical Directories for 1879, having been, of course, inadvertently furnished by the Hon. Sec.

Royal College of Surgeons of England.—The following members having passed the required examination for the Fellowship on Nov. 27th, 28th, and 29th, were, at a meeting of the Council held Dec. 11th, admitted Fellows of the College :—

Andrew, George, L.R.C.P. Lond., Englefield Green.
Hensman, Arthur, L.R.C.P. Edin., Harley Street, W.
Johnson, John, M.B. Melb., Melbourne.
Miller, Richard Shalders, M.B. Lond., Gower Street.
Robson, Arthur William Mayo, L.R.C.P. Lond., Leeds.

University of London.—The following are lists of the candidates who have passed the recent examinations :—

M.D. EXAMINATION.

Bury, Judson Sykes, B.S.	Nicholson, John F. (Gold Medal
Carrington, Robert Edmund	Paget, William Smith
Carter, William, LL.B., B.Sc.	Raine, George Rolph
Gadsby, John Topham, B.S.	Smith, Herbert Urmson
Glynn, Thomas Robinson	Uhthoff, John Caldwell
Hadden, Walter Baugh	

LOGIC AND PSYCHOLOGY ONLY.

Buchanan, Arthur	Lubbock, Montagu
Cattle, Charles Henry	Phillips, Sidney Philip
Edwardes, Edward Joshua	Silcock, Arthur Quarry, B.S.
Henderson, George Courtenay	Willoughby, Edward Francis

SECOND M.B. EXAMINATION.

MEDICINE.—*First Class.*

Smith, Robert Percy (Scholarship and Gold Medal)	*Mackern, George
Williams, Dawson (Gold Medal)	Gill, Richard, B.Sc.
	Pughe, Tiaeliesin Wilim Owen

Second Class.

Fuller, Thomas Warberton	Buckell, Arthur Edward
Boyd, James Stanley Newton	Hayle, Thomas Hahnemann
Bond, James William	Hine, John Edward
White, William Hale	

Third Class.

Herman, George Ernest	Hayward, Thomas Ernest
Taylor, Harold Gilbertson	

OBSTETRIC MEDICINE.—*First Class.*

Smith, Robert Percy (Scholarship and Gold Medal)	Gill, Richard
	Sheppard, Charles Edward
Fuller, Thomas Warberton (Gold Medal)	Herman, George Ernest

Second Class.

Gabb, James Percy Alwyne	Forsbrook, William Henry Russell
Hine, John Edward	

Third Class.

Williams, Dawson	Hayward, Thomas Ernest
Taylor, Harold Gilbertson	Boyd, James Stanley Newton
Buckell, Arthur Edward	Pughe, Tiaeliesin Wilim Owen

FORENSIC MEDICINE.—*First Class.*

Taylor, Harold Gilbertson (Gold Medal)	Hayward, Thomas Ernest
	Sheppard, Charles Edward

Second Class.

Pughe, Tiaeliesin Wilim Owen	Barling, Gilbert Harry
Sainsbury, Harrington	Hine, John Edward
Smith, Robert Percy	

Third Class.

Bond, James William	Maylard, Alfred Ernest
Hayle, Thomas Hahnemann	Colquhoun, Daniel

* Obtained the number of marks qualifying for a Gold Medal.

N.B.—The bracket indicates equality of merit.

B.S. EXAMINATION.

First Division.

Boyd, James Stanley Newton	Pughe, Rhinallt Navalaw ap Joan
Maylard, Alfred Ernest	

Second Division.

Bond, James William	Williams, Dawson
Jones, Thomas	

Second Class.

Jones, Thomas	Boyd, James Stanley Newton

Third Class.—Bond, James William.

NOTICES TO CORRESPONDENTS.

DR. J. DRYSDALE, Liverpool.—The lectures by Dr. Greenfield at the University of London, which commence to-day (Wednesday), will probably be published in book-form.

DR. HARRIS.—Yes, on Saturday last.

MR. COTTERELL.—We have already noticed it, in one of the November numbers.

"THE INVENTION OF THE IMMERSION PARABOLOID."

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I imagine that there must be some mistake which has given rise to the editorial opinion appended to Dr. Edmunds' long letter in your last issue to the effect that his paraboloid is a different and distinct invention.

It is a positive fact that he cannot possibly possess the one illustrated full size in my paper of 1856; he must, therefore, have submitted to your inspection a small *animalculæ cage* consisting of a tiny paraboloid which I presented to Mr. Crisp as a curiosity. Objects on the ordinary slides cannot be illuminated with this at all.

I trust that you will in justice insert this notice, as the comparison could not correctly represent the case.

Yours, &c.,

Dec. 11, 1879. F. H. WENHAM.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—As I am sure you will not sanction the use of the great authority of the *Medical Press and Circular* for the purpose of malicious defamation, I beg leave to state the following facts :—

A reprint of defamatory letters from Mr. John Mayall, jun., and Mr. F. H. Wenham, but with material portions cut out, and without Dr. Edmunds' reply, or your adjudication upon the controversy, has been sent by post to myself, to the Matron, and to the Secretary of this hospital (London Temperance Hospital), the directions being, as I believe, in the hand-writing of Mr. J. Mayall, jun.

It is obvious that this misleading reprint cannot have been sent to the Matron or Secretary of the hospital where Dr. Edmunds is senior physician except for malicious purposes; and as the reprint may have been widely circulated in other directions where Dr. Edmunds' reply, as published in your issue of the 10th inst. will never be seen, I think that an opportunity of repudiating all part in this contemptible act should be given Mr. John Mayall in your columns.

Yours, &c.,

SYDNEY L. SMITH, M.R.C.S., L.R.C.P.Ed.

London Temperance Hospital,
Dec. 13th.

[*** Having every desire to do justice to both sides, we have inserted the above short notes by way of explanation. Under no circumstances can we re-open the correspondence.—ED.]

LE DR. JOSE ROLRIGUES, Lisbon.—Many thanks.

DR. P. C.—Thanks for the information, which shall be utilised.

MR. B. and DR. D. are thanked; but the individual is beneath notice.

MR. FELLOWES will probably find what he requires at Stanford's, the Geographer, Charing Cross.

DR. BERKART.—Your communication, "On Benzoate of Soda in a Case of Syphilitic Lupus," shall appear, if possible, in our next.

APPOINTMENTS.

ADAM, J., M.D., Medical Superintendent of the Crichton Royal Institution, Dumfries.

BLAKELY, S., M.D., M.R.C.S.E., Certifying Factory Surgeon for the District of Fivemiletown, co. Tyrone.

HENRY, R., M.D., Certifying Factory Surgeon for the District of Brookborough, co. Fermanagh.

HOLMES, N. W., L.R.C.P., L.R.C.S.Ed., House Surgeon to the Manchester Southern Hospital for Diseases of Women and Children.

KNOX, T., L.K.Q.C.P.I. & L.M., L.R.C.S.I., Certifying Factory Surgeon for the District of Maguiresbridge, co. Fermanagh.

MCNEILL, J. P., M.D., L.R.C.S.I., Medical Officer for the Tiverton East and West Districts of the Tiverton Union.

MORRISSY, Dr. E., Medical Officer and Medical Officer of Health for the Kingscourt Dispensary District of the Bailliebrough Union, co. Cavan.

NAVY MEDICAL DEPARTMENT.—In accordance with the provisions of an Order in Council of Feb. 4, 1875, the under-mentioned Fleet Surgeons have been placed on the Retired List from the 30th ult., with permission to assume the rank and title of Retired Deputy Inspector-General of Hospitals and Fleets in Her Majesty's Fleet from the same date: A. Fisher, M.D.; H. Harkan; J. Long, M.D.

INDIAN MEDICAL SERVICE.—To be Surgeons-General: Deputy Surgeon-General R. Cockburn, of the Bengal Army; Deputy Surgeon-General W. Williamson, of the Madras Army. Deputy Surgeon-General E. C. Thorp, M.D., of the Bengal Army, retires.

Marriages.

MARKS—DODS.—On Sept. 23, at St. Mary's, Brisbane, Queensland, Australia, Charles F. Marks, M.D., eldest son of A. H. Marks, M.D., of Dublin, to Elizabeth, widow of the late B. S. Dods, of Dunedin, N.Z., and daughter of the late James Dickson Stodart, of Melbourne.

Deaths.

HUGHES.—On Nov. 22, at Lymestone, Devon, Robt. Hughes, F.R.C.S., formerly of Stafford, aged 77.

MORRIS.—On Dec. 13, at Combe Down, Bath, Trevor Morris, M.D., aged 84.

RABLAH.—On Dec. 9, at Hanover House, Scarborough, James Joseph Rablah, L.F.P.Glas., M.R.C.S.Eng., aged 37.

ROSSITER.—On Dec. 4, at Southfield Villa, Taunton, Frederick, Wm. Rossiter, Surgeon, aged 72.

TASKER.—On Dec. 8, at Melbourne, Derby, Richard Thomas Tasker, M.R.C.S., L.S.A.L., aged 61.

THOM.—On Nov. 11, at Lahore, India, Henry Thom, M.D., F.R.C.S., Surgeon-Major Bengal Medical Service, aged 48.

WELLS.—On Dec. 8, at Budleigh Salterton, Devon, Anna, widow of the late Wm. Wells, M.R.C.S.

IRISH POOR-LAW INTELLIGENCE.

CORRESPONDENCE.

POOR-LAW MEDICAL AMENDMENT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In my letter of the 22nd of October, adverting to the shortcomings of the Irish Poor Law Medical Service, I detailed and suggested remedial measures calculated to dissipate the more salient grievances under which we labour. Had that exposition been followed up, as expected, by several others, embodying the enlightened views and mature suggestions of our ablest members, the Irish Medical Association, encouraged by the support and assistance of the profession, would undoubtedly formulate and commend to general acceptance a feasible scheme of reform, worthy of the recognised ability and undeviating solicitude they have always evinced on our behalf. Though unsuccessful in the main, my letter has elicited some suggestive correspondence useful (apart from their intrinsic merit), by showing that there are still amongst us a few—active, generous, and ambitious—who grudge neither time, trouble, or money towards achieving the emancipation of their fellow chips. Much has, and more might have been accomplished, but that the bulk of the profession are immersed in hopeless, apathetic indolence, devoid of spirit, enterprise, and ambition. Alike callous and indifferent, they stand aloof from every effort of reform, withhold the petty contributions towards the Irish Medical Association, and even the medical journals, and yet (*O mores!*) they are not above grasping at the advantages accruing from the labours and resources of others as hard worked and ill paid as themselves.

Perusal of Swift's little fable, as given in page 472, *Medical Press*, 29th Nov., 1879, will be useful to all, inasmuch as the moral is simple and instructive, and should impress each of us with the necessity of co-operation and unity of action. As this can only be attained through the Irish Medical Association, our first effort should be to secure to that body a degree of support and recognition worthy of their deserts, and more creditable to the profession than any heretofore accorded them. The gentleman, who in your issue of the 5th of Nov., 1879, subscribed himself "One who receives little money and less thanks for his services," gave it as his opinion that if properly managed, almost every Poor-law medical officer in Ireland could be induced to contribute to the Association: I fully agree with him, and consider many suggestions contained in his letter worthy of note.

My original scheme commended itself, by reason of its fruition depending almost exclusively on ourselves. Dr. Haslet (*Medical Press*, Nov. 26, 1879) takes exception to making minimum salaries a condition of acceptance of office. I still hold this to be necessary, and feel that we are already in a manner pledged to it, for have we not, before getting our degrees, made a solemn declaration to sustain the honour and integrity of the profession by every means in our power? And I may add that, acceptance of those almost servile positions, at what I may designate menial remuneration, has by lessening professional pride and personal independence, done more to undermine the general character and social status of the profession than the united efforts of all our enemies could ever accomplish. Upon other remarks, anent my letter of the 22nd of October, I do not purpose making any comment, for, like my observations, they have not, I presume, escaped the vigilance of our Association, who will, no doubt, elide and attach due significance to every useful suggestion. If my talent and attainments were at all commensurate with the spirit and enterprise with which I have been gifted, there were amongst you a much needed "Brutus Anthony" who would stir up men's blood. But as things are, I only can and always will, exert myself to uphold the dignity, social status, and financial recognition of the profession to which I have the honour to belong. Though I purpose again returning to the subject of reform, I do not intend making any suggestions here; but it strikes me—and as time is of importance in the matter, it may be as well to mention—that the present would be an opportune occasion for the issue of a circular to every board of guardians in Ireland, conveying a petition to Government that forasmuch as Poor-law medical officers are as essential to the well-being of the State as their *confrères* of the army and navy, their entire salaries should, in like manner, be paid out of the Imperial exchequer, thereby relieving the over-burdened ratepayers of an unwarrantable imposition. Such a petition would, undoubtedly, be unanimously and ubiquitously adopted, and might be productive of much good. For some weeks past, through some postal or other irregularity deserving of attention, the *Medical Press* did not reach me, and I presume others, till Saturday afternoon, thereby precluding reply or comment in the next issue on any observations contained in the preceding number.

In deference to Dr. Haslet's suggestion, as appearing in the *Medical Press*, Nov. 26th, 1879, I append my name, though, as may be inferred, such was not my original intention.

Your faithful servant,

CHARLES E. CREAN, L.R.C.S.I., &c.

Ballyhannis, Dec. 6, 1879.

ABBEYLEIX UNION.

THE MEDICAL OFFICERS OF HEALTH AND SANITARY PROSECUTIONS.

THE following letters were read:—

"Durrow, November 17th, 1879.

"DEAR SIR,—Yours of the 10th inst. received, with a copy of a resolution passed by the Sanitary Authority on the 14th ult., viz.:—'That the salary to be paid each medical officer of health shall include his attendance at petty sessions in sanitary prosecutions.'

"With great respect I would observe that the terms of this resolution are not in accordance with the 258th sec. of the Public Health Act of 1878, which provides that any such arrangement shall be by agreement between the Sanitary Authority and the Medical Officer of Health, and I cannot consent to give my services at sanitary prosecutions

Digitized by Google

without remuneration. I beg respectfully to say that the resolution referred to cannot debar me from claiming the fees to which I am legally entitled under the above-mentioned section.

Yours, &c.,

"J. R. PALMER."

"Castletown, Mountrath, 11th November.

"DEAR SIR,—I received your circular, with a copy of a resolution adopted by the Board of Guardians at its last meeting. I will be obliged by your informing the Board that the resolution is in no way binding on me.

Yours truly,

"W. HANRAHAN."

STRADBALLY DISPENSARY.

THE Clerk read the following :—

"Stradbally, December 9th, 1879.

"SIR,—The medical officer of this district having notified to the honorary secretary his unfitness to attend to his dispensary duties owing to illness, there was an extraordinary meeting of the committee of management held this day to consider the appointment of a *locum tenens*. Dr. Percival having recommended Dr. Dugdale, the meeting unanimously agreed to it.

"JOHN M'LAUGHLIN, Hon. Secretary."

Mr. Brennan—I object, Mr. Chairman, to a meeting of that kind. I would not sanction any proceedings done at a meeting that was not convened by circular. There is a sentence in that letter to the effect that "the doctor recommended." The doctor should not have recommended anything; that is for the committee of management.

Chairman—In cases of this kind it is usual for the doctor to recommend a person as his *locum tenens*, and it is then for the committee to approve or disapprove.

The letter was then marked read.

[If Mr. Brennan will take the trouble to look at the 23rd of the Dispenaary Regulations, he will find that the medical officer is bound to "recommend."—ED.]

MONAGHAN FEVER HOSPITAL.

A MEETING of the subscribers to this institution and magistrates of the county was held, for the purpose of electing a physician to that institution in the room of Dr. Ross, resigned.

The Chairman said the first thing to be done was to ascertain who were entitled to vote. Those who had been subscribers for one year of a guinea and upwards, were entitled to that privilege. His lordship read the sections 4 and 5 William IV., ch. 26, bearing on the subject.

Mr. M'Minn said he would ask his lordship to read the other sections of the Act on behalf of Dr. Woods, especially 58 Geo. III., ch. 47, sec. 1.

After a long discussion, the Chairman believed the section he had read at the commencement prohibited every person from voting except those who had been for the year 1878 subscribers of one guinea each.

Applications were then read from Dr. Hall and Dr. Woods, together with their diplomas and testimonials. Applications were also read from Dr. Ingram and Dr. G. H. Young, of Old Town, Rathdowney ; but those gentlemen were not in attendance, nor had they sent forward testimonials.

The voting was as follows :—For Dr. Hall, 17 ; for Dr. Woods, 24.

Lord Dartrey declared Dr. Woods duly elected, by a majority of seven votes.

DROGHEDA UNION.

THE PUBLIC HEALTH ACT.

SIR,—I have the honour to report to you, for the information of the board of guardians of Drogheda union, that no case of infectious disease occurred among the dispensary patients in the St. Peter's (West) District, during the month of November.

I herewith enclose an extract from the annual returns of the district, contrasting the number of cases of preventible diseases which occurred in the district during the six years prior and the six years subsequent to the coming into operation of the Sanitary Act, which, I hope, may prove interesting to the guardians, and encouraging to the sanitary authority.

I have the honour to be, sir,

Your obedient servant,

J. BELLEW KELLY, F.R.C.S.I,
Medical Officer.

Infectious and Preventible Diseases which occurred during Twelve years ended 30th September, 1879.

For the six years prior to the Sanitary Act coming into operation.		For the six years subsequent to the Sanitary Act coming into operation.

WORKHOUSE COFFINS.

WE learn, from the *Ballina Herald*, "that at a recent funeral of a pauper in the parish churchyard, the rector and a number of people had to stand around the grave while a messenger was sent into town for a hammer and a few nails to put the coffin, provided by the liberality of the board of guardians, together, in order that it might be lowered into the grave with safety. It was a disgraceful spectacle, and the persons around were not sparing of their comments on the liberality of the Board."

THE WAY IRISH DISPENSARIES ARE LOOKED AFTER.

AT the last meeting of the Montmellick (Queen's co.) Guardians, the following letter was read :—

GENTLEMEN,—I beg to bring under your notice the state of matters here relative to medical appliances should any epidemic occur in this severe weather. There has been no committee formed since April, 1878, and, of course, no meeting held. In April, 1879, the late chairman and secretary attended, but no third party could be got to form a quorum, so matters remained as they were. I believe there has not been a medical inspector here for years, and if an examination of the drugs took place, it would be found that there is a great deficiency of those most useful and necessary things, and that a fresh supply is required. I am, &c.,

GEORGE NEALE.

The Chairman said the board of guardians could do nothing in the matter, if the committee did not think well of holding a meeting.

BALROTHERY UNION.

Dr. W. E. Adrien, of Oldtown has resigned as medical officer to the workhouse, a post he had held for nearly forty years.

The Board of Guardians, in accepting his resignation, adopted the following resolution :—

"That, in accepting the resignation of Dr. Adrien, we desire to place on record our deep sense and high appreciation of the very estimable manner in which he has at all times discharged the onerous and important duties of medical officer of our workhouse; and, while we regret that advancing years should render it necessary that he should sever his connection with us, we trust he may be spared to enjoy a long life of ease and happiness in his retirement from that position which he has so faithfully and efficiently filled for such a lengthened period."

OMAGH UNION.

DISPENSARY ASSISTANT.—MEDICAL OFFICER.

Another letter from the L. G. B. was read, as follows :—

"With reference to the minutes of the Board of Guardians of the Omagh Union, on the 1st ult., inquiring whether it was necessary for the Guardians to express their approval or disapproval of the proposal of the Committee of Management of the Omagh Dispensary District, to permit Dr. H. B. Fleming, medical officer of the district, to continue at his own expense the service of an assistant in the discharge of the duties of the district—the L. G. B. for Ireland desire to state that inasmuch as there is no salary in question, any expression of opinion by the guardians is unnecessary."

TO READERS.

The Editor will feel especially obliged by receiving copies of newspapers which contain any Poor-law or other intelligence of medical interest, in order that he may, if fit, republish it for the benefit of the readers of the *Medica Press.* Although twenty-one of the leading Irish newspapers are received at the Irish office, many things may escape notice which are deserving of attention. Newspapers should be marked, and addre sse to Dr. Jacob, at the Dublin office of this paper.

DIPHTHERIA.

By W. H. DAY, M.D.,
Physician to the Samaritan Hospital for Women and Children.

(*Continued from page* 517.)

Treatment.—This is a disease demanding local and constitutional measures, and from the first neither can be disregarded. Sometimes the local should be the most energetic, and sometimes the constitutional; but from the commencement the treatment must be supporting if not stimulating, and those measures that are most to be relied on in exhaustion and syncope are to be held in close reserve. Like other epidemics the disease does not admit of depletory measures, and all practitioners who have had a large experience of it, insist upon the necessity of employing a supporting plan of treatment. Each case will require some modification in accordance with its peculiarities and tendencies, so that it is not easy to lay down any exact rules to follow. The patient should be placed in a large and well ventilated room, the temperature of which should range from 60° to 65°. He should be kept absolutely quiet in bed with the head low, and all excitement carefully guarded against.

At the commencement of the disease a purge of calomel and rhubarb is sometimes required, so that some of the poison may be eliminated by the intestinal canal. This has been insisted upon by Sir William Jenner; and other observers have advocated this treatment at the beginning of the disorder, when the strength is equal to it. Under most circumstances, a mild saline aperient to keep the bowels regular, will be occasionally required, or a small dose of castor oil; still caution must be observed in the administration of aperients. Our best guide in this matter is the mildness or severity of the attack, for in the malignant form the child is overpowered by the poison at once and the pulse is so feeble that any depressing remedy would only hasten the tendency to fatal syncope. Milk in large quantities, beef tea, chicken broth, and eggs are the forms of nourishment best suited to maintain the flagging strength. Wine or brandy will be almost invariably needed, and the quantity must be regulated by the strength and frequency of the pulse. Where there is a tendency to syncope or failure of the heart's action, or the pulse is slow, very frequent, or irregular, considerable quantities of alcohol can be taken with advantage. Perseverance in the administration of food and medicine is imperatively demanded, and the attempt must not be abandoned under the impression that the child is unable to swallow, for this is constantly found to be erroneous.

When exhaustion is the leading feature of the case the child should not be allowed to sleep too long without nourishment. When the throat is painful, and there is thirst, a piece of ice to suck is very grateful and refreshing. A small quantity of iced water should be offered frequently if the mouth and lips get dry quickly. In the shape of medicine, the carbonate of ammonia, with the tincture of bark, is an excellent combination for supporting the system against exhaustion. When the skin is hot, and the temperature high, ice, cooling drinks, and diaphoretics (*a*) will be useful; with these may be combined the tincture of the perchloride of iron, (*b*) or the iron may be given alone, or with chlorate of potash. In most of the inflammatory throat affections of children this preparation of iron has a wonderful effect, and is as specific as in erysipelas, which may be

Digitized by Google

possibly due to some antiseptic properties which it exerts locally and possesses after its entrance into the blood. It requires to be given frequently, and according to some authorities in large doses. A small dose (m v. to m x.), with or without the dilute hydrochloric acid, once in four hours, is often enough in mild cases. If the tongue is furred, and the breath fœtid, chlorate of potash in combination with the acid is an excellent remedy, and recovery will take place under its steady continuance. Quinine, salicylic acid, benzoate of soda, when the temperature is high and the system depressed by the septic nature of the disease, are all useful. When the throat exhibits dark and softened portions of exudation, with a tendency to bleed when touched, or there is hæmorrhage from the mucous surfaces, then the perchloride of iron must be combined with it; and in this formidable complication a full dose should be given every hour or two, till the urgent symptoms are relieved. In most cases I prefer a mixture consisting of iron, chlorate of potash, and hydrochloric acid. (*a*) It is particularly suitable when the exudation is firm, the tongue coated, and the throat exhibits no hæmorrhagic tendency.

The chlorine drink recommended in scarlet fever is equally of service here. It is grateful to the little patients in relieving the throat and febrile symptoms when they are present. It possesses antiseptic properties, relieving pain and difficulty in swallowing, and improving the character of the exudation.

Quinine and the mineral acids are also useful variously combined. External applications to the throat, in the shape of leeches, blisters, and counter irritants, are in no case requisite, and will do harm. Warm poultices, fomentations, or water dressing, are comfortable and useful.

The applications to the throat internally are those indicated in scarlet fever, and the same precautions as to strength are to be observed. In young children who cannot gargle, a solution of borax may be applied to the throat (ʒss. to the ℥j.), or equal parts of the liquor ferri perchloridi and honey may be used with advantage. This is perhaps the best astringent application. In a case that came under my care a few years ago a thick solution of chlorate of potash, borax, glycerine and honey (*b*) gave much relief to the throat. At an early stage, when the membrane is thin on the fauces and tonsils, a solution of nitrate of silver (gr. x. or ℈j. to the ℥j.) applied with a camel's-hair brush twice in the twenty-four hours has been of benefit. The application of the solid nitrate of silver must be cautiously resorted to: indeed it is questionable whether this or any other caustic, as hydrochloric acid, or the acid nitrate of mercury, is ever necessary. They increase the pain and difficulty of swallowing, and at the same time aggravate the local mischief. If there is fœtor of the breath, and the parts incline to be sloughing and gangrenous, the solution of chlorinated soda, in the proportion of one drachm of the solution to two ounces of water, is an excellent application. This, and the iron solution, are two most valuable measures, according to my experience, in every stage of diphtheritic sore throat. Some children are so alarmed and frightened at the attempt to press down the tongue, and apply remedies to the throat, that these measures had better be given up altogether in such cases. Nervous and delicate children are almost thrown into convulsions by their struggles and resistance, and where these remedies cannot be used there is consolation in remembering that escharotics are of doubtful efficacy, and even according to some English and foreign physicians, who have had great experience of the malady, decidedly injurious. In diphtheritic affections of the throat the carbolic acid spray will often be found very useful, just as it is in the faucial affections of scarlet fever and measles. Lime water, lactic acid, &c., have been also used in like manner with success.

When the disease has extended to the larynx and trachea, and symptoms of croup have arisen, an emetic of ipecacuanha, or sulphate of zinc, is advisable if the strength is equal to it; and, after its operation, stimulants and nourishment should be freely administered.

As regards the operation of tracheotomy when death threatens from suffocation, and dyspnœa is urgent, Dr. Buchanan, of Glasgow, has recorded some interesting cases of success. Out of thirty cases he had eleven recoveries. (*a*) Two highly interesting cases of successful tracheotomy in the last stage of diphtheria have been recently brought before the Clinical Society, by Mr. George Lawson and Mr. Pugin Thornton (Feb. 28, 1879).

But supposing the non-identity of croup and diphtheria is admitted, and that the diseases are in many respects clinically and practically different, still both are prone to terminate fatally by exhaustion, or by suffocation, and these urgent symptoms would seem, at least, to demand the same line of treatment. When the latter condition threatens, and all other remedies have proved useless, we allow that tracheotomy is justifiable in the former disease, and that the operation has rescued many a little sufferer from an agonising death. (*b*) Henceforth we must look upon tracheotomy in diphtheria as a proper step to take when the child is beginning to struggle for its breath, and the strength is departing; when the features are livid from obstruction to the circulation, and the mischief is limited to the trachea and larynx. If the larger bronchial tubes are involved there will be no objection to the operation; but if viscid secretion is blocking up the smaller tubes, and there is any sign of pneumonic consolidation, then the operation had better not be attempted.

For the anæmia and nervous affections which follow diphtheria, citrate of iron and quinine, the mineral acids and calumba should be employed. Strychnia is also very useful. For any albuminuria and prolonged weakness, the tincture of the perchloride of iron and hydrochloric acid are the best remedies.

The throat to be mopped out with a little of this solution frequently during the day.

(*a*) There is a case of diphtheria recorded in the *Lancet* (Nov. 29th, 1873, p. 771) that fell under the care of Dr. Murchison, at St. Thomas's Hospital, in which the dyspnœa was so urgent, that tracheotomy was performed. A little thick exudation was removed, with immediate relief to the breathing. Death occurred in twenty-five hours afterwards. With the return of embarrassed breathing the temperature rose to 107°·6, and at the time of death fell to 104°·5. The interior of the larynx and trachea was completely lined by a layer of false membrane, which was firm in some places, and easily detached in others. At about the fourth ring of the trachea it could be separated in a complete layer, beneath which the surface was red and raw-looking, and "studded with minute vascular points." The larger bronchi, as far as the third or fourth division, were filled with a curdy fluid, and some of the smaller bronchi were dilated. The state of the small intestines was the chief point of interest in the case, as the child was said to have been quite well the day previous to admission. The solitary and follicular glands of the small intestines were distinct and prominent throughout, and there were three or four small rounded ulcers apparently connected with them at the middle third of the ileum. In the ileum also there were three or four ulcers of irregular shape with raised edges, and the Peyer's patches had undergone a change resembling that met with in the earlier stages of typhoid fever. The large intestines were healthy. Both lungs were collapsed and dense; the right cavities of the heart were distended with dark, perfectly coagulated blood. It would appear that although tracheotomy temporarily relieved the distressing dyspnœa, no hope of recovery could have been entertained, where the local mischief was so extensive, and the effect of blood poisoning had become so general.

Clinical Records.

LOUTH COUNTY INFIRMARY.

Hæmatocele from Rupture of Hernial Sac.—Strangulation.—Death.

Under the care of HERCULES MACDONNELL, M.D., M.Ch. Univ. Dub.

P. McP., æt. 45, was admitted into hospital on August 22nd; five years ago he noticed a swelling in his left inguinal region, which was recognised as a hernia, and for which a truss was regularly worn. On the evening of the 20th, when jumping down off a cart, he felt a snap in his scrotum, which gradually swelled up, and he experienced intense pain. The following day he was seen by the medical officer of his district, when an unsuccessful attempt was made to reduce the hernia. The following morning he was admitted into hospital. His face wore an anxious expression; on examining the scrotum, a tense, bluish, semi-fluctuating mass was seen, measuring in the lateral circumference 25 inches, and from the perineum to the root of the penis, 22 inches. The penis was intensely œdematous, measuring 5 inches in circumference. The bowels had not been moved for 3 days; there was no retention of urine. In addition to the general enlargement, a distinct tumour could be felt, occupying the left inguinal region.

A large soap and water enema was thrown up, and a hot bath given; an incision was made into the scrotum in front, and 21 ounces of dark fluid evacuated. This gave instant relief. Dressings, spread on tenax, were applied; one-grain doses of opium every sixth hour were ordered, and iced milk and lime water in small quantities allowed. At 8 p.m., temperature was 99·8°, pulse 90; bowels not moved; no retention of urine.

August 23rd.—No sleep last night: some greenish matter was vomited; no motion from the bowels; temperature 99·°, and œdema of penis gone. The redness has left the right side of scrotum, but the left is still much enlarged and tense: some black discharge has come away on the dressings. Hernial neck now well defined, slight gurgling heard on manipulation.

4 p.m.—Given a long bath at 100° F., half a grain of morphia subcutaneously injected, and the operation for the division of the hernial structure was commenced, spray being used. No difficulty was experienced in reaching the sac, which was very much thickened; on opening this, the intestine was perceived to be extremely congested. The stricture was divided freely, but considerable, and at the time unaccountable, difficulty was found in returning the intestine, of which there were three large loops down. Antiseptic dressings were applied, and the patient removed to a well-warmed bed.

At 11 p.m., the patient complained of feeling sick, and some flatus escaped, but during the act of vomiting he fell back dead. He was quite cheerful a few minutes before, and felt no pain.

Autopsy, twelve hours after Death.—Rigor mortis well marked; penis and scrotum discoloured, also left inguinal region. On removing the silver sutures, and prolonging the incision downwards, laying open the scrotum from apex to base, about one drachm of dark-coloured fluid escaped. The sac of the hernia was adherent for a great part of its extent, the testicle smaller and softer than normal. At the lower and back part of the sac where it began to turn forward, was a rent about one inch long, it was of a lacerated description. This was evidently the cause of the hæmatocele, and also the great difficulty in returning the intestine after the hernial stricture had been divided, a loop of the intestine being incarcerated in the rent in the sac. The intestine was completely pervious, and though congested, in a fairly healthy condition. I could find no cause to account for the sudden death in the abdominal cavity, and did not make any further examination than that already detailed.

The presence of an hæmatocele with strangulated hernia is sufficiently rare to merit notice, but I am not aware of any case where the post-mortem revealed the cause of the hæmatocele to have been rupture of the sac.

Special.

FRANCE.

(FROM OUR OWN CORRESPONDENT.)

PARIS, 8th DECEMBER.—At the meeting of the Académie de Médécine, held last week, Dr. Vidal read a paper on the treatment of lupus by linear incisions. Having operated on 120 patients since 1875, M. Vidal has been able to study the effects of scarifications in every variety of lupus and in all its stages. In exposing his researches he mentioned the names of several medical men who adopted this new mode of treatment in a more or less modified form, among whom was Dr. Balmano Squire, of London, who after making the incisions used a solution of chloride of zinc as a caustic. M. Vidal gives the preference to simple parallel incisions, and made as near to each other as possible. The loss of blood is trifling. After five or six scarifications, which can be made at an interval of six or eight days, there is an appearance of a cure. But through the cicatrix may be seen certain white points which are minute tubercles, which must be destroyed by passing the needle through the cicatrix. This is the most tedious part of the treatment, and must be continued until all vestiges of the disease have disappeared. M. Vidal terminated by the following conclusions:—1st. The treatment of lupus by scarification is a less painful and the surest mode to prevent a return of the disease. 2nd. It is applicable to every form of lupus, ulcerating or non-ulcerating.

At the Surgical Society a discussion has been going on for some time between M. Verneuil, M. Tillany, and others, relative to the treatment of acute or chronic arthritis as regards the degree of motion, if any, to be allowed to the limb. M. Verneuil contended that the articulation should be left in an immovable position during the whole period of treatment, while M. Tillany, who recognised the necessity of keeping the limb in a fixed position during the inflammatory stage, yet as soon as inflammation had subsided he would give every freedom to the articulation. On the other hand, M. Championière declared that he had practised several operations on the articulations, and never saw the necessity of depriving them of all motion.

In France it is the custom amongst the confectioners to use chromate of lead to colour their cakes. This pernicious practice has originated in Paris, where the eggs are so dear.

A young English lady, Miss Blanche Edwards, has just passed successfully her first examination at the Faculty of Paris.

THE STUDY OF OPHTHALMOLOGY IN MEDICAL SCHOOLS.

PROBABLY few of our readers are aware of the efforts which are being made to obtain for ophthalmic surgery a place as a compulsory subject in the curriculum of medical study. The medical world is just now convulsed with the discussion of medical reform, and this is therefore the time for ventilating so very important a question. In March last an influential meeting of ophthalmic surgeons was held in London for the purpose of taking steps in this direction, and the following petition to the General Medical Council was adopted:—

"*The Memorial of the undersigned Ophthalmic Surgeons*

"HUMBLY SHEWETH—That the study of ophthalmic surgery

Digitized by Google

and medicine is at present greatly neglected in the ordinary course of medical education, candidates frequently obtaining their diploma with little or no knowledge of diseases of the eye. The consequences of this, both to the public and to the practitioners themselves, are very serious, as your petitioners, have ample opportunities of observing. That in Continental examinations, as well as in those conducted in the Indian University, a sound knowledge of ophthalmology is required. That your petitioners believe that the advances made in ophthalmic surgery within the last twenty-five years render it advisable that it should be taught as a separate subject. That the arrangements for its study already exist in most of the hospitals of Great Britain and Ireland, but are not taken advantage of by students because little or no evidence of acquaintance with the subject is required by the licensing bodies.

"Your petitioners desire to draw the attention of the Medical Council to the advisability of making it compulsory upon all medical students to attend a three months' course of practical ophthalmology, either at the special eye department of a general hospital, or at a special ophthalmic hospital, as well as a course of twenty lectures on ophthalmology at the least. They also desire to press upon the Medical Council the importance of making ophthalmology form a distinct subject of examination at the pass examination for surgical diploma, or at the examination of a conjoint board."

Copies of this petition were forwarded by the Council to the various licensing bodies for their observations and report thereon, and now all, or nearly all, the answers from those bodies have been sent in. Before briefly referring to these replies, we would wish to point out the grounds upon which, as it seems to us, the prayer of the memorial is a most proper one, and we believe the following propositions will be admitted on all hands :—

That it is the duty of every licensing body to see that its graduates do not habitually go into the world absolutely ignorant of any given organ of the body and its diseases. That the vast majority of students do at present become surgeons without any knowledge of the eye and its diseases. That the reason of this is because through the force of circumstances ophthalmic surgery has, within the last twenty-five years, become completely separated from general surgery as regards its teachers, its hospital practice, and in private practice, as did midwifery at an earlier date; and that consequently students do not now imbibe a knowledge of the diseases of this organ along with that of others in the ordinary course of their medical studies. That diseases of the eye are amongst the most frequent with which medical men in general practice have to deal, and, consequently, that some knowledge of them is most valuable to the practitioner. That even minor maladies of the eye, which only temporarily or partially affect the sight, are as serious for the well-being of the patient as those of any other organ of the body, and should command as much attention from the student.

In nearly every one of the answers sent to the memorial we find one very natural objection to its prayer put forward—namely, that the curriculum is already overcrowded, and that it would be unfair—indeed, impossible—to require the student to attend any more lectures. These same replies are otherwise favourable to the proposal, and express a hope that in any change in the curriculum ophthalmic surgery may obtain a place. Some of the licensing bodies present a decidedly hostile front to the memorialists. These are the Royal College of Surgeons of Edinburgh, which sends a verbose and laboured reply, the University of Edinburgh, the College of Physicians of Edinburgh, the College of Surgeons of England, and the University of London, the latter two assigning no reason. A chief argument against the proposal put forward by the three Edinburgh bodies is that ophthalmology is a specialty, and that, if it be admitted as a separate compulsory subject in the curriculum, other "specialties," such as cutaneous disease, urinary disease, diseases of the rectum and anus, &c., must also be admitted to a similar position. Can anything be more absurd than this? In the first place, although some medical men do obtain special reputation for the treatment of such affections, yet in hospital practice the latter are not, and need not, be made separate branches of surgery, but do truly form an integral part of it, and are learned as such by medical students; and, in the next place, to compare the extent or difficulty of the study of such specialties with that of diseases of the eye is only to display the ignorance of ophthalmology possessed by the individual or licensing body which makes the comparison. If it were found that for any reason students obtained their diplomas, as a rule, wholly ignorant of diseases of the rectum and anus, or of urinary disease, it would become necessary to take suitable measures to correct that defect in their education. We do not ask that students should be required to know more about the eye than about any other organ of the body; we merely ask that they should know as much about it as about any other organ of the body. Is it desirable that the general practitioner should be able to treat the minor maladies of the eye and diagnose the more serious ones? If so, the memorial of the ophthalmic surgeons is a most proper one, because there is no other mode than that which it suggests for remedying the defect it points out. We have great pleasure in appending in full the answer to the memorial sent in by the Royal College of Surgeons in Ireland, which reflects honour and credit upon its Council :—

"Nov. 21st, 1879.

"My Dear Sir,—I beg leave to forward you a copy of the following resolution adopted by the Council of this College at their meeting held yesterday :—

"'That the Council of the College of Surgeons in Ireland concur in the views expressed in the memorial of the ophthalmic surgeons, as regards the defect in the professional education in the matter of ophthalmic surgery, and the great importance of remedying that defect.

"'The Council considers the course of study in the diseases of the eye, as suggested in the memorial, a fair and reasonable one.

"'The Council would gladly require such a course of study for their diploma if the other licensing bodies would join in demanding it. The only objection which the Council see to its introduction is the already overcrowded condition of the curriculum.

"'The Council would therefore hope that in any rearrangements of the curriculum of the licensing bodies at large, or in case of the adoption of conjoint schemes, the suggestions put forward in the memorial may be favourably considered.'

"I remain, faithfully yours,

"J. Stannus Hughes, Sec. of Council."

Dr. Headlam Greenhow has resigned the post of Physician to the Middlesex Hospital, which he has held for many years.

In the new Buffalo Homœopathic College it is announced officially that "during the lectures, and amphitheatre cliniques also, the female students are screened from the gentlemen, while they have the same advantages."

The effect of the continued severe weather is shown most unmistakably in the Registrar-General's last weekly returns of the rates of mortality in the large towns of the United Kingdom, they were—Sunderland 18 per 1,000, Portsmouth 20, Brighton 21, Oldham 22, Sheffield 23, Norwich 24, Edinburgh 25, Newcastle-upon-Tyne 26, Hull 27, Bristol 28, Bradford 29, Leicester 29, Manchester 30, Nottingham 30, Glasgow 31, London 31, Leeds 32, Wolverhampton 33, Birmingham 33, Plymouth 35, Salford 37, Liverpool 41, and in Dublin the highest rate of all 44 per 1,000.

POOR-LAW MEDICAL OFFICERS' SUPERANNUATION FUND.—III.

It would be of supreme importance, for the success of such an undertaking as we are now engaged in examining that there should be a good reserve fund wherewith to meet any casual and extraordinary increase in the demands upon its resources. Although we cannot say there would be any large reserve under this scheme, yet we may point out that for many years the income of the fund would be largely in excess of the expenditure. Supposing that every medical officer in Ireland became a member of the fund, which we admit would be an impossibility only put forward as an illustration, the balance-sheet of the first eight years' operations would be as follows:—

INCOME.		EXPENDITURE.	
First year.		*First year.*	
By subscription of 1019 members at 14s. 1d.	£2860	To annuities to eight widows	£160
Deduct expenditure . .	610	Allowance to 20 orphans	200
		Working expenses	250
Balance in hand, .	£2250		£610
Second year.		*Second year.*	
By balance in hand ...	£2250	By annuities to 16 widows	£320
By subscriptions	2860	Allowance to 40 orphans	400
By interest on £2250 at 5 per cent.	112	Working expenses	250
Total income... ...	£5222		
Deduct expenditure	970		
Balance in hand ...	£4250		£970
Third year.		*Third year.*	
By balance in hand ...	£4252	Annuities to 24 widows	£480
By subscriptions	2860	Allowance to 60 orphans	600
By interest on £4252 ...	213	Working expenses ...	250
Total income	£7325		
Deduct expenses ...	1330		
Balance in hand ...	£5995		£1330
Fourth year.		*Fourth year.*	
By balance in hand ...	£5995	Annuities to 32 widows	£640
By subscription	2860	Allowances to orphans	800
By interest on £4995 ...	300	Working expenses ...	250
Total income... ...	9155		
Deduct expenses ...	1690		
Balance in hand ...	£7465		£1690
Fifth year.		*Fifth year.*	
By balance in hand ...	£7465	Annuities to 40 widows	£800
By subscriptions ...	2860	Allowances to 100 orphans	1000
By interest on £7465...	373	Working expenses ...	250
Total income ...	£10,698		
Deduct expenditure	2050		
Balance in hand...	£8648		£2050
Sixth year.		*Sixth year.*	
By balance in hand ...	£8648	Annuities to 48 widows	£960
By subscriptions ...	2860	Allowances to 120 children	1200
By interest on £8648	431	Working expenses ...	250
Total income ...	£11,939		
Deduct expenses	2410		
Balance in hand...	£9529		£2410
Seventh year.		*Seventh year.*	
By balance in hand ...	£9529	Annuities to 56 widows	£1120
By subscriptions ...	2860	Allowances to 141 children	1410
By interest on £9529	476	Working expenses ...	250
Total income ...	£12,865		
Deduct expenses...	2780		
Balance in hand...	£10,080		£2780
Eighth year.		*Eighth year.*	
By balance in hand ...	£10,085	Annuities to 60 widows	£1200
By subscriptions ...	2860	Allowances to 141 children	1410
By interest on £10,085	504	Working expenses ...	250
Total income ...	£13,449		
Deduct expenses	2860		
	£10,589		£2860

From this table it will be observed that, inasmuch as the demand upon the fund would accrue *gradatim* while the income would be steady from the beginning, the first eight years' operations of the fund ought to produce a considerable reserve. Of course, the smaller the number of contributors, the slower the reserve fund would grow, but the result would be the same in the end, and eventually the fund would have an income of interest on its reserve of £500 a year wherewith to meet contingencies, and put by something from year to year.

We have next to consider some of the difficulties, and there are several considerations which suggest themselves, in arranging the details of such a system, to which we must call attention,

Digitized by Google

The first that presents itself is the difficulty which would certainly arise in inducing Poor-law medical officers to become subscribers when they have no idea of marriage. Of course, if the joining of the fund were made an essential condition of appointment, this difficulty would be overcome, and every member of the service would be benefited by it. We should be content to start with men under forty-five or fifty as a nucleus, adding to it from year to year the young men, according as they took office, until after about fifteen years we should have the entire number upon the books of the fund.

The second difficulty is that some guarantee would be necessary that the member entering is in fair health. The member whose health is worst is he whose wife and children most need protection, and to fulfil its objects perfectly the fund ought to exclude no Poor-law medical officer. This is an axiom of importance, and theoretically true. If we could ensure, by compulsory enactments or otherwise, that members should join the fund when they receive their appointments, this difficulty would be in a great measure obviated, and the risk of unhealthy lives would be covered by the preponderating influence of healthy lives.

The third difficulty arises in connection with the position of a member who falls into ill-health, is no longer able to hold his appointment, and fails to obtain superannuation, so that he has neither a salary from which to make deductions, nor an income to enable him to pay the required sum.

Under such circumstances, the only course which appears possible would be to dispense with further payments, the fund being liable only for reduced annuities proportionate to the amount previously paid into it.

In conclusion, we must observe that we fully believe that the Poor-law medical officer is entitled to superannuation, but the organisation we are analysing does not in any way prevent the Poor-law medical officers from insisting on their just claim for this measure; nay, more, we even hope that when Government sees how willing and how anxious medical officers are to make provision for their wives and children all true statesmen in the Cabinet will be disposed to lend them a helping hand, knowing that the thrift and savings of the Poor-law medical officer must result in increased benefit to the whole country, and that Government itself would obtain a certain return or percentage from the accumulated savings of the Poor-law medical officers, so that any outlay on superannuation would be amply compensated for, if not covered by the advantages derived from having a Poor-law constituency above the reach of want. We need hardly say that the intention of such a fund is not in any way to supersede the necessity for life insurance or to interfere in any way with other provisions.

It will only, at the best, serve as a guarantee to the Poor-law medical officer, who is unable to make adequate provision, that his widow and orphans will not, in the event of his premature death, be actually dependent on charity.

We have observed, with regret, that in some of the petitions, in reference to the Poor-law medical service, a degrading tone has been taken, and the maintenance of the wives and children has been introduced to the "charitable consideration" of her Majesty, with a plea "that Poor-law medical officers are wholly unable to lay by anything for their families." We are painfully aware that the Poor-law medical officer is, unhappily, placed under such circumstances that he is unable to make a handsome provision for those depending on him, because his salary is small and his professional expenses are large, yet we are of opinion that by the exercise of a little self-denial and prudence and by the power of co-operation, he would be able to make a provision which would place those dependent on him above eleemosynary aid.

We object, in the name of the profession, to petitions framed in a strain of pitiful supplication, and we would prevent a repetition of such degradation. If the Poor-law medical officers of England are able to make provision for their wives and children this scheme will be unnecessary, if not, our data must be of invaluable service to them.

THE ARMY MEDICAL WARRANT.

The long-expected and important Charter of the Military Medical Service was issued so close upon our day of publication that a verdict upon its provisions at the moment must necessarily have been hasty and half-considered, and might have proved a mistaken judgment, and we therefore deferred expressing any opinion as to the merits or demerits of the new regulations until we had a fair opportunity of weighing them.

At once we feel justified in pronouncing the Warrant, as a whole, to be a good and fairly liberal measure, and we anticipate that it will be accepted by the profession as satisfactory, if not perfect. The scale of daily pay of the medical man is amended by it to a tangible extent, and it must be allowed that in this respect Her Majesty's Service is a fairly remunerated employment. Moreover, the power to a medical officer to retire into the Reserve at £1 a day, after twenty years' service and at the age of fifty-five, is a very substantial gain to him, and is worth a good deal in money's worth.

But the question between the War Office and the surgeons has never been a question of money, for although the pay has not been hitherto very liberal it has always been sufficient to attract candidates, if no other reason existed for their keeping aloof from the service. It is in the improvement which the Warrant effects in the social condition of the surgeon that its claim consists. In the first place a new rank of Brigade Surgeon has been created—the first time that a rank equivalent to the military brevet has been thrown open to the surgeon irrespective of his seniority. Henceforth there will be in the service something to work for and some honour to deserve, and we have at length bid adieu to the old system which rewarded officers simply because they grew old. Then, again, the restoration of horse allowance to the surgeon—though in itself a small matter—removes one of the most irritating and unjust distinctions maintained under the old system between the combatant officer and the doctor.

The restoration of the principle of exchange is at once a graceful concession and an act of obvious justice, and the abuse of the privilege is guarded against by the new rule, which requires every medical officer to have ten years'

Digitized by Google

foreign service to qualify him for promotion to the administrative rank. Thus, those surgeons who exchange and remain at home when there is foreign service to be performed will sacrifice their ultimate prospects; while, on the other hand, those occasional instances in which surgeons have been compelled to go abroad, leaving their wives in extreme sickness, need never occur again. We must hope, however, that this boon will not be neutralised by any *arrière pensée* of rules hereafter to be devised. Finally, the extension of sick leave to twelve months is a very reasonable concession, and one which removes an excuse for much bickering and ill-feeling which has hitherto existed in the service on this score.

As against these improvements in the regulations, we think it right to put a matter to which a correspondent of the *Lancet* calls attention:—

"Clause No. 22 of the new Warrant runs thus:—A medical officer, after completing ten years' service, may be *permitted* to retire on the gratuity or pension laid down in Article 47, *when it shall be deemed expedient* by our Secretary of State, &c.

"By the old Warrant, a medical officer, after twenty years' service and upwards, desiring to leave the army, need only apply to retire; his resignation must be accepted without favour or affection, and he was perfectly free to make any plans for his future life he might think fit, without any fear of interference. If invalided, he received 16s. 6d. after twenty years' service, and 20s. on the completion of twenty-five years' service; he was able almost invariably to procure a Medical Board, so that practically he could command 20s. a-day after twenty-five years' service.

"But how stands the matter now? Unlimited power is placed in the hands of the Director-General! for, of course, the Commander-in-Chief would sanction, and the Secretary of State approve, whatever the Director-General recommended. A medical officer in favour would naturally find no difficulty placed in his way of retirement; but, should he be without interest or have given offence to the authorities, a dearth of medical officers, or any excuse the Director-General of the time might choose to give, would suffice to prevent his resignation being accepted, however urgent his reasons for retirement might be; if in ill-health he can only obtain temporary half-pay, and if of a sound constitution he must go wherever he may be ordered, no matter at what sacrifice, or absent himself, and so render himself liable to the penalty of having his name removed from the Army List, and his pay and right to pension forfeited."

There are two other points in the Warrant of great interest and worthy of comment. Regimentalism—which everybody saw was moribund—has parted with its last breath, and gone to the limbo to which the purchase system and the ten years' service system have been relegated. On the whole, we do not regret the fact, and though the dis-regimentalising the doctor was a painful process, we are satisfied that the operation is over and the profession none the worse for the ordeal. Henceforth the army doctor will lack the inestimable feast of reason and flow of soul, which we all know, is the attribute of the mess-room, and of association with the average combatant officer. A few of the juveniles of the army medical service will no doubt fret, because they are, in their own idea, less fashionable and more professional than they were; but we quite expect that when their worship of Dundrearyism cools down, they will feel that, on the whole, it is better to be the co-equal of educated gentlemen than the tolerated associate of a *jeunessee doré*. In any case the change was inevitable, and the necessity ought to be accepted without grumbling.

We have had pleasure in speaking of the Warrant in a vein of unwonted approval. We are obliged to make one important exception, and to condemn the proposed system of appointment of surgeons upon the nomination of medical schools as unexceptionably foolish and hopelessly objectionable. As to the method of working out this proposal, we confess ourselves as totally wanting in comprehension, but the faults of such a system are on the surface and are not affected by detail. Supposing it practicable that one-half the army surgeons are to be chosen upon the recommendation of medical schools, and the other half by competitive examination, the result would, to our mind, be calamitous. It would at once create two classes of medical officers—the competition "wallah," sneered at by the nominated surgeon as a "cad" whose position was made by book-learning, and the nominated surgeon, sneered at by his competitive *confrère* as a dolt, who was pitchforked into a position to which he could not win his way by brain or industry. We should have, as a chronic condition of the Queen's service, the same feeling towards the nominee as that which exists in civil practice towards a man who buys his Fellowship or receives it in a year of grace. Such a system would be the parent of every evil and every disturbing element in the department. But supposing such an arrangement desirable, we insist that it is wholly impracticable, for at once we say that medical schools are totally unfitted to make the selection which is to be entrusted to them. Before three years had elapsed, we believe the school nominations would have been resolved into a simple system of purchase and of favouritism, with all the concomitant nepotism and ill-blood which circumstances must inevitably produce. We confidently trust that the better sense of the War Office authorities will convince them that their wisest course is to strike their pen through the ridiculous suggestion.

In conclusion, we must not allow our readers to forget that there is a danger that what was done before may be done again, and that great vigilance must therefore be exercised, lest the benefits to which we have referred should be clandestinely curtailed by subsequent Army Circulars. To be fore-warned is to be fore-armed, and we believe we may trust our brethren within the department to give us—and those who, with us, are anxious to assert their rights—timely notice of any such move, however innocent it may seem to be.

With the exercise of such care, with an honest disposition on the part of the War Office and Horse Guards to give effect to the Warrant, and with a fair spirit of give-and-take on the part of the army medical officers, we are confident that the year 1879 will open up a new era of prosperity and popularity for Her Majesty's Army Medical Department.

METHOD OF MEDICAL EDUCATION.—III.

EDUCATION GRADATIM.

WHILE insisting upon the insufficiency of an examination, *per se*, however well designed and conscientiously carried out, as a sole criterion of capacity for medical practice, we readily admit that it is the evidence upon which most dependence can be placed—it is, in fact, the only test which the licensing body has within its own control, which is entirely independent of both student and teacher, and which might, if extended and perfected, be made searching and very efficient as a proof of the student's knowledge. From circumstances to which we refer hereafter, it cannot be wholly reliable, and even if vested interests could be disregarded, it would still be necessary to adhere to curriculum in order that we may have some evidence that the student has actually seen and appreciated that upon which he answers at his examination.

The professional education of the student may be divided into—(*a*) Preparatory; (*b*) Primary; and (*c*) Practical.

It is indeed one of the most serious faults of existing systems that they take but little cognisance of this very natural gradation of study, and mix up clinical work, anatomical study, and preliminary scientific learning to the helpless confusion of the youthful student.

And here we must pause to urge upon our readers that the existing system of education is greatly defective, in that it does not fully recognise the prudence of proceeding step by step from the elementary, through the full medico-chirurgical arena, on finally to the practical application of those studies. It is not many years since such gradation was wholly ignored, and the student being examined but once, at the termination of his career, was encouraged to combine the whole of his subjects of study in one unsystematic heap, and bring with him into the examination hall as much of the confused mass of knowledge as his brain would hold for the purpose of one great effort, which constituted the beginning, middle, and end of all his learning. Even now the student is permitted by some licensing bodies, under certain circumstances, to do this; and the system usually in operation—while it recognises the necessity for gradation to a certain extent—does not go, we think, as far in that direction as it should. The first examination for instance of the Royal College of Surgeons in Ireland is the acme of *three* sessions of study. It involves the production of three sessions' certificates in anatomy, physiology and dissection, two in chemistry, theoretical and practical, and one each in materia medica, botany, and forensic medicine. It comprises, indeed, the whole domain of medical education, saving its practical application to medicine and surgery, and comprehends everything that the student is expected to know, excepting the actual practice of his profession. Our suggestion is that this examination is too comprehensive—that it is placed too far forward in the education of the student—that it involves a mass of knowledge which it is very difficult for the examiners to test within the limits of one examination of reasonable length, and that it affords an inducement to students to postpone the whole of their theoretical work and the foundation of their profession until the last six months of their third year of study. Moreover, the extent of the subjects upon which the student has to be tested makes the preparation for examination an exhausting effort on the part of the student, and makes the examination itself a prolonged and severe test.

We think that this examination should be subdivided and relieved by an examination in preparatory subjects, to be held at the end of the first year, that that first examination should include chemistry and physics, botany, physiology, and structural anatomy; and that regional and practical anatomy, histology, materia medica, and forensic medicine should be reserved for the second and third examination.

We submit that the establishment of a preparatory examination at an earlier date than the end of the third session would be not only no additional incubus upon the student, but would be a sensible and grateful relief to him. It would enable and encourage him to rid his mind of the preparatory subjects which, under the present system, he is obliged to keep in study until the end of his career is approaching. It would ensure his applying himself to these subjects during the first months of his studentship, and would prevent the too prevalent habit of idling.

The "preparatory" education, as we have said, we take to mean the elementary education special to the study of medicine, apart from the "preliminary" general education of which I have spoken. It is sufficiently obvious that some such education is needful; yet, under our present system, its necessity is wholly ignored.

A school-boy of sixteen is plunged at once *in medias res*. He is "entered" for and required to attend lectures on muscular and osseous machinery without having the remotest notion of mechanical principles. He is told about the growth of structures without having heard previously a syllable of elementary physiology. He is taught of the chemical constituents of these structures without having ever previously heard even the names of those constituents. There is, in fact, in our schools usually no teaching suitable for the first year's student, nor is his time appropriated on any intelligible principle. He is "entered" for whatever courses he or his mentor pleases, and is a partaker in the instruction given for the benefit of advanced students, by which means he, in process of time, picks up a little which he understands from a vast quantity of matter which is utterly incomprehensible to him.

This arises from the fact that the lecturer has but one standard of lecture, and is unwilling to burthen himself with a subdivision of his subjects. He constructs a course of lectures as suitable as he can make them to the wants of the advanced student and the requirements of the examination for which that student is studying, and this course he repeats *in sæcula sæculorum*. Usually the information conveyed in it is insufficiently developed for the wants of the student who is finishing his education; always it is incomprehensible to the student who is just beginning, and we are convinced that much of the unpopularity into which lecture-teaching has fallen has arisen from the fact that lectures are made to suit but one

Digitized by Google

class of students, and are regarded by the others as an incubus.

The "preparatory" education of a student should, in our opinion, consist in—

(*a*) Elementary Chemistry.
(*b*) Elementary Physiology.
(*c*) Elementary Anatomy.
(*d*) Physics—heat, light, electricity.
(*e*) Elementary Mechanics.
(*f*) Elementary Botany.

We think it hardly necessary to argue as to the necessity for the knowledge of these subjects as preparatory to the study of medicine or surgery. It will, we are sure, be felt by all our readers how unreasoning and unreasonable it is to require a school-boy to attend and listen to lectures on animal functions and physiology, he being wholly ignorant either of the nature of the material upon which he is lectured, or of the physical conditions which influence it. Can it be defended that a student should be taught of the ingestion of oxygen by the lungs and of aliments by the stomach, and of the elimination of carbonic acid, urea, and bile, he having hardly even heard of these substances?

Is it tolerable that he should be told of the nerves of special sense, the transmission of stimuli to the cones of the retina, or the nerve of the ear, without having previously received the least teaching upon the nature of and laws which govern light and sound?

Is it not paradoxical to speak to him of the "rhizome" of podophyllum, and the "corm" of colchicum, when he may be in perfect ignorance of the elements of botany; to require him to comprehend the use of the clinical thermometer; the testing of urine chemically and microscopically before he has learned the use of a test-tube or a microscope; to preach to him as to the causes of displacement in a dislocation before he knows the elementary laws of mechanics?

To do so does not admit of defence, and yet all students are treated in this way, and either acquire laboriously, scrap by scrap, the preparatory knowledge which they are supposed to bring to the study of the profession, or else enter into the profession in gross ignorance.

We propose, therefore, that the first nine months at least of the student's time should be devoted to lectures on chemistry, botany, and physics, and elementary anatomy and physiology; that, so far as possible, he should not be entered for lectures on general anatomy, surgery, materia medica, or practice of medicine, or for clinical lectures in hospital until he has spent at least that period in such studies, and passed his first professional examination.

The student's mind having been disengaged from the preparatory studies above referred to, and being stored with the information necessary to his comprehension of the more advanced subjects, we propose that the next period of study should be devoted to making himself up in the full subjects of anatomy, physiology, practice of medicine, theory and practice of surgery, and other courses which are the groundwork of the practical work of the profession.

The time has now come to make himself thoroughly acquainted with the principles of medicine and surgery, and with the *minutiæ* of the structures with which, in practice, he will be engaged. His regional anatomy and histological physiology would now be thoroughly mastered, and his time devoted to acquiring a complete knowledge of the practice of medicine and surgery, and to pathology. For these studies, he would have two complete sessions, and will thus be enabled to offer himself for his second examination at the end of his third winter session, and by so doing, clear the ground for the devotion of his fourth year to actual eye and hand work of the hospital wards.

The nature of our scheme of education is sufficiently obvious to make it unnecessary that we should dwell longer upon the subject. We propose that the last period of education shall be strictly one of practical experience; we would have the student to devote his whole time to the manipulative surgery and diagnostic medicine of the hospital wards, and the pathology of the dead-house; to make himself fully conversant with therapeutics and prescription-writing, and the examination of urine with test and microscope.

Such a programme of study as we have sketched out would not be excessive either as regards the capabilities or the wants of the student, nor would it, we think, be at all difficult of arrangement, and we are convinced that if honestly followed out, it would ensure that the student would bring with him into practice a thoroughly competent acquaintance with his profession.

Notes on Current Topics.

A Statesman's Estimate of the Medical Profession.

In his Rectorial address, Mr. Gladstone adverted, among many other points of educational interest, to the position of medicine in the present time as a study and as a profession. What might have been expected from him he uttered—an eloquent exposition of the progress and aims of medical science; an earnest appeal to men, medical and lay, to acquaint themselves with the objects and details of professional work; and a vigorous defence of the nobility of the labours engaged in by those who devote their lives to the amelioration of the woes of the weak and diseased. At all times breathing inspiration in his addresses, Mr. Gladstone on this occasion was even unusually forcible, and it is not too much to expect that the real lively interest he has himself exhibited in the advance of medicine and surgery may be productive of the most important results hereafter. Though it is folly to expect that the lay mind can be awakened to the necessity for it to acquaint itself with the principles which guide the practice of professional men; yet it is a healthy and encouraging sign of improved appreciation of great truths, and the importance of their bearing on the general welfare, when the great leaders of public opinion deem it their duty to impress these truths on the mind of the nation. But the chief benefit derived is in the influence exerted on the actual students of the time. They cannot fail to derive increased enthusiasm from the expressions of one whose position and personal merits lend so heavy a weight to the words which fall

Digitized by Google

from him, and in this direction especially, the impetus thus afforded will lead to the most direct and permanent results. How far we may be permitted to hope for a brighter future on behalf of the all-absorbing question of reform must for the present be only a matter of speculation. That it will be influenced for good, however, is not an entirely unjustifiable opinion.

Antiseptic Surgery.

The adjourned debate on antiseptic surgery took place on Wednesday last at St. Thomas's Hospital. As might have been expected, no important change of opinion can be chronicled differing from that to which we have already given free expression. The discussion was of the most interesting kind, and important from the great eminence of those who engaged in it. The chairman of the meeting, Mr. John Wood, opened the proceedings, and though he eulogised Mr. Lister's character and energy, he did not express himself an adherent to his views. Mr. Hutchinson's testimony was decisively in favour of the adoption of antiseptic precautions in all cases where through them any possible danger might be avoided. He advocated the greatest care in determining the conditions under which the rules for dressing should be fully carried out, and expressed an opinion that "the gauze and spray" might even, sometimes, do positive harm. The truth of this is not, perhaps, so apparent to all as to Mr. Hutchinson, but we can understand the caution he would convey, though he possibly goes somewhat farther in his dread of carbolic poisoning than the antiseptic surgeon pure and simple would be inclined to follow him. Sir James Paget was inclined to attribute a large measure of modern improvement in surgery to improved sanitation, nursing, and treatment, but admitted that such operations as ovariotomy, osteotomy, incisions into joints, &c., should be done only under the spray, and with antiseptic precautions. He further ascribed the great merits of recent advances to Prof. Lister. Mr. Lund, of Manchester, and Dr. Newman, of Stamford, both avowed themselves strongly on the side of the antiseptic school. Mr. Morrant Baker charged the antiseptic system with many evils, and quoted statistics of non-antiseptic operations (with few exceptions) from which he drew conclusions favourable to the aqua-purist view. Mr. Knowsley Thornton and Mr. McCormac were the other speakers. The result of the debate will, we hope, be a good one; though it may not convert the non-believers, it may set them thinking, and possibly to good purpose.

Hospital Nursing.

We are glad to find that we have aroused an interest in the question of hospital nursing through the prominent notice we have taken of recent events in connection with a certain metropolitan charity. Certain of our contemporaries have readily accepted the suggestion our remarks contained, and have dilated on the question of "sisterhoods" in relation to ward-work. We are glad to be able to add our testimony in favour of employing women of a lower rank than those who are usually members of sisterhoods, to perform the more directly manual work of nursing. It is right and proper that the ister, or head of a ward, should possess the education, as well as the more refined and sensitive feelings of a lady, and by virtue of these can we expect her to discharge her duties with greater satisfaction to her employers, and greater advantage to her charges. It is above all things desirable to obtain the best servants for hospital work; and we must admit that a comparison of results obtained under the old system of trained nurses, and the more modern one of trained sisters, does not encourage faith in the latter. At Guy's Hospital the change has not been for the better. We are assured that the ladies from the sisterhood are excellent observers of temperature, of pulse, and of respiration; but that the more menial, though equally important details of attendance, they are absolutely inadequate to fulfil untaught. This is not what should be. If the ladies who join the sisterhood intend to *be* nurses they should qualify for every part of nurse's work, or they should be content to leave the office to be filled by such as are prepared to follow the whole duties of it, and fit themselves to perform them correctly. We freely admit that "sisterhoods" are an invaluable institution under proper guidance, but we as freely declare that they are, at this present time, conspicuously mismanaged, and are productive of far less benefit to the sick poor than they are capable of conferring.

Cresylic Acid in Whooping Cough.

Vapour of cresylic acid, produced by means of a simple evaporating dish over a spirit or other lamp, is said by Dr. John Merratt, in the *New York Medical Record*, to have a marked beneficial effect in pertussis. From the immediate ease experienced under its influence, and the facility with which the vapour can be produced, the remedy is deserving of a much more extended trial than has yet been made of it. An additional advantage it possesses is that it is in no way injurious to healthy persons, and is not to any extent disagreeable. A considerable extension of the use of this drug seems possible, for it allays the irritation of bronchitis, and overcomes the constant desire to cough. Cresylic acid (cresolene) has the composition HC_6H_5O (Phenol) + CH_2 and is a product of coal tar.

The late Dr. Maclure.

Another loss has been sustained by the medical profession through the death a few days ago of Dr. Maclure. After only a few days' illness he sank rapidly, and died at his residence in Harley Street. Dr. Maclure was for some time lecturer on physiology at the Westminster Hospital Medical School, and many who were his pupils will long remember him with affectionate regret.

A Hint for Drug Vendors.

A retail milk dealer (a poor woman), who had been twice convicted under the Adulteration Act, and paid the fines imposed, has recovered, in the County Court, Southampton, the whole amount from the wholesale dealer from whom she purchased the supply. The judge also awarded her 10s. for loss of time in attending before the magistrates. The course pursued by this poor woman is exactly that which chemists anddruggists might pursue if they were really guiltless of complicity in the adulteration.

Light Hues for Winter Clothing.

It would be well that our contemporaries, when writing sensational paragraphs for quotation in the lay press were a little more careful not to outrage the teachings of science and common sense. A week or two since a contemporary contained an annotation on the effects of colour on the radiating power of clothing. The views therein propounded were so erroneous, and were unfortunately so widely circulated by the daily papers, that in the interests of truth we cannot allow them to pass unchallenged.

Up to about fifteen years ago it was a matter of doubt whether colour did or did not regulate the absorption or emission of heat rays, but the experiments of Tyndall, in 1865, removed these doubts by showing most clearly that although the colour of a substance may materially affect the rate with which it will become heated by the luminous rays of the sun, yet "as regards the radiation and absorption of *non-luminous* heat, *colour teaches us nothing.*" (Tyndall's "Fragments of Science," vol. i., p. 90, 1879 edition.)

The experiments on which these opinions were based have, so far as we are aware, never been controverted, and in most text-books may now be found some equivalent to the following statement (from Ganot's "Physics," by Atkinson), viz, the colours have "no influence on the radiating power."

With regard to polar bears it would be hard to determine whether the animals are disciples of the exploded theory or not; but it is easy to conceive a reason for their colour, very different from that alleged. A "grizzly" on the snow, and a polar bear on dark soil, would be such conspicuous objects that the prey which fell into their jaws must be in as sleepy a state as the writer of the paragraph in our contemporary.

The Exodus of Nurses from Guy's Hospital.

In our issue of Nov. 26, we published a statement of the serious differences existing at this hospital by orders issued by the recently appointed matron: one of our contemporaries thought fit to assert that the statement was overdrawn, that it only concerned students, and that no serious difficulty existed.

In the last number of the *Guy's Hospital Gazette*—last in a double sense, for it contains an announcement that "its conductors will be unable any longer to continue its publication" under the restrictions attempted to be imposed by the treasurer—the editor concludes an article thus:—"We are happy in having received the treasurers, assurance that the changes shall in no way affect our (students') privileges. We wish, however, that a similar assurance had been extended to those who after years of active honest work find themselves face to face with a new system, inaugurated in a manner evidently intended to compel them to resign appointments that they have hitherto filled to the satisfaction of those of the staff who work for, or take interest in, the welfare of the hospital. But with this we shall be told we have no concern; and if the wholesale exodus of experienced nurses, the loss of sisters of well-tried efficiency, and the strongest efforts of the united staff are unavailing to alter matters, any representations which we could make would be fruitless. But with all due deference to the judgment of those in superior positions to ourselves, we would ask whether such sacrifices are atoned for by the retention in office of that power which has brought such things to pass."

St. John's Ambulance Association.

One of the most important improvements that has been introduced of late years into the police-force organisation is that by which the members of the force are instructed in elementary minor surgery. The men who have shown the greatest interest in the instruction given to them have in many instances acquired considerable aptitude in dealing with cases of injury; indeed, on more than one occasion, the conduct of individual members on emergency has been highly praised from the bench. The men are regularly taught now in classes, and many medical practitioners have given valuable assistance by personally superintending the working of the scheme. Last week certificates were awarded to two hundred of the Metropolitan and City police, who have passed a successful examination on the subject of the lectures and demonstrations they have been attending. The effect of these certificates is said to be a good one, and it is felt they will act as a stimulus to men to endeavour to fit themselves to be deserving of them. The movement is certainly a good one, and deserves all encouragement.

The Battle of the Forceps.

In a recent number of the *St. Louis Medical and Surgical Journal* we notice a paper, contributed to the Medical Society of that city by Dr. Thomas Kennard, entitled, "The Use and Abuse of the Obstetrical Forceps." We have had recently at the Obstetrical Society of London a discussion upon the value of these instruments, and it would seem as if the wave had spread across the Atlantic, stirring up the New World Obstetrical Societies into throes of labour, from which a bigger mouse may come than from the parent society in old England. At the Saint Louis Society a member read a paper stating that he used the forceps once in every three labours; and another member stated that he only used them once in every seven.

Dr. Kennard has rushed in to do battle against the modern knights-errant who, forceps in hand, and with a reserve of instruments of precision, armed *cap-a-pied* in every case of labour, make an excuse for the employment of their favourite instruments, and who thus made the female vagina a receptacle for the handiwork of the instrument maker and silversmith. His language is strong and forcible. The foibles of some of our gynecologists are well taken off. If Aristophanes were alive he would revel in such a subject; and there is somewhat of the old comedian's vein in Dr. Kennard's conclusions. "The battle of the forceps" is not yet over. It is well for us in England to hear the opinion of one of our American brethren, so we present them with a portion of Dr. Kennard's address:—

"We have waves in medicine and surgery that sweep everything before them, and wash every enthusiastic seeker for glory into the grand Maelstrom that engulphs them all. Twenty years ago every woman imagined that she had ulceration of the womb, and of course every

Digitized by Google

medical aspirant for fame insisted upon a look at that organ through the speculum.

"I well remember my first personal experience in that direction at a clinic of one of New York's most distinguished obstetricians, where some twenty of us, in Indian file, awaited our turn to take a peep at the women, many of whom had nothing the matter with them. . . . Five years later they imagined their wombs did not hang right, and through the influence of the misguided enthusiast, Dr. Hodge, who had revived an old and long forgotten idea, the young practitioner was inclined to make a toy-shop out of every woman's vagina, so that it became very questionable whether even refined and virtuous women had private parts any longer. Unfortunately a great many females manifested a morbid desire to be examined, and they encouraged the deep investigators in their dark researches. A few well-meaning men still imagine that it is incumbent upon them to prop up every womb, but fortunately their enthusiasm expends itself on their ingenuity in devising new vaginal toys, which not many women are now inclined to play with. The pessary wave has subsided, never again to return, except in spirts and splashes. Women have concluded that although their outside stays sometimes create a necessity for inside props, they still must entertain a decent respect for their private parts, the *sanctum sanctorum* of their physical organisation.

"Our instrument stores are full of pessaries, and it is very entertaining to see the ingenuity employed by some of our brethren of a mechanical turn of mind in varying their shape and size. We might well suppose that no two vaginas were constructed on the same plan if we did not know to the contrary. About the year 1867 the clitoridectomy wave threatened to sweep away the clitoris of every nervous woman who applied to the hospital of a London accoucheur who enjoyed the favour and patronage of royal folks, and had an idea—not a very incorrect one—that all cases of hysteria resulted from venereal cretinism.

"Neck splitomy was the next wave, but it soon subsided; and then impregnating by the syringe was tried, but it did not compete with the old plan, and no one but J. Marion Sims ever advocated it. The forceps wave returns periodically, and we must beat it back whenever it rolls too boisterously. Hence the few hurried words of caution I have read to you. Recently some surgeons have advocated and practised complete removal of the uterus and ovaries, and have taken only about seven lines to describe the method of this horrible operation in their fatal cases on patients who would have lived for years if they had not butchered them. More recently they have taken to spaying women as farmers do sow pigs; but as women were not intended for food except in dire emergencies, the great Creator did not see the sense of such mutilations, and hence the majority die from the operation. God protect the poor woman from the enthusiastic gynecologists and the extremists of every kind!"

The Ledwich School and the University of Dublin.

The following resolution was adopted by the Council at their adjourned meeting last week:—

1. That the following resolution of the Board respecting the Ledwich School of Medicine be approved of by the Council:—

Resolved—"That the Ledwich School of Medicine having applied to the Board of Trinity College for their recognition of said School of Medicine, and having communicated under the signatures of the proprietors and lecturers of the School that the following resolution had been, in order to obtain the recognition of Trinity College, unanimously adopted by the proprietors and lecturers of the School, viz.:—Resolved—'That we, the undersigned proprietors and lecturers of the Ledwich School of Medicine and Surgery, hereby guarantee that three-fourths of each full course of lectures delivered must be attended by each University student, in order to obtain the certificate of attendance, such attendance to be verified by a roll called at each lecture'—the Board of Trinity College, agree, on the faith of the above assurance and undertaking, to place the Ledwich School of Medicine and Surgery on the list of the medical schools recognised by Trinity College."

It will be recollected that the recognition of the certificates of lectures at the Ledwich School was withdrawn by the University Board because of the issue of certificates by an hospital which was supposed to have intimate relations with that school, such certificates being proved unreliable. While sympathising with Trinity College in its desire to put a stop to the sham certificate system, we felt bound—on that occasion—to protest against the disfranchisement of the school for the offence of which the hospital was believed guilty. However, it will be observed that the ban is now withdrawn and the school admitted to the same rights as those enjoyed by other schools. The University would have deserved greater credit for its action in the matter if it had included within its *index expurgatorius* other schools which were just as much open to suspicion as the Ledwich.

Unfermented Wine—a Cheerful Liquor.

At the Salford Court, one Pilling, a chemist, appeared recently in answer to a summons taken out against him under the Food and Drugs Act, 1875, for selling to the inspector two bottles of what purported to be "unfermented port and sherry wine, manufactured from the juice of the grape, and used for family and sacramental purposes," which wine, on being submitted to the borough analyst, was found to be not of the substance, nature, and quality demanded by the purchaser. The result of the analysis was that Mr. Bell, the analyst, found absent all the constituent parts which constituted the pure juice of the grape, and the liquid contained in the bottles was practically nothing more than coloured water. The so-called "unfermented wine" was sold in considerable quantities among total abstainers, and was said to be used largely for sacramental purposes. What the defence would be he could not conceive, unless the defendant confined himself to contending that he sold the liquid as he purchased it from the manufacturer. He reminded the bench, however, that the 25th section of the Food and Drugs Act provided that a person selling any adulterated article was liable to be fined unless he produced a written guarantee to prove that it had not been tampered with since the purchase took place.

The inspector said he did not actually ask the defendant to supply him with "the juice of the grape," but he expected when he made the purchase to get what was stated on the bottle, namely, "unfermented wine, manufactured from the juice of the grape."

The public analyst said he would not swear that there was not an infinitesimal quantity of the juice of the grape but the proportion was certainly not equal to 10 per cent.

In cross-examination, witness admitted that several of

Digitized by Google

the constituents which went to form the liquid purchased might have been contained in the juice of the grape.

Mr. Green submitted, in defence, that the liquid purchased by the inspector was really what it purported to be, namely, "unfermented wine," manufactured from the juice of the grape. It was not sold, or intended to be sold as pure juice of the vine, and therefore, the prosecution, he held, must fall to the ground.

Mr. Bell, one of the firm of manufacturers in Liverpool, said the wine was manufactured principally from grapes, and had a very large sale, there being no fewer than 3,284 wholesale customers for it. Fifteen Nonconformist churches in Bradford were supplied with the wine, and there was one chapel where a dozen bottles were drunk every Sunday.

Mr. Hewson, manager of Messrs. Bell's works, said he manufactured the wine and it contained one-sixth part of pure grape juice, and five parts of sugar and water, with a small quantity of burnt sugar for colouring purposes.

The Stipendiary said he was of opinion that the summons must be dismissed, inasmuch as it was not proved that the wine did not contain some portion of pure grape juice, and no standard was fixed by the law by which he could decide whether the proportion was sufficiently large or not to justify the sale.

Metropolitan Hospital Sunday Fund.

The annual meeting of the constituents of the Metropolitan Hospital Sunday Fund was held in the Egyptian Hall of the Mansion House on Thursday last. In the unavoidable absence of the President of the Fund, the Lord Mayor, Sir Rutherford Alcock occupied the chair. On opening the proceedings he said it must have been particularly gratifying to the clergy, as it was to the Council, to find, notwithstanding the depression of trade, and the distress so generally prevalent, combined with a wet day, that the total amount contributed by the various congregations exceeded that of the previous year by £1,696, the total amount actually received being £26,501 4s. 1d. The working expenses of the year had somewhat increased, and this arose from the circumstance of the compulsory removal of the secretary's office, and the cost attendant thereon. But it is hoped that the present Lord Mayor will once more grant them the use of an office, and save this additional outlay. No difficulty had arisen in the distribution of the fund. The few hospitals that had been invited to a conference had preferred to leave their cases in the hands of the Distribution Committee, thus showing the confidence reposed in this body. The sum of £25,221 8s. 2d. had been distributed between eighty-one hospitals and forty-six dispensaries; in addition to which £260 had been set aside for the purchase of surgical appliances, and which had already proved a boon to many sufferers amongst the hospital patients, whose maladies demanded prompt aid, and who otherwise must have been thrown upon such societies as the Surgical Aid, and compelled to tramp over London begging for a number of letters equivalent in value to the cost of instrument, thus creating a scandal no less offensive to humanity than it was detrimental to the cause of true charity.

In a few well-chosen words of thanks and praises, the Rev. Mr. Bristowe moved the re-appointment of the Council for the ensuing year, and on the motion that the existing laws of the constitution of the fund be continued, a reverend gentleman expressed a hope that the Hospital for Incurables should in future partake in the distribution of the fund. It was, however, very strongly urged that this institution is to all intents and purposes an asylum, and not an hospital, and, more than that, it is a voting charity. After some discussion it was agreed to relegate the question to the Council for them to consider and report upon at the next annual meeting. On the motion of Bishop Claughton the next Hospital Sunday was fixed for the 13th June, 1880.

Anatomo-Pathological Researches on Hydrophobia.

Dr. Brigidi (*France Médicale*) has noticed the following pathological changes:—Great hyperæmia of brain and spinal cord, as well as membranes, and in one case serous effusion in the subarachnoid spaces. Enlargement of the cerebral and medullary cells, which were found to be full of vibrios. Similar appearances were found in the blood, mixed with bacteria, and extensively marked in the circumference of the vessels. The central medullary canal was distended, and full of the same granular substance.

Dr. Brigidi does not pronounce on the question as to whether the development of the vibrios has been a cause or effect. He believes that the morbid process observed in the nervous centres is of an irritative and degenerative nature, and that under the influence of the vibrios it may spread with extreme rapidity.

Lady Doctorates.

Two ladies have just received the degree of Doctor of Medicine in Paris. One of these ladies is Mrs. Chaplin Ayrton, wife of the Professor of Applied Physics at the City and Guilds of London Institute. Mrs. Chaplin Ayrton commenced the study of medicine at the University of Edinburgh; but, owing to well-known occurrences her studies there were interrupted, and she recommenced them in Paris. The title of the thesis she presented to the Faculty of Medicine before obtaining her degree was "Recherches sur les Dimensions générales et sur Developpement du Corps chez les Japonais,"—she having accompanied her husband in a visit to Japan. Mrs. Marshall was also one of the Edinburgh lady medical students, and had to start afresh in Paris. The subject of her thesis was "The Influence of Sex in the Production of Mitral Stenosis"; and it is said that she proved to the satisfaction of her judges that the disease is much more common in women than in men. Mrs. Marshall is a sister-in-law of Mrs. Garrett-Anderson, M.D.

Last week the Court of Appeal refused the application for a new trial in the cause of Phillips *v.* the South-Western Railway Company. It will be remembered that Dr. Phillips was injured on the defendants' line and received a verdict for £8,000,; this he considered insufficient, and upon a second trial got this increased to £16,000. The decision of the Court of Appeal confirms the latter finding.

Strychnia Poisoning Treated with Chloral Hydrate.

Dr. C. M. Worthington reports, in the *Pacific Med. and Surg. Journ.*, a case of strychnia poisoning treated by electricity to relax the spasm of the facial muscles so that liquids could be swallowed; by half-drachm doses of Llebreich's chloral hydrate and one dose of one-quarter grain of apomorphia hypodermically. The patient recovered. The chloral hydrate was given every two hours.

The Actonian Prize.

The Managers of the Royal Institution of Gt. Britain have awarded the Actonian Prize of £105 to Mr. G. S. Boulger, F.L.S., F.G.S., for an essay on the "Structure and Functions of the Retina in all classes of Animals, viewed in relation with the Theory of Evolution."

Sir George B. Owens, M.D., J.P., has been chosen to fill the office of High Sheriff of the city of Dublin for the year 1880.

Captain Richardson, the leading partner in the well-known firm of John Richardson and Co., manufacturing chemists, Leicester, has been added by the Lord Chancellor to the list of magistrates for the borough of Leicester.

A new pharmacopœia has been published in Norway, but it is little more than a new edition of the Pharmacopœia of 1870, with a few modifications. A Pharmacopœia Scandinavica is in course of preparation, which will be used throughout Denmark, Norway, and Sweden.

Whatever be the cause, the Army Medical Service has suddenly become popular with the younger branches of our profession. At the examination held a few days since, there were actually more passed than there were vacancies for. In proof of this we need only refer our readers to the long list of candidates in our "News" columns.

The death-rates from the seven principal zymotic diseases in the principal large towns last week ranged from 0·5 in Brighton, and 1·2 in Portsmouth and Norwich, to 5·6 in Plymouth, 6·3 in Dublin, and 8·3 in Liverpool. Scarlet fever showed the largest proportional fatality in Newcastle-upon-Tyne, Dublin, Liverpool, and Bristol; and measles in Nottingham, Liverpool, and Plymouth. Small-pox caused 3 more deaths in London, 2 in Dublin, but not one in any of the other large towns. There were 777 deaths in London from affections of the respiratory organs.

Surgeon-General C. A. Gordon, M.D., C.B., with the sanction of the Government of India, has offered a prize of 500 rupees to the writer of the best essay on fevers as affecting the British soldiers serving in India. The competition is open to all medical officers of the British and Indian Medical Departments of the three Presidencies, retired, or on full pay, if on the 31st of August they had severally served five years or upwards with British troops. The essays are to be sent in by the 31st of December, 1881.

In the principal foreign cities the rates of mortality, according to the most recent weekly returns were—in Calcutta 26, Bombay 31, Madras 38; Paris 28; Geneva 19; Brussels 31; Amsterdam 25, Rotterdam 20, The Hague 23; Copenhagen 35; Stockholm 20; Christiania 21; St. Petersburgh 31; Berlin 23, Hamburg 26, Dresden 19, Breslau 25, Munich 33; Vienna 27; Buda-Pesth 27; Rome 38, Turin 27; Alexandria 32; New York 24 per 1,000 of the populations. Small-pox caused 28, and typhoid fever 28 deaths in Paris.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

Death-Rate of Glasgow.—The severity of the recent weather has been made very manifest in the suddenly increased death-rate in this city. For the week ending December 13th, it amounted to 31 per 1,000 of the population per annum, against 30, 25, and 22 for the corresponding periods of 1878, 1877, and 1876.

A Family Poisoned by Eating Sausages in Greenock.—On Saturday, the 13th inst., information was given to the police of a shocking occurrence at 35 Cathcart Street, Greenock. From inquiries made it appears that an old woman named Kerr, residing with her daughter, and Mrs. Ward and family, at the place above mentioned, was following her usual occupation of "middenraking," when she found a quantity of sausages. On her return home she stated that she had found them, and they were duly cooked, the old woman, Mrs. Ward, and her five children partaking of them. Soon afterwards Mrs. Ward complained of feeling unwell, as also did the children. Mrs. Kerr, strange to say, was not affected till late the following day. Mrs. Ward was completely prostrated, and, in fact, she and her mother and children had a most painful night, and everything that could be done to relieve their suffering was done by Dr. McDougall. Although the greatest attention was paid to her, Mrs. Kerr only survived till morning. On Sunday Mrs. Ward and her family were progressing favourably, and no fear is entertained of their ultimate recovery. On Monday a post-mortem examination of the body of Mrs. Kerr was made. The event has caused great consternation in the neighbourhood, and throughout the town. The post-mortem examination revealed no poison, but indications of death from eating putrid meat. The others are progressing favourably.

Glasgow Samaritan Society.—On the 15th inst., the annual meeting of the Samaritan Society in connection with the Western Infirmary was held in the Religious Institution Rooms, Professor Roberton presiding. Mr. Rutherford submitted a report, which stated that there had been 501 cases relieved since last January, and that a large quantity of clothing had been distributed to patients. There had also been 54 convalescents sent to the Dunoon Home, 20 to Kilman, and 5 to Saltcoats. The report was adopted, and office bearers appointed.

Aberdeen Royal Infirmary and Out-door Patients—A Commendable Resolution.—The question regarding the large increase of out-patients from all quarters of the city, including the dispensary districts, now asking advice and medicine at the Infirmary, came up for consideration at a special court of the managers of the hospital held on the

Digitized by Google

15th inst. Dr. John Urquhart, who at the previous meeting had submitted an amendment on Lord Provost Jamieson's motion for the unqualified adoption of the report by the committee of management, said that as the amendment of which Mr. Francis Edmond, advocate, had given notice at last meeting of the court, left all that he desired should be left to the direction of the medical officers of the infirmary, he would now withdraw his amendment in favour of that of Mr. Edmond. The Lord Provost said that since there seemed to be a feeling in favour of Mr. Edmond's amendment, he, too, would withdraw his motion, and allow the question to go back to the committee of management in that form, although he felt quite convinced that the recommendation embodied in Mr. Edmond's amendment was impracticable. Professor Struthers also withdrew in favour of that of Mr. Edmond, which was after discussion agreed to as follows, viz., "That the Court having considered the report by the Committee of Management, submitted to the Quarterly Court on 10th March last, along with the opinions previously and since obtained from members of the medical staff and the superintendent; and having also considered the existing regulation of the infirmary, that no person can be received as an out-patient who resides within the boundaries of the Aberdeen Dispensary, along with the agreements between the managers of the infirmary and the directors of the dispensary, all relating to out-door patients; and keeping in view the terms of the late Mr. Burnett of Den's bequest, resolves that the said regulations and agreements be adhered to and confirmed; with this qualification or explanation that the medical officers, in their turns, after giving in the first place the usual time and attention to their in-door patients, and in the second place advice and a card for medicine in the infirmary to in-door patients beyond the dispensary boundaries, may, in the third place, give advice in special cases to out-door patients within the said boundaries if not on the poor's roll, and a card entitling them to receive medicine from the dispensary, but only on condition that every applicant produce an application and recommendation, and a declaration of inability to pay, all in the terms reported by the committee of management; and on this further condition as to the said special cases, that they are recommenned by a professional person as serious cases, and be reported as such by the medical officer to the superintendent of the infirmary." In unpleasant contrast to the wise spirit of the above resolution is the custom at the Royal Infirmary of Glasgow, where advice and medicine are given *indiscriminately* to all comers, and a system thus fostered and encouraged which is a scandal to the city, and a flagrant injustice to its medical practitioners.

Registrar-General's Returns.—The weekly return of births, deaths, and marriages says:—The death-rate in the eight principal towns during the week ending with Saturday, the 13th December, 1879, was 28·0 per 1,000 of estimated population. This rate is 1·9 above that for the corresponding week of last year, and 4·6 above that for the previous week of the present year. The lowest mortality was recorded in Greenock, viz., 16·9, and the highest in Paisley, viz., 46·8. The mortality from the seven most familiar zymotic diseases was at the rate of 3.6 per 1,000, being slightly above the rate recorded for last week. The increase can only be attributed to the number of deaths from whooping-cough, which was rather prevalent in Glasgow. Acute diseases of the chest caused 243 deaths, being an increase of 66 on the number recorded during the previous week. An increase was observed to a greater or less extent in all the towns, except Greenock and Perth.

Royal Scottish Academy.—Professor Turner, Honorary Professor of Anatomy to the Royal Scottish Academy, delivered last night the second of two demonstrations in the Life School. At the outset of the lecture the professor explained that for the greater part of the time he intended to direct attention to the hand, a part of the body which was especially human. Apes had, he said, undoubtedly hands, but the hands of these animals were very imperfect indeed as compared with the human hand. At the close of an interesting address Professor Turner indicated that if time permitted he proposed to deliver two more demonstrations in the course of the session. The professor was accorded a hearty vote of thanks on the motion of Sir D. Mackee.

Action against a Galvanist.—At the Edinburgh Sheriff Court, on the 17th inst., Sheriff Hallard heard proof in an action against Dr. Kintoul, Leith. In April of last year, John McLay, sawyer, pursuer, was stabbed in the right arm-pit, in consequence of which his forearm and hand had become paralysed and devoid of sensation. With the view of having the muscular power of the injured limb restored, he consulted the defender as to the application of galvanism or electricity, by means of which, he alleges, he was assured of a cure in a very short time. The pursuer, believing the representation of the defender, allowed him to apply galvanism by means of a galvanic battery, and he avers that in the course of the operations the defender ignorantly and recklessly placed the injured hand in a vessel of boiling water, and allowed it to remain there for about half-an-hour, with the result that when taken out the skin peeled off, the tissue was found to be destroyed, and mortification ensuing, amputation had to be resorted to. For such alleged unskilful treatment pursuer claimed damages to the extent of £150. Several eminent Edinburgh physicians were examined for pursuer. At the close of the proof the Sheriff made avizandum.

Faculty of Physicians and Surgeons, Glasgow.—The Widows' Fund.—The Faculty of Physicians and Surgeons of Glasgow promote a bill before the House of Commons for regulating the management of their widows' fund, for authorising a transfer of the fund and its liabilities, and for winding up the fund. It is proposed that from the passing of the Act no new contributors shall be admitted; and powers are sought to elect as trustees persons not contributors, and reduce the number of trustees; to appoint a judicial factor; to vest the property and obligations of the fund in new trustees and judicial factor; to contract for the transfer of the fund and its liabilities; to contract for the purchase of annuities and provisions for widows and children of deceased contributors, and divide the remainder of the fund among surviving contributors, and to agree with contributors desirous of retiring from the fund.

Glasgow Maternity Hospital.—Dr. Samuel Sloan has been appointed Physician-Accoucheur in room of Dr. Tannahill, resigned.

Stirling.—Death of Dr. Beith.—Dr. Andrew Beith, the oldest medical practitioner in the Stirling district, died at his residence in Craigs, Stirling, at the age of 78. About two months ago Dr. Beith was thrown out of his gig, and was so severely shaken that he was able to be out only once after the accident. Dr. Beith for many years was parish medical officer and physician to the Combination Poorhouse, and until very recently he held the office of burgh medical officer under the Public Health Act. Dr. Beith was highly respected, and his death causes a blank in many circles in Stirling, where he will be much missed.

Literature.

THE PRINCIPLES AND PRACTICE OF GYNÆCOLOGY. (a)

"This work is essentially a clinical digest. It includes the result of my individual experience." Such are the opening words of the author's preface, and a perusal of the work enables us to say that they are perfectly true. Dr. Emmet's work is essentially a record of his clinical practice, well told and clearly expressed. After a review of the "The Relations of Climate, Education, and Social Conditions to Development," the author devotes four chapters to consideration of "The Instruments used in Examination," "Surgical Appliances," "Modes of Examination," and "Causes of Disease." These chapters occupy 93 pages. Then follow chapters on "Principles of Treatment," &c., "Pelvic Circulation, and Applications to the Uterus," some 50 pages more. Nearly 100 are then occupied by the consideration of "Ovulation and Menstruation," "Abnormal Changes in the Menstrual Flow, and Congenital Malformation of the Vagina," "Pelvic Cellulitis," "Displacements of the Uterus," and their treatment, "Flexures of the Uterus," "Prolapse," "Laceration of the Perineum," and "Subinvolution," are then considered. "Inversion" and "Cancer" are treated in separate chapters. Two more are devoted to the consideration of a subject to which Dr. Emmet give great prominence, namely, "Laceration of the Cervix Uteri." Quite a third of the volume is allotted to the surgical treatment of uterine and ovarian disease, including that of fibrous and ovarian tumours, the various forms of fistulæ, and the author's special favourite, that of laceration of the cervix uteri, which are not of infrequent occurrence after labour, especially if the forceps have been used before the os has been fully dilated.

From this *resumé* it will be seen that the surgical treatment of disease occupies a very prominent place in the work. Indeed, it is as a record of the author's views in the department of "Uterine Surgery" that the work is specially valuable. Dr. Emmet is a gynæcologist of great experience; his book contains much that is valuable, and not a little that is novel. The chapters devoted to the treatment of "Laceration of the Cervix Uteri" come under this heading, for although Dr. Emmet, as long ago as 1862, published a paper on this subject, his views are as yet but little known on this side of the Atlantic.

"32.80 per cent. of all women under my observation (in private practice during five years) who had been impregnated, and had suffered from some form of uterine disease, were found to have laceration of the cervix." Such is Dr. Emmet's experience, *vide* page 447. A little further on he adds, referring to his tables, "it is to be noted that two instances of laceration occurred from miscarriage, and ten as a consequence of criminal abortion," a statement which reveals a melancholy picture of the morality of women in America. In reference to the subject of laceration Dr. Emmet makes a remark which it would be well that those engaged in midwifery practice here would bear in mind. He says, "it is evident there are some who are in the habit of delivering with the forceps without apparently the slightest reference to the stage of labour." We fully endorse Dr. Emmet's inference that to this most reprehensible practice the consequences he describes are frequently traceable, a practice, we regret to say, advocated by some practitioners even in this country.

Starting from these premises, Dr. Emmet proceeds to build up his theory, which, briefly stated, is this, that until lately this condition of laceration was *universally* mistaken for ulceration, and sometimes for the early stages of epithelioma, and for corroding ulcer of the uterus; and that for its cure he considers an operation necessary, notwithstanding in many cases that the parts may have completely healed.

We are most unwilling to analyse critically the phraseology used by Dr. Emmet, but in the present instance we feel that it is our duty to point out that in treating this subject he has been so carried away by a single idea that he is betrayed into not a few inconsistences and errors. The sentence we have just quoted is an instance. How can "the condition of laceration" have been "universally" mistaken for ulceration if it has also been mistaken for epithelioma? While to say that it was universally so, is to bring a sweeping charge of, at once, ignorance, stupidity, and gross carelessness against the whole profession.

It would be impossible for us in our limited space to analyse as we would wish the tables and facts so carefully brought together on this subject by Dr. Emmet. We shall briefly refer to his treatment. To quote his own words, "the chief purport of the treatment is to bring about union of the lacerated surfaces, and the question naturally presents itself as to the circumstances under which an operation is called for. I would state that in every instance where the condition is evident, and where enlargement of the uterus still remains, or where the woman suffers from neuralgia, I consider the operation necessary, notwithstanding the parts may have completely healed."

From this it is evident that the operation is, in Dr. Emmet's opinion, very frequently called for. The operation is then described at length. The edges are to be denuded, carefully brought together, and held in close contact with silver wire sutures.

Much stress is laid on preparatory treatment, and it is laid down as a rule that "so long as there can be detected, by pressure with the finger, any tenderness in the neighbouring connective tissue, it is not safe to operate."

In concluding our reference to this subject we must add that, in our opinion, this operation is, in some cases, of much value, but that Dr. Emmet appears to us to practise it too frequently, and certainly lays undue stress on lacerations of the cervix. As a proof we may quote his opinion, page 493, "that nearly all, if not all, cases of epithelioma, or cauliflower growth, have their exciting cause or origin in a laceration of the cervix." We have seen a goodly number of cases of this disease occurring in women who have never been pregnant, and believe this statement to be quite erroneous.

The chapter on inversion of the uterus contains a *resumé* of the various methods of treatment in practice. Perhaps the most valuable suggestion it contains, and one which we believe to be original with our author, is, that when the fundus has been passed within the os uteri, but that the further reduction is impossible, "that the fundus be confined within the uterine canal," an opening being left to permit the escape of the menstrual flow; "but before resorting to denudation for bringing about permanent closure, that sutures alone be employed. This gives the opportunity of making another attempt at reduction if Nature fails to accomplish it."

The whole book deserves an attentive perusal. It is an admirable exposition of the present state of uterine surgery from the pen of a talented gynæcologist, and will tend, we believe, to advance this important branch of surgery. It is not so suitable to the general practitioner, who has neither the time for, nor means of, performing the troublesome and tedious operations it treats of, and he will not find in it clear and concise directions for the treatment of the ordinary forms of uterine disease which are of such common occurrence.

(a) "The Principles and Practice of Gynæcology." By Thomas Addes Emmet, M.D., New York. London: J. and A. Churchill.

Literary Notes and Gossip.

Dr. Arthur Hill Hassall has just published a small work on "San Remo and the Western Riviera, Climatically and Medically Considered." He has produced a pleasant and readable book, and from the general style and binding, the work seems to be intended for the drawing-room table. We have seen Dr. Hassall's name in connection with almost every article of food, and always decidedly in favour of it; not so by his fault but that of the system on which public analysis has been hitherto conducted. In his new *rôle* he will probably be quoted as much in favour of "St. Remo."

* * *

Almost simultaneously with Dr. Hassall's work, we were favoured with a copy of another by Dr. Sparks, bearing a similar title, "The Riviera," &c., and with similar objects, viz., the attraction of English visitors to the shores of the Mediterranean. The papers originally appeared in the *Medical Times*, but have now been re-written and extended to a crown 8vo of 400 pages. Dr. Sparks is not so well-known to the public, and for that reason his book will not probably sell to the same extent as Dr. Hassall's; it nevertheless contains a good deal of interesting matter, and for such as are bent upon spending the winter on those shores, no better guide will be found. We think, however, that

Digitized by Google

patients will do better, at least this winter, by staying at home, the cold being unusually severe, and the snow excessive on the shores of the Mediterranean.

* * *

THE new library hall of the New York Academy of Medicine, which was formally opened last month, cost 9,556 dollars. The entire real estate owned by the Academy now amounts to about fifty-two thousand dollars. Its library contains upwards of ten thousand volumes, and its tables upwards of ninety medical periodicals. When it moved into its present quarters at the beginning of the present year, its library amounted to five hundred volumes only. The new hall is described as a model for society purposes, convenience, light, and ventilation.

* * *

LONDON has lost three valuable citizens during the past few weeks, and the profession three of its best known members, by the decease of Mr. Callender, Mr. Harry Leach, and Mr. Soelberg Wells. The latter gentleman was perhaps the best known in literary circles, his work on "Long, Short, and Weak Sight" and his "Treatise on Diseases of the Eye" being quoted as authoritative in almost every civilised language Mr. Harry Leach's literary labours were of a humbler kind, but not less successful; his "Ship Captain's Medical Guide," published under the authority of the Board of Trade, has passed its seventh edition; and the second edition of "The Pocket-Doctor" is well nigh exhausted. He was also the writer of the chapter "On Scurvy," in Cooper's "Surgical Dictionary." Mr. Callender's only literary effort beyond papers to medical journals and Societies' Transactions, was an essay "On Femoral Hernia,"

* * *

DR. HY. DAY, of Stafford, has published in pamphlet form his paper, "Observations and Comments on Certain Convulsive Disorders," which was read before the Medical Society of London. It is an interesting record of an experienced practitioner's observations on Chorea, Paralysis Agitans, and Epilepsy.

* * *

WE too often hear of persons being taken up by the police for being drunk and incapable, who are in reality suffering from some form of disease classified under the very broad and comprehensive term, "fits." There is great difficulty in the diagnosis of such cases, and much indignation has been unjustly vented on the police. Dr. Hedge Waters has published a small *brochure*, "The Treatment of Fits," to serve as a kind of guide to divisional police surgeons, and to assist them in diagnosing such complicated cases. From his experience in connection with the Metropolitan Police, he is enabled to speak with a certain degree of authority; as his work is principally based on typical cases which he has seen. We trust that his pamphlet will be widely circulated amongst the police force, for it may prevent many serious mistakes being made, and many a life may be saved by the adoption of the measures therein recommended.

* * *

WE have been favoured with copies for review of both the Carmichael Prize Essays, which we hope to notice later on. Mr. Rivington's work, to which the first prize was awarded, is one of such stupendous research, that it will require much close reading to do justice to its contents. Dr. Laffan's work, though less pretentious, is, from a cursory examination, fully entitled to the position it achieved among the twelve competitive essays.

* * *

A FEW days since there died at Herne Bay, whither he had retired from a busy London practice, at the ripe age of 82, Mr. Thos. Hunt, a member of our profession, whose literary efforts a few years since attracted considerable attention from the facetious portion of the lay press. "Hunt on the Skin," was too much for *Punch's* sense of the ridiculous to resist. "'Hunt on the Skin,' 'tis too bad to be thus instructed publicly in newspaper advertisements; it would be shocking in cold weather, in hot—bah! it makes one feel creepish all over. Gentle reader, whenever you see this reminder in the literary announcements, 'Hunt on the Skin,' take *Punch's* advice and don't." Hunt's little book was certainly illustrative of the familiar query, "What's in a name?" By it, the treatise—one not of the highest order of merit—sold extensively, and the author made a considerable practice.

* * *

MEMORIAL orations, though common in France, are rare occurrences in English-speaking countries, and this rarity adds greatly to their value and significance. Dr. Ephraim McDowel, of America, has well-deserved this honour, and his name will descend to posterity as the father of ovariotomy, an operation which has added so much to the honour of modern surgery, and still more has added many years of life to hundreds of women, who would otherwise have died at an early age. Dr. Gross has done justice to his memory in the oration before us, and all who are interested in ovariotomy should read this record of the work performed by the pioneer of the operation which has been brought to such perfection by surgeons of our day.

* * *

THE translating and editing of the valuable series of Professor Witkowski's "Movable Atlases" is being gradually completed. The last part is "The Eye and the Mechanism of Vision," the text of which has been translated, and in many parts re-written by Mr. Henry Power, F.R.C.S., a name which will carry accuracy and thoroughness with the work. The three remaining parts have, we understand, been undertaken by Dr. Stretch-Dowse, "The Brain;" Dr. Campbell Black, "The Male Genital Organs;" and Mr. Lennox-Browne and Mr. Hy. Sevill, "The Ear" and "Teeth" jointly.

* * *

WE have received parts viii. and ix. of Klein's "Atlas of Histology," and are pleased to notice that the latter parts fully sustain the promise of the initiatory number. The subjects included in the parts before us, comprise the blood-vessels and lymphatic glands, the teeth, salivary glands, oval cavity, pharynx, œsophagus, and stomach. The accompanying plates illustrating these chapters, do great credit to the artistic skill of Mr. Noble Smith.

* * *

THE representative of the Edinburgh College of Surgeons on the General Medical Council, Dr. Andrew Wood, is not only a distinguished physician and a good debater, but a poet of no mean order. True he has published no original poems, at least, so far as our knowledge goes, but he has translated and put into excellent English metre, several of the noblest classical works of Horace, Schiller and Lessing, and now comes forward with a volume of poems, eminently fitted for Christmas-tide. Dr. Wood has chosen Schiller's "Lay of the Bell," and other forms, as his latest effort, in which he fully establishes his reputation for lyrical elegance and ease. This work of Schiller is eminently open to treatment, it is full of sound philosophy and structural melody, and as the translator has adhered consistently to the text, the charm of the original is well preserved in its English dress.

* * *

IN our last column of "Literary Notes and Gossip" we mentioned with regret that our contemporary, *Guys Hospital Gazette*, had been placed under the inquisitorial control of the Treasurer to the Hospital, and that nothing would in future be permitted to enter its pages without first undergoing supervision. Such a state of things is, of course, incompatible with honest journalism, and this week the humiliating announcement is made by the editors of that journal, that "under the circumstances they will be unable any longer to continue its publication." That such an abuse of power should be possible in this age! that a layman should be allowed to gag the press, in order to suppress opinions contrary to his narrow-minded bigotry is simply astounding! Whilst congratulating the editors of *Guy's Hospital Gazette* upon their determination, the question arises what will the staff do?

* * *

THOUGH Radical in its political bias, there is practically no medical journal more conservative in its management than our contemporary the *Lancet*. The oldest of existing medical periodicals, it is the last to give way in modern improvements. 'Tis now many years ago—we hardly like to say how many—the *Medical Press and Circular* led the way in the cutting of its edges; one by one the others followed suit, and the *Lancet*, true to conventional tenets, is at last unwillingly dragged by the force of professional opinion it cannot afford longer to resist, to promise a similar concession to its readers in the new year. We congratulate our elder brother upon its reformation in this particular, and although differing from its "close-borough" style towards correspondents holding contrary views, we nevertheless wish it many another jubilee of useful and vigorous life.

* * *

IF all the Sunday lectures are to be of the same calibre as the one by Dr. Maudsley, there must be a greater number of intellectual men amongst the working classes of London than

Digitized by Google

we imagined. For in a few pages, "Lessons on Materialism," he deals with questions which have agitated the greatest minds in every age and in every country. We all know the well-known lines in reference to Berkleyism,

"What is mind? No matter.
What is matter? Never mind."

We are not satisfied with this couplet, and hence we are striving to clear up the problem. Dr. Maudsley's address is a temperate exposition of Materialism, and we wish his example could be copied by his theological opponents.

* * *

Our usual parcel of Messrs. Cassell's works for the current month are as interesting and as well produced as ever. "The Countries of the World," by Dr. Robert Brown, has reached the end of its fourth volume, and the author has travelled with his readers into the habitat of one of the most interesting nations on the earth—the Japanese. The number opens with a beautifully-executed engraving of a ferry-boat, containing five Celestial beauties, and drawn by six swimmers, harnessed to the boat like the geese to a clown's tub. The number also contains a historical narrative of the Philippine Islands, and is full of admirably executed cuts.

* * *

"The Great Industries of the World" reaches its 23rd part, and will be completed by its 30th. It concludes an interesting article on miners and their diseases, and one on calico printing, continues others on tile-making, on leather work, on big guns, on jute, and on steam navigation, and commences one on potters and lead workers and their diseases. The whole number is admirably illustrated and, irrespective of its educational value, it and the preceding numbers of the work must serve an important purpose in forcing upon the British artisan the conclusion that if our country is to maintain its manufacturing industries against foreign rivalries, he must be prepared to work as hard, and content himself to fare no better than his American and Continental competitors.

* * *

"Science for All" for the month opens with a coloured frontispiece of a group of corals, the description of which forms the first article in the number. Then follows an article on burnt-out volcanoes, by Professor Bonney, one on celestial objects viewed with the naked eye, the colour of the sea, and on Flowering. Each and all of these subjects are dealt with in the most attractive popular form, sufficiently superficially to be interesting to the commonplace reader, sufficiently accurately and scientifically to be instructive and useful as an item of education. The illustrations are abundant and excellent.

* * *

"The Practical Dictionary of Mechanics" has reached the end of the letter H, and gives short historical and explanatory notices, with profuse illustrations of every conceivable piece of mechanism within that alphabetical limit. It is superfluous to praise the turn-out of these works or their literary style. They are in all respects excellent, and we are pleased to believe that the enterprising firm of Cassell, Petter, and Galpin are abundantly rewarded for their speculativeness in issuing such useful and admirable educational works.

* * *

New Books and New Editions.—The following have been received for review since the publication of our last list, Nov. 19th:—"Notes on Fever Nursing," by J. W. Allan, M.B. "How to Use a Galvanic Battery," by Herbert Tibbits, M.D. "Clinical Lectures on the Diseases of Women," by J. Mathews Duncan, M.D. "The Royal Guide to the London Charities, 1879-80," by Herbert Fry. "Manual of Skin Diseases," by Malcolm Morris, M.R.C.S. "The Royal London Ophthalmic Hospital Reports," vol. ix., part iii. "Psycho-physiological Training of an Idiotic Hand," by E. Seguin, M.D. "Health and Comfort in House Building," by Drs. Drysdale and Hayward. "Annual Report of the Sanitary Condition of Wandsworth." "Klein and Smith's Atlas of Histology," parr ix. "Dislocation of the Hip," by Oscar H. Allis, M.D. "The Treatment of Hepatic Disease," by Wm. Stewart, M.D. "The Lay of the Bell, and other Poems," by Schiller; translated into English Metre, by Andrew Wood, M.D. "The Influence of Colloids upon Crystalline Form and Cohesion," by W. Miller Ord, M.D.

Correspondence.

ANTISEPTIC SURGERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In your leading article on Antiseptic Surgery of December 17th you have so inexplicably misinterpreted the remarks I made upon the subject, at the meeting of December 3rd, that I must beg of you to give prominence to the following correction:—

You state in the article referred to, with perfect correctness, "that Mr. Bryant declared himself unwilling to yield the whole glory of modern surgical improvement to the influence exerted against disease by antiseptic treatment, had, whilst admitting that vast changes had come over the methods of dealing with wounds, with their dressing, and all subsequent treatment," *you add most incorrectly*, "he yet strenuously resisted the ascription of any part of this improvement to the antiseptic agent *per se;*" adding *correctly* further on, "to the excellence of modern hygienic arrangements, to the better comprehension of the conditions and etiology of disease, to a keener appreciation of pathological transformations, and the influence of these on morbid changes, to the detailed observance of nursing and dietary minutiæ, would Mr. Bryant ascribe the vast improvement that all bear witness to;" but you again add *most incorrectly* that to these *alone* would I give credit; whereas, Sir, the truth is that I expressed my decided opinion that the introduction into practice of antiseptics by Mr. Lister was the last and crowning triumph of surgical improvement, and I thanked him warmly for their introduction. Indeed, I claimed to be an antiseptic surgeon as much as Mr. Lister, although I may not use the spray, and asked emphatically if any other antiseptic system existed outside the spray system or Listerism.

To this question I did not obtain an answer, but I live in the hope that in the course of time such a favour will be granted.

Your remarks upon other portions of my observations are equally misleading and inaccurate, and particularly those respecting the table of operations which I ventured to criticise, for that table which you describe "as being in number so limited and in detail so meagre" was published by Mr. Lister's right-hand man, with Mr. Lister's permission, and from his note-books, with the view of satisfying the reasonable wish that has been frequently expressed that a statistical account of some of the results of the antiseptic method of treatment in Mr. Lister's own hands should be published. The series, moreover, contained, as the reporter describes, a *selected series of cases*, which must be looked on as *crucial tests* of the treatment, and included *all* Mr. Lister's operations on healthy joints performed under the spray (a period of eight years), together with such accidental wounds of joints as occurred during the same period.

This table, which you describe as so limited in character and so meagre in detail, I deemed worthy of criticism, and on Mr. Lister's behalf would ask you to condescend to study it, for the careful study of authentic facts such as these tends towards accuracy, and does as much to suppress rash assertion as to give precision to practice.

I will not, however, venture to repeat here all the criticisms I made at the meeting you refer to, although I may express the surprise I felt when I found the oft-repeated assertion that "loose cartilages may *now* be removed by direct incision from the knee without any apprehension of evil results" was based upon the experience of only *three* cases, and another assertion, no less striking, "that a joint may be cut into with the *certainty* that no danger will follow, with perfect safety, and without risk," was based upon the limited experience of another sixteen cases. This surprise was also much enhanced when I read that several of these sixteen cases were of a very trivial nature, some of the others were good in their results, a few bad, and the remainder satisfactory; the whole, when read without a bias, possibly suggesting that the practice which had been adopted

Digitized by Google

in their treatment was good, but no more. They certainly by no means afforded conclusive evidence as to its advantages.

These, Sir, were the chief criticisms I made, and which I now repeat, for I maintain that more good is to be gained by freedom of speech, when employed with the honest wish to arrive at truth, than by disturbing facts or building up temples of assertion upon limited data; and that "antisepticism" has done too much good in the practice of surgery, and "Listerism" has too firm a hold upon the professional mind to be injured by any such criticisms as I have ventured to make upon the facts which its distinguished originator has given to us, for our instruction, as crucial tests of his treatment.

In conclusion, Sir, allow me to repeat that I claim to be an antiseptic surgeon in its true sense as much as Mr. Lister, although I may not adopt Listerism as a rule of practice; and I ask again if Mr. Lister or any of his disciples admit that any antiseptic surgery exists outside the spray system? I ask you, Sir, to give an early and prominent position to this disclaimer.

I am,

Yours faithfully,

THOMAS BRYANT.

MEDICAL EDUCATION FROM THE STUDENT'S STANDPOINT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reference to an article published in your last number on "Medical Education," I would beg to say a few words in defence of a class of medical students who have been grossly and unjustly maligned.

With respect to the reception of "boys of undefined age," I might say that the curricula of all colleges (as far as I am aware) require at *final* examination proof of being at least 21 years of age. Then why concern ourselves at what age he commences his studies?

With the four following statements in the article I have nothing to do; they might refer to a class of students that I or any of my similarly-situated brethren would be ashamed to have anything to do with. They undoubtedly refer to that class that make up the "sundry manipulative procedures usually adopted for the treatment of the sick" in the grind-room during their final six months of study, and pay the usual (but exorbitant) sum of fees for certificates and diplomas to which they otherwise, than in a business point of view, have very little right!

But, Sir, the part which particularly interests me, and has moved me to trespass on your valuable space, is that referring to those gentlemen taking service "behind an apothecary's counter." With reference to them it is stated, in common with other behind-counters and clerks, that they are engaged at this business all day, while lectures and clinical instruction are going on. Now, Sir, if the author of that article had gone to the trouble (as he ought to have done) of making a few inquiries relative to apothecary-assistants, he would have found that they have two or three hours every morning for hospital attendance and lectures, in addition to evening hours for dissecting. Of course it would be scarcely necessary for me to point out many of the greatest men in the profession who in their student days held the position of "compounder."

It is also stated that pecuniary motives urge the "needy student" to undertake the last-mentioned occupation. Here, again, gross ignorance is displayed. How I ask, could a student pay for hospital, dissections, lectures, and clothe himself on £1, or at most £2 per month!!? Could he not get four times that in a commercial office, and thereby qualify sooner if his motives for accepting the post were only pecuniary? I firmly believe that in the breast of most apothecary-assistants there is another motive of far more import to the profession than that of scraping together a few pounds. I believe *the* motive to be—in order to obtain a *thorough* knowledge of "pharmacy" and "materia medica," *which can be obtained nowhere else.* Surely every compounder is familiar with some dozens of errors made *"by the head men of the day"* in writing prescriptions, which would not have occurred had the prescriber known anything of the properties and nature of the substance he was prescribing.

In conclusion, Sir, may I ask one question? Which is the better man—the one who spends his time in pleasure, and at end of allotted period pays his handful of money for his certificate and letters testimonial, and is at once transformed into a physician and surgeon; or the man who takes service behind an "apothecary's counter," or any other honourable employment, works himself up honestly and diligently from the lowest round of the ladder with anything but a full purse?

I hope, Sir, that you, in your capacity of Editor of a widely-circulated medical paper, will, by giving insertion to this letter, help the weaker members of the profession, and not allow them to be sneered at by those whose only qualification to do so seems to be a heavy purse.

I am, &c.,

ÆSCULAPIUS ROSA.

[1. As regards the age at which a student may qualify, our correspondent is in error. The attainment of 21 years is not, even in theory, enforced by all licensing bodies, and some of those who set it down amongst their requirements do not insist upon proper evidence of age. Moreover, we hold that it is much more important to prevent boys commencing medical study before either their mind, body, or education are fit for it than to prevent young men entering practice before the age of 21.

2. Our correspondent misunderstands us. We have never said that students are, as a rule, such as those referred to in his third paragraph. On the contrary, we have been careful to point out that our charge is against, not the student, but against the system, which leaves it altogether to his own inclination whether he shall idle or work, and which muddles his studies together in such a way that they are made unnecessarily difficult for him. We know that many students work thoroughly well, but we assert that they do so not in compliance with medico-educational regulations, but in defiance of them; and that if they did comply strictly they could not learn their business as well as they do.

3. We hold to our opinion that many students accept service in an apothecary's shop in order to save the expense of living in lodgings, and we believe that the "time allowed for lectures" is often imaginary. Nor do we admit that the "two or three hours" in the morning for hospital, and the "evening hours" for dissection are anything but a sham, for we are quite well aware that the student will be allowed these hours only when there is no business in the shop; that he, having been shut up all day behind the counter, is wont to cut short the hospital and the dissection in favour of a little necessary recreation, and that, even if he rigidly devoted the time which he is allowed—in theory—for these purposes he must necessarily omit the greater part of his studies. At once we declare that the whole day, and every working day for three years, is the very least sufficient period for learning to be a competent practitioner, though a couple of hours a day, and three months in a grind-room, may be enough to make the student a licentiate, and we utterly protest against any system which affords facilities for young men to occupy public or commercial positions, and to shuffle into the profession upon a disreputable pretence of medical study. As to the advantage of the study of practical pharmacy, we hold that with that handmaid to medical practice neither physicians nor surgeons ought to have anything to do, any more than a portrait painter has to do with the manufacture of his paints or his canvas. But we know that the general practitioner system in England, and the Poor-law medical system in Ireland, make a knowledge of dispensing necessary, and we, therefore, highly approve of that knowledge being acquired in an apothecary's shop, and we are far from depreciating the

Digitized by Google

status of students who so acquire it. We don't, however, regard it as "medical study," and we therefore look upon the substitution of a year's such work for a year's hospital and dissecting-room work—which is permitted in England—as only a means of evading one of the theoretic four years of study.—ED. M. P. & C.]

WOOL-SORTERS' DISEASE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I send by this post copies of the *Bradford Observer* of Dec. 4th and 11th, containing leaders, paragraphs, and letters on "Wool-sorters' Disease." It is not uncommon in Halifax from the sorting of camel's-hair. I have returns of several deaths. I have found the bacillus anthracis in the blood of animals inoculated with the blood of persons suffering from this disease. Previously I thought it a septicæmia. It differs, however, very much from anthrax or charbon, as described by Sanderson and in Ziemssen; I may call it pulmonary anthrax. I have tried for over two years to impress upon employers the necessity of washing or steaming dangerous wools before they are sorted. This will *certainly* prevent the disease. They will not do this unless compelled. Several coroners' inquests have recently been held on victims, and in consequence some firms have done something towards what is necessary, but not sufficient. I may mention a fact, recently under my own observation of three men out of nine, working in one room, who died from this disease within about a month of each other.

The mortality from disease of lungs (excluding phthisis), 13th Regist. Dist. 1851-60 of males aged 20 years and upwards, was 17·4 per cent. of the total mortality. In the Shipley sub-district, including Saltaire—where alpaca and mohair are largely used—the proportion for five years, 1872-6, was 68·2 per cent. What is to be done to compel employers to adopt the simple means necessary to prevent these frequently-recurring deaths? It appears to me that an inquiry by the Medical Department of the Local Government Board and the expression of public opinion through the press are most important, and if you contribute towards this through the columns of the *Medical Press* you would much oblige

Yours very truly,

W. H. BELL, M.D.

Bradford, Dec. 13th, 1879.

[In the *Medical Press and Circular*, April 10th and Nov. 13th, 1878, will be found articles on "Wool-sorters' Disease." We have already pointed out the necessity for legislative action to check this disease. We then emphatically expressed our opinion as to the possibility of stamping it out in the following words:—"It is, or should be, a preventible disease, and we are not saying too much in affirming that it ought to be stamped out from our vocabulary and become a memory of the past. We think the time has fully come for a scientific report on the disease." We are indebted to Dr. Bell for drawing our attention to the subject again, and for papers sent, and shall endeavour to comply with his wishes, particularly as we know that he possesses a rich experience on this sad affliction, and that he writes with almost the authority of an expert.—ED.]

Novelties.

LE DR. OLLIER'S MECHANICAL SAW.

ACCORDING to the *Journal de Medecine et de Chirurgie*, Nov., 1879, we learn that M. Ollier has introduced a new instrument for the purpose of resection, consisting of a small circular saw, which is set in motion by the revolutions of a wheel, to which it is attached by an india-rubber band.

It has been constructed for him by the well-known instrument maker, Collin, and M. Ollier has used it for a year with excellent results. Such a machine would only be useful in a large hospital, whilst at the same time it might be attended by serious mishaps arising either from some movement of the patient or misdirection of the surgeon. It is, however, curious, as an illustration of the mechanical direction which surgical instruments are taking, and might possibly lead to the construction of an instrument more compact and less liable to risk.

In dentistry, the introduction of the American drill, worked by the foot, has been found successful by many practical dental surgeons, and we have reason to believe that it would be easier to construct an instrument on the same principle which might be applicable in many important operations, especially for resection and excision, and which we consider would be far superior to the invention of M. Ollier, as it would not require an assistant to furnish the driving power.

BISHOP'S GRANULAR EFFERVESCENT CITRATE OF CAFFEINE.

WE have made trial of this preparation in some cases of migraine, and we found that it was attended by the most marked results, and as this preparation is presented to us in such an agreeable form, we may expect it will be largely used, both as a sedative, anodyne, and diuretic, for it has all these properties. Its beneficial action in migraine may be explained on the theory of M. Herz, that it is an arterial neurosis dependent on the great sympathetic nerves. It may also be found useful in all diseases associated with asthenia, such as melancholia, over brain-work, sleeplessness and depression of spirits from alcohol, and where a mild excitement is required to induce a proper state of nutrition.

BISHOP'S GRANULAR EFFERVESCENT EXTRACT OF NUX VOMICA.

NUX vomica is not as largely used as it deserves to be, and we gladly welcome a preparation which affords us the means of prescribing it in an agreeable and accurate form. In Bishop's granular form the bitterness of the preparation is considerably masked, and as each drachm contains 1-12th of a grain, to be taken in a third of a tumblerful of water, we are able to proportion the dose. A very useful little measure is supplied with each bottle, so that patients can measure with accuracy the dose. Messrs. Burroughs and Co., of 8 Snow Hill, London, are the agents for these preparations of Bishop and Company.

CONCENTRATED MINERAL WATERS.

MR. CONDY, well known as the manufacturer of the celebrated fluid which bears his name, now introduces to our notice a system of concentrating and oxygenating mineral waters, by which any known mineral water can be produced at pleasure. He takes any given water, as Vichy or Friedrichshall, extracts from them in concentrated form their medicinal qualities, charges them with nascent oxygen, then bottles them in their reduced bulk, so that a person may carry the constituents of a case of mineral waters with him in his pocket. With a teaspoonful of concentrated Vichy and a tumbler of soda water the inventor guarantees a draught of pure Vichy water. Certainly the idea is a most ingenious one, and if found to answer all that is said for it, the difficulty of transport of a favourite water when travelling will be materially diminished.

EUCHLORINE.

DR. ARCHER FARR, Medical Officer of Health for Lambeth, is responsible for this disinfectant. Various preparations and combinations of chlorine with other substances have been manufactured from time to time, but mostly with indifferent success when practically tested, whether "Euchlorine" will fare better, it is, as yet, hard to predict. We have not as yet interested ourselves

Digitized by Google

analytically, but upon applying the ordinary tests, it answered exceedingly well. It, moreover, possesses this novelty, that upon mixing equal parts of Nos. 1 and 2 effervescence takes place, and ozone and the oxides of chlorine are evolved; and by regulating the quantities it serves as an air purifier in the sick room or hospital ward, and is equally potent as a disinfectant when thrown down closets or drains after it has served its first purpose during effervescence. It has certainly a more agreeable odour than chlorine, and from its other excellent qualities should become one of our most popular disinfectants. The maker is Mr. White, Chemist, 332 Kennington Road, S.E.

Medical News.

Royal College of Physicians of London.—The following gentlemen were admitted Licentiates of this College on December 22nd:—

Adams, Alexander Peers; Greenholme, Kingston Hill.
Bates, Henry Leslie; Streatham Common, S.W.
Bond, Charles John; 80 Albert Street, N.W.
Branson, Cecil Lugard Smyth; 30 Tavistock Road, W.
Crew, William Thomas; 11 Falmouth Road, S.E.
Dimmock, Henry Peers; 13 Moore Street, S.W.
Ensor, Theodore Francis; Milborne Port.
Faulkner, Joseph; 36 Darnley Road, E.
Jones, Charles Montagu Handfield; 49 Green Street, W.
Lathbury, Charles John: Breaston, Derby.
Lewis, Christopher John; 16 Park Place Villas, W.
Lewis, George Stephens; Guy's Hospital, S.E.
Lovell, Robert Haynes; St. Mary's Hospital, W.
Mort, Herbert Brownlow; Southport.
Rich, Evelyn Arthur; Winchester.
Townsend, Knowlson; 18 Broughton Place, Edinburgh.
Warrburton, Arthur; Betley.

The following candidate, having passed in Medicine and Midwifery, will receive the College licence on obtaining a qualification in Surgery recognised by this College:—

McKee, Gerard Macklin Eccles; 2 Overstone Road, W.

University of Dublin.—At the Winter Commencements, held on Wednesday, December 17, the following degrees in Medicine and Surgery were conferred:—

Bachelor in Surgery.

Manning, George Henry
Beatty, Wallace
Williams, J. Almeric de Courcy
Pratt, Joseph Dallas
Johnston, Robert Henry

Bachelor in Medicine.

Manning, George Henry
Beatty, Wallace
Moore, Malcolm Henry
Sawyer, Richard Henry Stewart

Master in Obstetrics.—White, William Henry

Master in Surgery.—Wheeler, William Ireland.

Doctor in Medicine.

Hamilton, Thomas Kinley
Halpin, Nicholas John
Sharkey, Edmund
Fitzgerald, William Alexander
Flood, Stephen (*in absentia*)

The following honorary degree was also conferred:—

Doctor in Med. and Surg.—Reynolds, Jacob Henry (*honoris causa*).

King and Queen's College of Physicians in Ireland.—At the usual monthly examinations for the licences of the College, held on Monday, Tuesday, Wednesday, and Thursday, Dec. 8, 9, 10, and 11, the following were the successful candidates:—

For the licence to practise Medicine—

Barney, Richard Winter
Barry, Edward Frederick Sheehy
Berry, Edmund
Harding, James Joseph
Harris, Hugh
Hartt, Charles Henry
Henn, Edmund Poole Howell
Jackson, Thomas
Keelan, Michael
MacDonogh, Eliza Foster
O'Reilly, Francis John

For the licence to practise Midwifery—

Barney, Richard Winter
Barry, Edward Frederick Sheehy
Berry Edmund
Harding, James Joseph
Hartt, Charles Henry
Henn, Edmund Poole Howell
Jackson, Thomas
Keelan, Michael
MacDonogh, Eliza Foster
O'Reilly, Francis John

Up to and including December 12 the following Licentiates in Medicine of the College have been admitted to Membership in accordance with the provisions of the Supplemental Charter:—

Ashe, Isaac, Dundrum
Browne, H. P., Delgany
Chapman, John H., Dublin
Cormack, John Claude, Liverpool
Cox, Henry T., Portland
Craig, Richard M., A.M.D., Cyprus
Crespi, Alfred, Lundi Island
Dick, James N., R.N., London
Eames, Wm. James, Devonport
Foster, Balthazar W., Birmingham
Fuller, Joseph, Bristol
Hatchell Joseph H., Maryborough
Heard, R. L., Bray
Johnston, Andrew C., Aberlady
Jones, John Thomas, London
Keays, William, A.M.D., Cyprus
Kidd, Abraham, Ballymena
McVeagh, John Francis, Dublin
Madden, Thomas More, Dublin
Murdoch, Sidney, Dublin
Norman, Conolly, Monaghan
Oxley, Martin G. Black, Liverpool
Partridge, Thomas, Stroud
Patton, Alex., Finglass
Paul, Ernest Watson, Bridgwater
Peele, Edward, Dublin
Porter, Frank Thorpe, Dublin
Ross, Daniel McClure, Monaghan
Scott, R. R., A.M.D., Southampton
Scott, William, Aughnacloy
Styrap, Jukes de, Shrewsbury
Thomas, William, Sheffield
Thompson, James, Leamington
Walsh, John, Blackburn
Warren, Frederick W., Dublin
Williams, Thos., R.N., Dartmouth
Woodward, G. P. M., London
Worswick, Fred. H., Manchester

Army Medical Service.—The Director-General of the Army Medical Department presents his compliments to the Editor of the *Medical Press and Circular*, and will feel obliged if he will cause the enclosed list of the successful candidates at the recent competitive examination for Her Majesty's British Medical Service to be published in his columns:—

Names.	Marks.	Names.	Marks.
F. R. Barker	2,590	R. D. Donaldson ..	1,75
A. H. Keogh	2,525	H. L. E. White ..	1,745
C. B. Hill	2,420	C. M. Johnston ..	1,740
J. R. A. Clark	2,330	J. L. Hall	1,705
H. E. B. Flannagan ..	2,295	A. H. Burlton	1,700
H. J. Michael	2,280	E. North	1,695
T. Dorman	2,215	G. F. Poynder	1,693
A. W. G. Inman ..	2,185	J. K. Sherman Bigg ..	1,675
T. M. Corker	2,180	G. F. A. Smythe ..	1,665
E. H. Myles	2,145	H. L. Battersby ..	1,655
G. S. Robinson	2,125	A. Hewitt	1,645
F. B. Moffitt	2,115	E. Landon	1,640
C. A. Webb	2,075	G. Mulvaney	1,635
J. G. S Lewis	2,065	J. E. Nicholson	1,635
H. Martin	2,050	T. W. Beale	1,625
A. E. J. Croly	2,010	F. E. C. Hood	1,625
R. O. Cusack	2,010	W. O. Wolsley	1,610
E. F. Smith	2,010	T. F. McNeece	1,605
W. A. Cowen	2,000	R. V. Smith	1,590
R. H. Forman	1,995	B. T. McCreery ..	1,580
S. J. Flood	1,965	A. G. O'Connor ..	1,575
D. S. Williams	1,955	A. McM. Bolster ..	1,570
G. W. Robinson ..	1,940	D. Wardrop	1,545
N. Cameron	1,920	G. T. Goggin	1,520
J. Watson	1,910	H. G. Christian	1,485
O. Todd...	1,905	J. M. Jones	1,470
A. O. Geoghagan ..	1,876	F. M. Baker	1,465
C. R. Egan	1,810	C. Williamson	1,460
J. D. Day	1,805	R. Oliver	1,415
W. R. Henderson ..	1,805	A. Asbury	1,400
R. T. Cumming ..	1,800	J. M. Carleton	1,375
A. M. Kavanagh ..	1,795	F. R. Maclean	1,365
J. H. Harwood	1,765		

The following gentlemen having obtained the qualifying number of marks, have also been accepted:—

H. L. Cox
J. P. Carmody
R. W. Barnes
T. P. Walsh
G. H. K. McO'Callaghan
P. H. Fox
H. A. Wall

Harveian Society of London.—The annual general meeting of the Harveian Society will be held on January 8th, for the purpose of electing the officers and council for the ensuing year, and transacting the usual business. The following is a list of the names of gentlemen proposed by the Council as officers of the Society for the year 1880:—*President*—* Henry Power, Esq. *Vice-Presidents*—George Eastes, M.B.; Robert Farquharson, M.D.; * E. J. Gant, Esq.; * W. H. Day, M.D. *Treasurer*—* James E. Pollock, M.D. *Hon. Secretaries* J. Milner Fothergill, M.D.; George Field, Esq. *Council*—* Henry Chas. Stewart, Esq.; T. Fitzpatrick, M.D.; H. E. Sewill, Esq.; H. T. Mapleson, Esq.; Edmund Owen, Esq.; T. Buzzard, M.D.; * G. C. P. Murray, M.D.; * W. Squire, M.D.; * G. Danford Thomas, M.D.; * W. Ward Leadam, M.D.; * J. W. Langmore, M.D.; * Owen Roberts, Esq. An asterisk is prefixed to the names of those gentlemen who did not hold the same office the preceding year.

South London School of Pharmacy.—The Seventh Annual Dinner and Distribution of Prizes was held on Friday, last, December 19th, in the large hall at the Horns, Kennington, under the chairmanship of Dr. Muter, Principal of the School. About 140 sat down to dinner, the evening being diversified with music and theatricals, the prizes being distributed by Dr. Julius Pollock with his customary urbanity. The following is the list:—*Senior Chemistry*—

Digitized by Google

Medal, Mr. Eaton; Certificate, Mr. Harburn. *Botany*—Medal, Mr. Parkes; Certificates, Messrs. Banks and Grover. *Junior Chemistry*—Medal, Mr. Banks; Certificate, Mr. Littlefield. *Materia Medica*—Medal, Mr. Littlefield; Certificate, Mr. Slicer. *Pharmacy*—Medal, Mr. Webb; Certificates, Messrs. Fidler and Beech.

NOTICES TO CORRESPONDENTS.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

A GENERAL PRACTITIONER.—The leading consultants object to give advice in reply to country practitioners in the columns of medical journals; it is not unnatural that they should think that what is worth having is worth paying for.

A CANDIDATE FOR THE PASS.—With so many good text-books on surgery you cannot do wrong in taking either. The best and most modern are, Erichsen's, Gant's, and Bryant's.

ROYAL INSTITUTION.—On Saturday, Dec. 27, at 3 p.m., Professor Tyndall, "On Water and Air." (First Christmas Lecture.)

THE CINCHONA CURE FOR DRUNKENNESS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—As I find in the *Medical Press and Circular* of Nov. 26, p. 466, a quotation giving Dr. Hayne's opinion and experience regarding the "Cinchona Cure for Drunkenness," and as my experience in that matter is perhaps as much as Dr. Hayne's, and of a very different kind, I believe that, in fairness to a very important question, you will give publicity through your magazine to the purport, at least, of what I send you. No wonder that Dr. Hayne's experience was a failure, seeing he speaks of a case where a party took the remedy during the day, and then took strong drink at night. This is to violate an essential condition in the cure. This representative case is no case of trial at all, and it is to be feared that the other cases referred to by Dr. Hayne are of a like kind.

I send you a copy of the *Aberdeen Daily Free Press* containing an article I have marked, which article was written by the Editor as the result of his own personal investigation. Besides I could give you the names of many who are now entirely cured from the alcoholic appetite by the cinchona cure.

I am, most truly yours,

Deeside Hydropathic Establishment, near Aberdeen. ALEX STEWART, M.D.

ARMY MEDICAL SERVICE.—The next examination for admissions into the Army Medical Service will take place at the University of London on the 9th of February and following days.

E. H. C.—The prescriptions appear more than curious. We will take the opinion of one or two pharmaceutic authorities, and publish results in our next.

P. B.—We regret that we cannot depart from our rule of declining to advise patients in these columns.

A DISCLAIMER.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In publishing his "belief" that certain handwriting is mine, Mr. Smith (of the London Temperance Hospital) has pledged himself to "an inaccurate diagnosis," and has thus prepared for application to himself a charge of that "malicious defamation" which he seems anxious to fasten on others.

Whether or not you, Sir, have allowed a "defamatory letter" from me to appear in your columns, as alleged by Mr. Smith, and whether or not a reprint has been circulated in London, or elsewhere, are matters I need not argue with him. So far as I am concerned the question before the public is the *origin of the immersion paraboloid*; and I could only sustain my comments on Dr. Edmunds' claim in your columns by reopening the discussion—which you have closed. Those who are interested in the question may refer to the *English Mechanic* of Nov. 28th, the 12th inst., and the current number.

Yours, &c.,

224 Regent Street, Dec. 19, 1879. J. MAYALL, jun.

VACANCIES.

Belmullet Union, Bangor Dispensary.—Medical Officer. Salary, £100, with fees, and £10 as Medical Officer of Health. Election, Dec. 26.

Birmingham General Hospital.—Resident Surgical Officer. Salary, £120, with board. Applications to the House Governor before Dec. 29.

London Hospital Medical College.—Warden and Secretary. Emoluments amount to between £300 and £350. Applications to the Acting Secretary before Jan. 5.

Manchester, Hospital for Sick Children at Pendlebury.—A Senior and a Junior Resident Medical Officer. Salary, £100 and £30 respectively, with board. Applications to the Chairman of the Medical Board before Jan. 4.

Monaghan Union, Scots own Dispensary.—Medical Officer. Salary, £120, with fees, and £15 as Medical Officer of Health. Election, Dec. 30.

Oughterard Union, Lettermore Dispensary.—Medical Officer. Salary, £110, with fees, and £12 as Medical Officer of Health. Election, Dec. 31.

South Molton Union.—Medical Officer of Health. Salary, £130. Applications to the Clerk of the Guardians South Molton, before Jan. 9.

Sunderland Infirmary.—Physician. Honorary. Applications to the Secretary before Jan. 28.

Worcester General Infirmary.—Physician. Honorary. Applications to the Secretary before Jan 14.

APPOINTMENTS.

ADRIEN, E. W., M.R.C.S.E., Medical Officer to the Balrothery Union Workhouse.

ORR, J. W., L.R.C.P.Ed., M.R.C.S.E., Medical Officer for the Wollaston District of the Wellingborough Union, Northamptonshire.

SCOTT, J., M.B., C.M., an Honorary Surgeon to the Manchester Southern Hospital for Diseases of Women and Children.

SCOWCROFT, J. E., F.R.C.S.Ed., L.R.C.P.Ed., an Honorary Surgeon to the Bolton Infirmary.

STEVENSON, W. E., M.B., M.R.C.S.E., House Surgeon to the Hospital for Sick Children, Great Ormond Street.

WHARRY, A. J., M.R.C.S., House Surgeon to the Great Northern Hospital.

Births.

CROGHAN.—On Dec. 16, at 142 Capel Street, Dublin, the wife of Dr. E H. Croghan, of a son.

MERRICK.—On Dec. 1, the wife of Alex. Stewart Merrick, M.D., Resident Medical Superintendent Belfast Hospital for Insane, of a son.

TURNBULL.—On Dec. 8, at Kelso, N.B., the wife of G. H. Turnbull, M.D., of a son.

Marriages.

WILSON-NOLAN.—On Nov. 18, Thomas Wilson, M.R.C.S.Eng., of Edgewortstown, to Lizzie, daughter of A. Nolan, Esq., Nenagh, co. Tipperary.

HUNT—MILLER.—On Dec. 10, at St. Jude's, Mildmay Park, London, N., the Rev. J. J. Hunt, of Bolton, to Jessie, second daughter of C. M. Miller, M.D.

Deaths.

DAVIS.—On Dec. 11, at Waterloo Road, Dublin, John N. C. A. Davis, F.R.C.S.I., Deputy Inspector-General of Hospitals, Army Medical Department.

DUNLOP.—On Dec. 6, at Blacket Place, Edinburgh, John Dunlop, M.D., Deputy Inspector-General of Hospitals and Fleets.

GEORGE.—On Dec. 4, at Weston-super-Mare, Richard Francis George, M.R.C.S.E., aged 81.

MACDONALD.—On Dec. 7, at Lynedal House, Isle of Skye, John Macdonald, M.D., of Buenos Ayres.

MACLURE.—On Dec. 13, at Harley Street, Duncan Maclachlan Maclure, M.B.

O'CONNELL.—On Dec. 13, at Templemore, co. Tipperary, Daniel O'Connell, L.R.C.P.Ed., aged 38.

TULLOCH'S
PURE DUTCH COCOA,

Four times the Strength of Ordinary Cocoa.

Sold by all Grocers, Chemists, &c., in 1lb., ½lb., and ¼lb. Tins.

SAMPLES WILL BE SENT TO MEDICAL MEN ON APPLICATION.

WILLIAM TULLOCH & SON,

Cocoa and Chocolate Manufacturers,

BURY ST., E.C.

NOTES ON BENZOATE OF SODA IN A CASE OF GUMMATA OF THE SKIN (LUPUS SYPHILITICUS).

By J. B. BERKART, M.D.,

Senior Assistant Physician to the City of London Hospital for Diseases of the Chest, Victoria Park, &c.

ON the 19th of July, 1879, Mr. N. consulted me on account of a number of sores, which, within the last two years, had gradually developed themselves all over his body. He stated that he had taken for a considerable time large doses of mercury, and then of iodide of potassium, but had derived no benefit from the treatment; for scarcely was an ulcer formed in one place when one commenced to break out in another. He felt, moreover, very weak, he had lost his appetite, and was greatly depressed in mind.

Mr. N., æt. 38, is the father of three children, of whom the youngest is seven years old, but he has been a widower three years since. He did not remember having ever had a serious illness. He has had, fourteen years ago, gonorrhœa, from which, however, he had completely recovered in a few weeks. With the exception of occasional attacks of gastric derangements, he had always enjoyed good health until four years ago. At that time he had noticed, in the palm of his left hand, an eruption of red spots, which, on applying for advice, were considered as being of syphilitic origin. Although he freely admitted that he had exposed himself to the danger of a syphilitic infection, he was yet positive that he had never had a sore on the penis, nor enlarged lymphatic glands anywhere. After a course of mercurial fumigations the red spots had soon disappeared without leaving any traces. He had never had sore throat, disease of the skin, nor had he lost his hair. Two years ago he had accidentally noticed a small sore, which, without causing pain or inconvenience, had developed itself in front of the left leg, at about the middle of the tibia. He had at once submitted himself to anti-syphilitic treatment, but not only had that sore greatly increased in size, but others had shortly afterwards formed on various parts of his body. He had, in the course of time, lost flesh, and had a week ago a fainting fit while his wounds were being dressed.

Stat. Præs. Patient is of small stature, rather thin, and very anæmic. A number of ulcers situated at the point of junction of the hairy scalp with the forehead, on both parietal and the occipital bones, encircle the top of the head like a wreath, as it were. There are ulcers also on the top of the head, on mid-sternum, in the inter-scapular region, on the abdomen,—the greater portion of them on the left side; on the left side of the penis, and of the scrotum; on the left thigh, and on the right arm, and on the right calf. On the middle of the left tibia in front there is a larger dark brown cicatrix, about 3″ in transverse diameter. On the right forearm, in the middle of the radius, there is a dark red spot of the size of sixpence, surrounded by a dusky areola; it is slightly elevated over the surface, firm to the touch, painless, and adherent to the subjacent tissues. The rest of the skin seems healthy.

Most of the ulcers are of circular shape, with the exception of those where several have coalesced, and they look as if punched out of the skin; the edges are somewhat thickened, but there is no trace of inflammatory reaction around them. Their depth varies; some are quite superficial, others penetrate for almost ¼″ into the subcutaneous tissues. They are covered with a scanty greyish-white, very tenacious substance, which, when removed and examined by means of the microscope, appears to consist of large, homogeneous cells, strongly refracting light, without nucleus, and giving with methyl-violet the reaction of amyloid. There are nowhere enlarged glands to be felt. Temp. normal, and the patient states that he has never felt feverish. Pulse is small, very soft, 90. The muscles are thin and flabby; the thorax is well developed, cardiac impulse is neither seen nor felt, and the heart is apparently covered by the lungs. The percussion of the right side

Digitized by Google

of the thorax is dull in front from the second to the fourth rib. There is no respiratory murmur on the right side, and that on the left is very feeble. The sounds of the heart are clear but feeble; those of the aorta are markedly conducted outwards to the right axilla. The tongue is pale, large, and flabby. His bowels act daily, and there is nothing apparently abnormal in the abdomen.

The diagnosis of this case could not be doubtful. The rapid formation of the sores all over the body following the cutaneous eruption on the palm of the hand; the shape of the ulcers and their peculiar edges, and the absence of all inflammatory reaction around them; the scanty tenacious secretion; the state of the skin between the sores; all these signs make it highly probable that the case is one of gummata of the skin,—a true lupus syphiliticus. It has, of course, to be considered that the patient positively denied the existence of an initial sclerosis, and of enlargement of the lymphatic glands. But it is not impossible that the primary sore may have been slight and superficial, rapidly tending to recovery, as it frequently occurs, and without implicating the lymphatic glands. Possibly there may be also a constitutional proclivity to the formation of lupus,—a proclivity which the syphilitic infection may have roused into activity.

The question of treatment was very embarrassing. The patient had for a considerable time taken large doses of mercury, and also of iodide of potassium, without any benefit. His digestive organs were at the time so deranged that it was deemed advisable to discontinue for a while all active treatment, but to allow them to recover their functional energy. The question of subcutaneous injections of mercury was also considered; but apart from the objection of the patient to that treatment, it was thought that a short delay of all therapeutic interference may possibly show whether a sufficient amount of mercury had already been introduced into the system.

The patient was therefore ordered merely to apply iodoform to the ulcers.

July 26.—There was no improvement. The patient was still more depressed in spirit because the gumma on the right forearm, above mentioned, had broken down, and was now formed into a round ulcer. Not far from this a dark red spot appeared. His appetite was in no way improved, and his weakness had increased. It was therefore necessary now to do something. Considering the favourable results which Schüller has obtained in scrofulous ulcerations by means of benzoate of soda, it was thought that this drug might prove useful also in the present case. The patient was consequently ordered:—

℞ Sod. Benzoat., ʒss.;
T. Cardam. co., ʒss.;
Aq. Menth. Pp. ad ʒj.

M.S.—To be taken twice a day.

As he objected to the iodoform on account of its smell, water dressing was substituted for it. He was directed to take, as soon as his appetite was improved, two tablespoonfuls of cod-liver oil twice a day.

Three weeks later he again presented himself. His appetite was now considerably improved, and he felt much stronger. The more superficial sores had quite healed, and were, as in the penis and scrotum, covered with epidermis, while nothing but a slight induration indicated the seat of the previous disease. On the chest, the hands, and the abdomen the reparative process was equally active; the loss of substance was everywhere repaired, and epidermis began to form from periphery towards the centre. Only the sores around the head had made little progress towards recovery, but this delay could be accounted for by the local irritation, produced partly by scurf of the scalp, partly by ointments which the patient had used to avoid having a bandage around his head, and partly by his wearing an old felt hat soaked in perspiration. On the forehead, more especially, the sores looked angry and spreading. To avoid further mischief the head was ordered to be shaved and to be carefully washed, and the sores were protected by bandages against irritation. The benzoate of soda and cod-liver oil were continued as hitherto. In the course of fourteen days, cicatrisation appeared also on the forehead.

The improvement of this case was certainly more rapid than is usually attainable by means of mercurial and iodine preparations. I limit myself, however, for the present, to the statement of facts, but refrain from drawing far-reaching inferences. Perhaps, after a larger experience, it may be possible to decide whether benzoate of soda exerts a favourable influence on the protracted forms of constitutional syphilis.

ON BRONCHITIS.

By G. HARRISON YOUNGE, L.R.C.S.I., L.K.Q.C.P.I., &c.

Bronchitis is a disease than which there is none more frequent or more important. Its importance depends as well on its frequency as on the serious morbid changes which may remain behind, and on the number of deaths which it causes, especially in young children and old persons. It is therefore essential that we should be acquainted with the disease in its every detail, and be prepared to treat it in all its varieties.

Bronchitis usually results from exposure to cold, but it may arise from other causes. Thus we have mechanical bronchitis, resulting from the irritation of the mucous membrane, due to the constant inhalation of air rendered impure by the presence of particles of dust, iron, &c. Again, we have secondary bronchitis, occurring in fevers, gout, and Bright's disease, and depending on the vitiated state of the blood. Another important cause of bronchitis, and one which should always be borne in mind, is mitral regurgitation; in this case it is due to the constant state of congestion of the lungs. There are numerous classifications of bronchitis, but the most practical is into Acute and Chronic. Another important division is that based on the part of the bronchial mucous membrane affected, viz., ordinary bronchitis, where the mucous membrane of the large bronchial tubes is implicated; and capillary, where the disease is confined to that of the small tubes. Of course both of these forms frequently co-exist.

The symptoms of bronchitis are chilliness and coryza, followed by pyrexia. The temperature rises to 101° or 102°; the skin becomes hot and dry, the pulse rapid and full, the tongue is furred, there is thirst and loss of appetite, the urine becomes diminished in quantity, high in colour, and deposits lithates; the bowels are constipated; there is cough, at first frequent, preceded by an unpleasant sense of tickling in the throat; it sometimes comes on in paroxysms, and is especially troublesome at night. There is a feeling of post-sternal oppression, and of soreness and tenderness at the lower part of the sternum, caused by constant coughing. At the commencement of the attack the secretion of the mucous membrane is diminished; soon a clear, viscid, frothy mucus is expectorated; after some days the expectoration becomes thick, muco-purulent, and only partially aerated. The physical signs are quite distinctive in uncomplicated cases. Bronchitis is bilateral; percussion is normal. At the commencement of the attack sonorous rhonchi are heard on auscultation over the larger tubes, while over the borders and apices of the lungs vesicular breathing is heard as usual. These morbid sounds are caused by the air entering tubes whose calibre is lessened by the swollen and dry state of the mucous membrane. When the bronchial secretion becomes profuse, large bubbling râles take the place of the dry sounds.

Capillary bronchitis, or suffocative catarrh, is a highly dangerous affection. It is much more fatal when it attacks, as it usually does, young children, or persons who are past middle age. The attack may be primary, or it may supervene on an ordinary case of bronchitis. The symptoms are very severe, and are generally quite characteristic. The attack is ushered in with the usual febrile symptoms; soon, however, urgent dyspnœa, with

Digitized by Google

occasional paroxysms of orthopnœa, sets in; cough becomes violent and paroxysmal, expectoration is very difficult, owing to the very viscid nature of the sputa, the circulation through the lungs becomes greatly embarrassed, the right side of the heart is engorged, the jugular veins are distended, the face assumes a dusky hue, and the lips are livid. If the case proceeds to a fatal termination the face becomes covered with cold sweat, the surface begins to cool, the pulse becomes weak and irregular, the expired air is cold. The patient becomes comatose, and in some cases dies convulsed from the action of carbonic acid on the brain. The physical signs are the same as in the former variety, except that in this case fine bubbling râles are heard instead of the large ones.

Chronic bronchitis usually follows the acute. In old persons, however, it comes on every winter, when it is known by the name of winter cough. It is this winter cough which is the great cause of emphysema; it should, therefore, be looked upon as a most serious affection, and should receive prompt and careful treatment. The symptoms and physical signs of chronic bronchitis are the same as in the acute. The diagnosis of uncomplicated bronchitis presents no difficulty. In some cases, however, where complications occur, it may not be easy to determine the exact nature of the disease. Thus, there may be dulness on percussion; this is due to the mucous membrane having lost its usual sensibility. The patient is, therefore, not aware of the necessity for coughing. The accumulated secretions gradually gravitate to the base of lungs and produce the dulness. This dulness has not infrequently been mistaken for pneumonia. It may, however, be readily recognised by the absence of the characteristic symptoms of pneumonia, such as the prolonged rigor, the rapid rise of temperature, the pungent burning skin, the great disturbance of pulse-respiration ratio, &c. On physical examination the dulness in bronchitis will be found to occupy the most dependent part of the lung, not, as in pneumonia, mapping out a lobe. The dulness will also change with change of posture, while vocal fremitus and resonance are diminished.

Chronic bronchitis with dilated bronchi may be mistaken for phthisis. Dilatation of a bronchus may be caused either by collapse of a lobule of the lung, the bronchus then dilating to fill the vacuum thus formed, or from long continued and difficult cough, the bronchus giving way at some weakened point. These cases resemble phthisis in the following points—emaciation, sweating, debility, cough, expectoration. It may usually be diagnosed from phthisis by the fact that phthisis begins at the apex; dilatation generally takes place at the root of the lung, in the vicinity of the large bronchi. In phthisis there is hæmoptysis; in dilated bronchi thisis absent. The sputa are fœtid in dilated bronchi, they are not in phthisis. Attention to the above points, together with careful physical examination, will generally be sufficient to clear up the case. If not, the progress of the case will remove all doubt.

In speaking of the morbid anatomy it is necessary to know that bronchitis may prove fatal and yet no marks of inflammation appear on the mucous membrane. This, however, can only occur when the smaller tubes alone are affected. It is due to the fact that the mucous membrane of the capillary tubes approaches in character a serous membrane, and serous inflammations frequently disappear after death. In ordinary cases the mucous membrane is covered with thick tenacious mucus. When this is removed the membrane underneath is found thickened, red, and irregular. In some cases even slight ulceration of the mucous membrane may be seen.

Plastic bronchitis deserves mention here, as, though not often met with, it may be mistaken, when it does occur, for phthisis or pneumonia. Its symptoms are wasting, cough, hæmoptysis, and expectoration of plastic casts, called bronchial polypi, and dulness on percussion. It may be diagnosed from both phthisis and pneumonia by the fact that plastic casts of the bronchial tubes are expectorated, and on physical examination vocal fremitus and resonance are diminished instead of increased.

Syphilitic bronchitis is an affection deserving of careful consideration from the fact that it is liable to be mistaken for phthisis, and which, if not properly treated, will assuredly become phthisis. The symptoms resemble those of phthisis in the following points. There is great emaciation. In the syphilitic affection, however, the patient has a peculiar dull, cachectic appearance, which is very suggestive of syphilis. There are night sweats, but in this case the cutaneous exhalation is clammy, and has a heavy unpleasant smell. Hæmoptysis is a marked symptom, but the expectorated blood, instead of being of a bright arterial hue, is dark in colour, and somewhat grumous. Diarrhœa is a very troublesome and persistent symptom, which usually defies all ordinary treatment. There is dulness on percussion, but instead of being at the apex, as in phthisis, it occurs in scattered patches over both lungs, being due to gummatous deposits. Cough is not usually so troublesome a symptom as in phthisis. Expectoration is usually profuse, and the expectorated matter is fœtid.

From the above we see that the following are the chief points of distinction between these affections:—

1. In syphilitic bronchitis the sweat is clammy and unpleasant in odour; in phthisis it is not.
2. In syphilitic bronchitis the expectorated blood is dark and clotted, in phthisis it is bright in colour.
3. In phthisis the dulness is apical, while in the bronchitis it occurs in scattered patches.
4. The expectoration is fœtid in syphilitic bronchitis, it is not in phthisis.
5. In phthisis the patient is bright and hopeful, while in syphilitic bronchitis the expression is dull, heavy, and depressed.

The morbid appearances distinctive of syphilitic bronchitis are the presence of gummata in the substance of the lungs. These growths are situated in the connective tissue between the air vesicles and bronchial tubes. They are surrounded by a layer of connective tissue, which contains a number of blood vessels; inside this is a covering of fibrous tissue; the centre of the tumour is filled with a dirty yellowish-grey substance, which after a time undergoes caseation.

It is now necessary to consider shortly the most important sequelæ of bronchitis. Of these, that which first claims attention is phthisis. Frequently repeated attacks of bronchitis may produce phthisis in subjects in whom not the slightest hereditary tendency exists. If such is the case how much more likely is phthisis to result in persons who are already predisposed to the affection. In patients who are phthisical bronchitis works the greatest havoc, so that in these cases it is of the greatest importance to treat the slightest attack at once, and continue the treatment until the disease is thoroughly cured.

Another very important sequella of bronchitis is emphysema. It most frequently occurs in old persons who have suffered for some time from winter cough; yet no age is exempt from it, and it may even be met with in young children where strong family predisposition to fibroid degeneration exists.

Emphysema may be caused either by collapse of a lobule of the lung, when the surrounding vesicular portion becomes emphysematous to fill the space formerly occupied by the collapsed lobule. This, however, is of comparatively little importance. Or the whole or greater part of the lungs may become affected. In these cases it is caused by frequent cough, especially where any obstruction exists to the free expiration of the air. When such is the case, the air is forced into the air vesicles, which distend and burst. After a time the lungs permanently lose their elasticity. When this takes place a disease becomes established, which causes the greatest possible inconvenience to the patient, and which exerts a most detrimental influence on his general health.

In the treatment of bronchitis the indiscriminate use of expectorant medicines frequently does much harm. Thus

Digitized by Google

I have several times seen cases where the mucous membrane was dry, inflamed, and irritable, yet in these cases turpentine was ordered, which being a powerful styptic, as we know, could only aggravate matters. Yet, if the prescribers are asked why they use turpentine in these cases, their invariable answer is, "Because it is an expectorant"! Such treatment is manifestly incorrect and unscientific, for expectorants have their special modes of action as well as any other class of medicines. If we consider these special modes of action we find that tartar emetic and ipecacuanha increase the secretion from the mucous membrane. Alkalies, especially ammonia, increase the amount of, and at the same time liquefy the mucus, thus assisting its expectoration. Blue pill increases the secretion, and also acts as a powerful alterative. It is very useful when combined with ipecacuanha.

The medicines which facilitate expectoration are carbonate of ammonia, senega, squill, and stimulants. Turpentine diminishes the secretion, but from its stimulant action it also assists expectoration; it is therefore specially indicated in debilitated patients in whom there is profuse expectoration.

Opium, morphia, and hydrocyanic acid relieve cough, but they should only be given where they are really necessary, as they diminish the secretions.

When a person is seen suffering from the premonitory symptoms of bronchitis, the attack may sometimes be cut short by a hot mustard bath and ten grains of Dover's powder at bed-time. I have often seen this treatment successful in what threatened to be a very severe attack of bronchitis. If, however, this does not succeed in checking the disease, the patient should be confined to the house, or if the attack is bad to bed. The temperature of the room should be kept at about 65 deg.; it should be well ventilated, but the patient must be carefully preserved from all draughts. The action of the skin should be promoted either by vapour or camphor baths.(*a*) If the bowels are irregular 5 gr. of calomel, followed, if necessary, by a dose of castor oil in the morning, acts better than any other aperient. In bronchitis, occurring in strong adults, I prefer tartar emetic, in one-sixth gr. doses, to any other remedy; it frees both the bronchial and cutaneous secretions, and lessens the inflammation. It may very advantageously be combined with spt. ammon. arom. Tincture of aconite in 2 m. doses every hour is very useful, especially in phthisical persons, where the great object is to overcome the inflammation in the shortest time possible; it should, however, be used with caution. Leeches to the chest and dry cupping afford great relief. Linseed meal and mustard poultices should be kept frequently applied.

In capillary bronchitis tartar emetic may be given for the first day or two, but if there are any signs of depression it should be omitted. Afterwards spirits of turpentine with ammonia and ether are the most useful remedies. Ether is here very valuable, as, besides being a diffusible stimulant, it overcomes any spasm of the muscular tissue of the bronchial tubes which may exist. If the kidneys are not acting properly spirits of juniper may be given with great advantage. Stimulants are generally required, and the diet should be nutritious and easily digested. Turpentine stupes and linseed and mustard poultices should be kept constantly applied. In those cases where the bronchial tubes become blocked up with mucus, an emetic will bring this away, and afford great relief. When the acute symptoms are passing off iodide of potassium and carbonate of ammonia internally, with flying blisters about the sternum, afford the best results.

In chronic bronchitis it is of great importance to improve the general health. The diet must be carefully regulated; stimulants are needed in most cases; and a general tonic plan of treatment should be adopted. The condition of the bowels should be inquired into, and if necessary corrected. If the heart is affected tincture of digitalis should be given. Where there is bronchorrhœa, turpentine, chloride of ammonium, and the balsams, together with inhalations of turpentine, creosote, or iodine, are most effectual in relieving excessive secretion. If there are fœtid sputa carbolic acid inhalations will usually correct this unpleasant symptom. When the healthy action of the mucous membrane is becoming re-established arsenic is very beneficial; it increases the appetite, improves the state of the blood, and restores the tone of the pulmonary tissues. If there is anæmia tincture of the perchloride of iron may be combined with the arsenic; if this is done the bowels should be kept regularly acting, or the iron will have little effect. Iodide of ammonium and sulphur are most useful in gouty bronchitis.

Persons who suffer from winter cough should, if possible, reside during that season in some mild climate. If this cannot be they should be kept constantly under observation, and the slightest pulmonary symptoms should receive attention and treatment.

In syphilitic bronchitis mercury should on no account be given, or the case will become one of phthisis. Iodide of potassium and iodide of iron, with decoction of cinchona, will generally greatly relieve the symptoms. Cod-liver oil with good diet will assist in restoring the patient.

(*a*) To give a camphor bath the patient is undressed and placed on a cane-bottomed chair, being then surrounded by a cloak. About one drachm of camphor is placed in a crucible and burned under the chair; after remaining for a few minutes in the vapour the patient is removed to bed, in a short time a gentle perspiration sets in, which is most beneficial. The bath may be repeated every second day.

Clinical Records.

PUERPERAL ECLAMPSIA BEFORE LABOUR—RECOVERY.—THE VALUE OF CHLORAL AND CHLOROFORM.

Under the care of Dr. GRELLOT,

With remarks by Dr. J. LUCAS CHAMPIONNIERE, (*a*) Chirurgien des Hopitaux de Paris.

MME. H., æt. 28, a woman of nervous temperament, had been married some years; about two years previously had a false conception, without any consecutive complication. I was called to her 30th September last, when she presented all the appearances of puerperal eclampsia, the result probably of a fright from having seen a woman die, a month previously, in an epileptic attack. The paroxysms came on very frequently. On vaginal examination I found the neck of the uterus undilated. I prescribed a potion of six grammes of bromide of potassium to be taken, in two draughts, at a quarter of an hour's interval. The first was returned, the second retained, though this had not much effect on the symptoms. On my second visit the pulse was 130, temperature very high, unconscious. I could not expedite delivery, nor could I bleed, so the following lavement was prescribed:—

Hydrate of chloral, 5 grammes; (*b*)
Distilled water, 250 grammes;
Yolk of egg, 1 gramme.

This injection was absorbed. The attacks ceased, the uterine neck dilated, and in twenty-four hours delivery took place naturally. The child, though small, was living, and mother and child have since done well.

Remarks.—In reference to the preceding observation, we may recall to the minds of our readers the present position of the treatment of eclampsia by chloral. A very remarkable memoir of Dr. Testut, *couronné* by the Academy of 1877, exhausts the question, and if we admit his conclusions, chloral is *the* treatment for this condition. It consists in introducing into the economy in the most speedy manner 4 to 10 grammes, commencing with 4 grammes, and administering it progressively in one-gramme doses. It is certain that it is an excellent

(*a*) *Journal de Med. et de Chirurg.*, Nov., 1879.

(*b*) By consulting our Metric Tables the reader will be able at once to convert the French measures into English equivalents.

Digitized by Google

medicine. According to Dr. Testut the stomach should be avoided, as a means of introduction, owing to the danger of injuring the mucous coat. The subcutaneous method presents dangers owing to the eschars resulting. The rectal method should be usually adopted, and he prescribes :—

Hydrate of chloral, 10 grammes ;
Distilled water, 100 grammes.

The first injection consists of 4 grammes of the above. Its effects are watched, and if necessary the injection is repeated every hour, of the strength of one gramme, until the eclamptic symptoms cease, and the patient has fallen into a profound state of anæsthesia. She must be incessantly watched, so that on a return of the symptoms fresh measures may be adopted.

If the rectal way is impracticable the arm must be chosen, and a solution of chloral in distilled water, neutralised by a solution of some drops of carbonate of soda, be subcutaneously injected.

I admire the high value of chloral, and there are cases where it acts in a marvellous manner. I have seen a woman in whom, after three most violent attacks, two grammes of chloral definitely suppressed the eclampsia. As a rule a much larger dose is required. I have seen chloral fail completely. Without, then, detracting from the usefulness of chloral in certain cases, I shall speak of the treatment which I recommend. I believe especially in the efficacy of anæsthesia, combined with general bleeding, if there are symptoms of congestion. I may say I have never seen a woman die who has undergone this treatment regularly and correctly, shortly after the *debut* of the symptoms of eclampsia.

Anæsthesia is easy, but it should be sustained, and chloroform administered anew, as soon as there is the least symptom of a return of the attack. Neither should she be left ; she should neither be touched, irritated, or tormented in any way. When the face is very congested, before anæsthetising I draw off four to five hundred grammes of blood, according to the strength of the patient ; and if during the process of anæsthesia the congestion is pronounced, I interrupt it in order to bleed. I must condemn the practice of leaving the patient as soon as she has been some time without an attack. We need not fear to give large quantities of chloroform. I have myself administered from 280 to 300 grammes. Chloral is an excellent medicine, but chloroform has a more powerful action on the paroxysms.

AN ANALYSIS OF RECENT ADDITIONS TO OPHTHALMOLOGICAL LITERATURE.

By ARCHIBALD H. JACOB, M.D., F.R.C.S.I.

THE last half of the year 1879 may be marked in the professional calendar as especially prolific of ophthalmological and aural literature, and amongst the books published within that period—many of which are, as is usual, ephemeral productions, written to obtain a practice and a name—we find some sterling works which indicate the scientific activity of the professors of these specialities, and which present to us the outcome of much thought upon this branch of surgery ; albeit nothing very novel or very srtiking is recorded which may mark this epoch in the annals of ophthalmology and otology. The first book before us is the translation by Dr. Burnett, of Washington, from M. Landolt's lectures on the methods of examination of the eyes. (*a*)

The author's high character as a scientific ophthalmologists and especially as a *savant* in regard to anomalies of the accommodative function, gives weight and interest to his lectures, and afford a sufficient reason for their republication in English by Dr. Burnett. M. Landolt has done much towards perfecting and promulgating the dioptric system of mensuration of the optical conditions of the eye, and upon this part of his subject, at least, his views may be accepted as most reliable. Dr. Burnett introduces the lectures to his readers with the statement that his reprint of them "is not a mere translation of the French editions of Landolt's 'Diagnostique des Maladies des Yeux' and 'Manuel d'Ophthalmoskopie,' but that both the original and the translation have been carefully revised by the author and so much new matter has been added that Dr. Burnett's rendering of the lectures is in many important particulars a new book.

The author announces in his introduction that "he intends to leave to physiologists the task of working out those problems which are purely scientific, and only occupies himself with those which are indispensable to our daily practice." We must therefore be content to regard these ectures as made for practitioners, and to look behind them and before them for the results of Dr. Landolt's actual scientific works. In the first chapter we find well-deserved care given to the objective examination of the patient, his cranial and facial peculiarities and their value as an indication of anomalous states of the eye. We have not seen this subject so well dealt with in any work, and the chapter will repay perusal even by the experienced ophthalmologist. Speaking of the necessity for careful examination of the everted lid and of the retro-tarsal fold, the author says : "It is astonishing what we sometimes find hidden away under the upper lid. It is not only the seat by preference of granulations, but also of foreign bodies of all kinds. A grain of sand, a bit of coal, &c., nearly always seek refuge here. Would you believe that I have found in three different cases eye-stones which the patients had introduced under the upper lid in order to drive out a grain of sand ?"—to which the translator adds that it is the custom in some portions of the United States to introduce "for this purpose, a flax seed into the eye." We have ourselves seen a case in which a grain of oats had remained for several weeks in the same position, while the patient was leeched, blistered, and purged for the cure of all sorts of imaginary diseases.

In this chapter the author dwells upon the importance of observing the distance between the two eyes, and insists that abnormality in this part of the facial contour is the chief cause of insufficiency of the internal rectus. For the purpose of measuring the amount of this anomaly he—having recapitulated the disadvantages and uncertainties of the ordinary methods—proposes the use of an apparatus invented by himself, which he names a "chiasmometer." It seems deserving of being illustrated and described in the author's own words :—

"It is a box (Fig. 1) having the form of a rectangle, of sufficient length, one end of which has two holes (*o o'*) for the eyes and a depression for receiving the nose.

"Each of the two openings is provided with a short tube in which to place the eye, and they can be separately closed by a movable slide from the inside.

"A vertical plate divides the box into two parts ; it is situated exactly in the middle of the distance separating the further extremity of the box and the line uniting the centres of rotation of the eyes.

"The further extremity of the box is closed by two plates, which can be moved separately in a lateral direction. In each of these is a vertical slit (*i'* and *i*). A similar slit

Landolt, Director of the Ophthalmological Laboratory at the Sorbonne, Paris ; translated by Swan M. Burnett, M.D., Lecturer on Ophthalmology and Otology in the Medical Department of the University of Georgetown, and Ophthalmic Surgeon to the Central Dispensary, Washington. Authorised translation, revised and enlarged by the Author. London : Baillière, Tindall, & Cox. Philadelphia : D. G. Brinton, South Seventh Street. Royal 8vo., pp. 307.

Digitized by Google

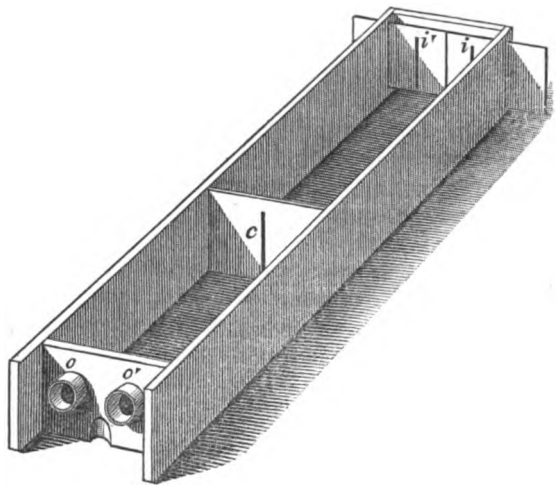
(*c*) is made in the middle of the central diaphragm. A cover encloses the whole.

"To measure the distance between the two eyes we apply them to the anterior extremity of the box, each one looking through its appropriate opening. By means of the slide on the interior one of the openings, for example, the one corresponding to the left eye, is closed, and the right eye alone looks into the box. This eye can see nothing so long as the slit in the middle and the slit on the left at the other end do not correspond with the visual axis of that eye. We can bring this about, however, by a suitable movement of the left movable plate at the further end of the box.

"We proceed in a similar manner with the other eye.

"You can easily understand that the distance (*i' i*) between the two movable slits so placed will represent the distance (*o o'*) which separates the two eyes, since the distances are bases of two equal triangles.

FIG. 1.



"It is easy, however, by using the same principles, to arrive at the same result in another manner. Take, for instance, a rectangular plate with a needle fixed in its centre, and at one of its extremities two movable needles; the eyes placed at the other extremity sight, one after the other, by the central fixed needle, at the needles beyond, moving the latter until they are covered by the central one.

"Thinking that it is easier for our patients to mark definitely the moment when they perceive a light, I usually employ the first form of apparatus. To this apparatus I have given the name of *chiasmometer*, because it is based upon the crossing of the visual lines.

"To obtain greater exactness in this method we can place in the central slit a fine thread or hair, which should appear exactly in the centre of the illuminated space when the central slit coincides with one of the slits at the further end.

"The great advantage of this method is that it requires neither a parallelism of the two eyes nor a simultaneous fixing of the same point. This enables it to be applied even to strabismic eyes, and to cases where there is an insufficiency of the muscles."

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

DR. KEELING communicated the particulars of

TWO CASES OF EXTRA-UTERINE FŒTATION.

CASE I.—M. W., æt. 28, married, was admitted into the Jessop Hospital on May 28, 1876. A slight, but fairly healthy woman, married for four years, but without family. From the very confused and uncertain account given, the following particulars as to her uterine history were gleaned. Menstruation had always been abundant, but regular, and with usual interspace of time until spring of 1878, when she had an excessive discharge, and was thought to have aborted. After this, and for a period of about five months, there was a constant sanguineous discharge from the uterus, not materially increased at the monthly periods; and during this time the abdomen enlarged, the breasts became fuller, and morning sickness was present. The patient was judged by herself and friends to be pregnant, notwithstanding the constant discharge from the womb, and as this ceased in the early part of September, and remained in abeyance thereafter for four months, during which time the other symptoms of pregnancy became more marked, there remained but little doubt as to her condition. In the third week of January of the present year (some twelve months after the commencement of her uterine troubles), labour pains came on, with free sanguineous discharge, and continued in a weak lingering form for about sixty hours (Dr. Martin was then in attendance). After this the labour was apparently arrested, and the pains ceased. The discharge, however, continued, and the patient became very ill and weak. In answer to my questions, she described the discharge as a "red, thick fluid, without much smell." In the course of a few weeks the patient got about again, and on April 5th was well enough to come over to Sheffield at Dr. Martin's wish. When I saw her all discharge had ceased, the abdomen had gradually become smaller, and the breasts shrunken. The body was tender on pressure. In the early part of May, and again a month later, she had what appeared to be a natural menstrual period. Dr. Martin agreed with me in looking on the case as one of missed labour, the cause of which was, however, not very apparent. We agreed in an attempt to reinduce uterine action, and, for this purpose, she came into the hospital, where she was seen also by my colleague, Dr. Jackson. The following is a note of her condition taken on June 12th:—A rounded, elastic, dull tumour occupies the central line of the abdomen, reaching from the symphysis pubis to a little above the umbilicus, with a breadth of about seven inches at its widest part, where it bulges over towards the left side. The tumour tender on pressure; flanks tympanitic; breasts flaccid; areolæ large and dark. A dark line down centre of abdomen. No fœtal or parietal sounds to be heard. On examination *per vaginam*, it was found that the cervix was taken up into the body of the uterus, the os externum being small, round, open, and drawn up very high. The sound passed without much difficulty or pain to a depth of four inches. Acting on the view that the uterus had been impregnated, that Nature had attempted to extrude the contents, and that from some cause, had failed to do so, I determined to endeavour to reinduce uterine action by first opening up the os uteri, and then if it seemed desirable, administering ergot. Accordingly, on June 15th, a bougie (No. 12) was passed through the os to the extent of two inches, and left in for forty-eight hours. The result of this was about nil, and on the 17th I passed a sponge tent. A few hours afterwards this was removed and two fresh ones were introduced. By this means the os was opened to the extent of two fingers' breadth, sufficiently so to admit of a better examination of the interior of the uterus. The finger could now be passed about one and a-half inches beyond the os externum, but it came in presenting part, nor bag of membranes; on the other hand, there was felt on the left side a hard, rounded, resistent body, like a small fœtal head, but separated from the examining finger by a fleshy wall, which appeared to be the side of the uterus. It thus became clear that nothing further was to be effected in the direction hitherto pursued. The fœtus, if fœtus there were, was not lying free in the uterine cavity. In the meantime, the general condition of the patient was most unsatisfactory. She had become restless and feverish, with a rapidly rising pulse and temperature. There was a fœtid discharge from the vagina, frequent vomiting, with pain and tenderness about the pelvis and abdomen, but no labour. The question now arose whether one was justified in opening the abdominal cavity, and searching further. This I felt strongly inclined to do, but thought it better to wait awhile in the hope that the patient's condition would become more favourable. I had, moreover, to contend with the ignorant opposition of jealous friends, unwilling to run an inevitable risk, and unable to appreciate, until too late, the precarious position of the patient. The further history of the case is shortly this. After local measures had been abandoned, the general condition of the patient improved somewhat for a time. Then peritonitis set in, with diarrhœa and constant sickness; eventually the body became greatly distended to such an extent as to mask entirely the presence of the tumour. Death occurred on July 26th, eight weeks after admission. A few hours after death

Digitized by Google

a post-mortem was made. A most abundant escape of very fœtid gas occurred on pricking through the abdominal walls, and on laying this fully open, a dark, gangrenous, foul space was displayed, with bits of fæces lying loose here and there amongst the intestines, and had given way in half a dozen places. There was a pint or more of dark, grumous, stinking fluid in the cavity. Occupying the true pelvis, and rising up into the left side of the abdomen, was the wasted and half-decomposed body of a fully-formed fœtus. The child lay free in the peritoneal cavity, rolled up tightly into a ball, and attached only by a dark rotten cord to the left side. One could make out little or nothing of a placenta. Where it should have been there was merely a black sloughy *débris*, in which omentum, intestine, and peritoneum were alike involved. The remains of a membranous envelope could be traced still partly enveloping the child, most distinct below, where it formed an imperfect cyst, the wall of which was intimately adherent to the iliac vessels and left ureter behind, the latter duct being considerably distended above the point of union. At the side the cyst wall lined the true pelvis, closely adherent in front, it ran into, and became incorporated with, the uterine tissue. The uterus itself was found empty, flattened down closely at the back of the symphysis pubis, to which it had been apparently glued by adhesive inflammation.

Case II.—Mrs. A. N., æt. 48, tall and thin, was married at twenty years of age, and has had one child, born during the first year of marriage. She did not become pregnant again until about ten years ago, when she had what was supposed to be a miscarriage. This was followed by a severe illness, during which she passed blood from time to time from the bowels, and suffered much from pain in the region of the pelvis. She continued in a delicate condition of health until the latter part of 1876, when the symptoms became much worse, and blood was discharged freely from the rectum. She imagined she was suffering from piles as the anus was swollen and sore. The real nature of her ailment was revealed, however, by the passage from time to time of portions of fœtal bone. She was at this time under the care of Dr. Booth, who sent the woman into the Women's Hospital (Jessop's) in February, 1877. At the time of her admission she was in a weak emaciated condition, and complaining of constant pain in the pelvis and about the anus. On examining the lower part of the abdomen, I found a firm, tender swelling occupying the right side of the pelvis. It could be felt distinctly through the vagina and abdominal wall, and appeared to be about the size of the first. Menstruation was scanty but regular. The uterus was pushed over towards the left side, otherwise it appeared normal. She had sudden and severe attacks of pain about the pelvis and rectum from time to time, with discharge of blood from the anus, and at such times on several occasions bits of bone were found entangled in the opening whence they were extracted, mostly by the patient herself. She became an out-patient in July, and continued from time to time to bring me up bits of bone voided as before. Some eighteen months ago she passed what she describes as a good handful of "white-looking clean skins," and this appears to have been the last of the delivery *per anum*. Unfortunately she threw this away without showing it to me; probably it may have been the cyst in which the fœtal *débris* was lodged. I saw the patient yesterday week. She is now in fair health and free from pain. The lump in the pelvis has disappeared, the rectum and anus appear healthy, and there has been no further loss of blood. The case has, I think, come happily to an end, and as menstruation has ceased, she may be considered safe for the future.

Department of Lunacy.

PSYCHOLOGICAL RETROSPECT.

It may interest some of our readers to give a short summary of the important psychological events which have occurred during the past year. Much discussion has taken place amongst our would-be reformers in lunacy, by agitation and writing in the medical and lay press, to induce the Government to re-frame the present lunacy laws. The question has been brought prominently before the House of Commons, but it has been shelved for consideration next session. Mr. Dillwyn introduced a Bill to which we have previously alluded. This was printed *in extenso*, and divided into numerous clauses, some good and some useless, the chief purport of the Bill being to enable the justices to purchase private asylums in their immediate jurisdiction. This clause is not, however, a compulsory one, but optional on the part of the proprietors of private asylums. In a former summary of this Bill we stated that it was inadequate, and useless for the purpose for which it was intended, and we think that this opinion is now entertained by all those who have considered the matter. The Habitual Drunkards Act has now become law, and comes into operation at the beginning of the coming year. We cannot give any opinion as to how this Act will work so as to benefit a large and, unhappily, increasing class of individuals who are addicted to an indulgence in stimulants. No establishments have as yet been opened in which chronic inebriates can be placed, though doubtless we shall ere long meet with many enterprising individuals anxious to try their skill in dealing with these cases. To these we say, pause and reflect before risking much capital on the venture, and remember that the new Act is rotten from the very bottom, and gives but little power to those undertaking the management and supervision of such cases. It is not a compulsory Act, but a voluntary one, and it is hardly to be expected that persons will, of their own accord, present themselves before a magistrate and consent to incarcerate themselves as habitual drunkards for twelve months. The clause introduced by the Archbishop of York, prohibiting such medical men as are connected with asylums from having the legal control over habitual drunkards is of itself condemnatory of the Act. The general cry of those physicians who have been largely consulted in such cases is the want of an institution where patients can be placed *nolens volens* as soon as they have proved themselves liable to be included in the category of habitual drunkards. The Commissioners in Lunacy have issued their twenty-third Report, and from this we gather that lunacy is steadily on the increase, there being 69,885 persons of unsound mind on the official register. Intemperance is again at the head of the list of causes for the lunacy, but this has unfortunately been the case for some years. The present report is a valuable one, and we have some important remarks of the commissioners given us on the condition of our lunacy laws and their general working, also on the much disputed question of private asylums; we have alluded to both of these in our columns. The Royal College of Physicians have been taxed, but whether rightly or wrongly we are not prepared to say, with refusing their Fellowship to those physicians who are connected directly or indirectly with private asylums; and the question was brought under their consideration. Some important lunacy trials by persons who have been under certificate in private asylums have been heard and decided. The first, Nunn *v.* Hemming, where the jury decided against the plaintiff without leaving the box, and the other, Nowell *v.* Williams, which lasted for fifteen days, and was also decided against the plaintiff, though, at the present moment, the verdict has been set aside on the ground of

Digitized by Google

some technical informality in admitting a letter to be put in as evidence, a rule *nisi* was granted, but this has still to be argued before it is made absolute. So much time was wasted in endeavouring to prove the plaintiff a 'dangerous lunatic," we are at a loss to understand why this term should have been introduced. It is *not* necessary to prove a lunatic to have been "dangerous" to justify his incarceration in an asylum, and we must refer the Solicitor-General to our Lunacy Act. We regret that this lawyer went out of his way in an unusual manner to vent his fury and abuse on those whom he injudiciously termed "mad doctors." We suppose, however, that a lawyer is bound to make as much as he can of a bad case, and it is part of his second nature to abuse the witnesses. Men of the highest eminence gave evidence in this case, and when we mention such names as Drs. Maudsley, Bucknill, Tuke, and L. Forbes Winslow, we must pronounce the tone taken by the Solicitor-General as unjustifiable in the extreme. Several important cases in which the testamentary capacity of an individual has been disputed have been before our courts, also criminals condemned to death, and subsequently acquitted on the plea of insanity. Among the most important and peculiar of the latter, we may mention that of Gerald Mainwaring, who murdered a policeman whilst "mad" from drink. It appears that the jury "tossed up for their casting vote, when they found that the life of the unhappy man hung upon the decision of one voter, the numbers being even, *pro and con.* This case we have also alluded to in our columns. A petition was forwarded to the Home Secretary with the arguments against the verdict, and the sentence was respited. We may mention that whenever a sensational lunacy case comes before our law courts, and the verdict given is against the plaintiff, immediately the medical proprietors of asylums are attacked by a few of the ignorant scribes. One of our contemporaries has been unusually hard upon private asylums in a series of articles. We close our last article on "Psychology" for the fast dying year with a conviction that we have done our best to uphold the rights of those gentlemen who have made insanity their special study; we have endeavoured to shield asylum proprietors from base and false inuendoes; we have brought prominently before our readers the most important lunacy data, and we trust in the coming year to again throw open our columns for the free consideration and discussion of all questions appertaining to lunacy.

THE Lettsomian Lectures for 1880, under the auspices of the Medical Society of London, will be delivered by Mr. Teevan, F.R.C.S., at 8.30 p.m., on Monday next, January 5, 19, and February 2. The subject will be the "Treatment of Stricture of the Urethra, Enlarged Prostate, and Stone in the Bladder, with special reference to recent progress."

A GREAT literary genius has just passed away in the person of Mr. Hepworth Dixon. Deceased was but 58 years of age, and was in his usual health when an apoplectic fit carried him off suddenly on Saturday last, at his residence in the Regent's Park. He was busily engaged preparing for the press the third and fourth volumes of his celebrated work "Royal Windsor," when he died.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 31, 1879.

ANNUS MEDICUS 1879.

IN taking a retrospect of the past year we cannot help feeling that it has been one of great financial depression and agricultural distress, which combined must tell upon the profession, and especially upon rural practitioners. All—or all with very few exceptions—must have felt the effects of this unexampled year—at least unexampled in our remembrance. The effects of the depression of trade and of the poor agricultural prospects have been, as we pointed out before, to cause an unusually large entry at our medical schools. Consequently the effects of 1879, as regards the profession, will be felt for some time after the general effects have been effaced by time.

The year has been sterile as regards legislative changes. The Habitual Drunkards Bill has at length been passed, and is to remain in force for ten years, during which time it is on trial. If it is found to work successfully, then it will take a permanent form. Of the urgent necessity for some such Act there can be no doubt. As to the "Medical Acts Amendment Bill," as usual, it has not been passed.

Digitized by Google

The Bill of the British Medical Association was again introduced by Mr. A. Mills; the Duke of Richmond also brought forward a Government Bill; while Dr. Lush introduced a Bill on behalf of the Medical Alliance Association. The Government Bill differs from the other two in not interfering with the constitution of the General Medical Council. The introduction of representatives of the profession in the General Medical Council was a feature in both the other Bills. The Government Bill provided for people being registered where the corporations declined to affiliate them; this was intended to open a way to the Register for female practitioners. The result of all this is that Lord George Hamilton promised on behalf of the Government that the whole subject should be considered by a Select Committee appointed for the purpose. In the Medical Council Dr. Quain proposed an amendment by which women could reach the Register without the wide and indirect clause of the Government Bill. The registry of women, and of foreigners duly qualified in their own countries, but desirous of practising in England, occupied a good deal of the time of the Medical Council. Another subject of discussion was that of a Conjoint Minimum Examination for each division of the kingdom; and last, that of a revision of the constitution of the Council. That the General Medical Council, as at present constituted, does not represent the profession, is only too certain. As to the future conduct of the corporations, Dr. Andrew Wood declared that, as far as the Scotch corporations were concerned, they would loyally abide by the decision of the Parliamentary Committee on the subject of the Conjoint Examination Scheme, whatever that decision might be.

The Select Committee of the House of Commons appointed the Right Hon. W. E. Forster as its chairman, and commenced work by first calling Dr. Acland, as President of the General Medical Council, and then Mr. John Simon. They have since taken the evidence of Sir James Paget, Sir Dominic Corrigan, Prof. Turner, Dr. Andrew Wood, and others. We sincerely trust that the work of the Committee will lead to a settlement of the vexed question of medical reform.

The position of medical men in the Services has long been unsatisfactory, and the dearth of candidates for the vacancies of late has been such, that the War Office has been compelled to face the subject. The abolition of regimental attachment, and the formation of an Army Medical Department, failed to make the Service more popular. A new Army Medical Warrant received the Royal signature on November 27th, which cancels several articles in previous warrants. Of this it is too early to speak, but it has had the effect of attracting a larger number of candidates to the examinations than has resulted for many years past. By it admission is to be by two portals, "public and open competition," and by "nomination;" retirement is to be "voluntary" and "compulsory," the latter chiefly referring to those who entered under the warrant of 1876 for a limited period of ten years' service. Exchanges may be permitted under certain circumstances. Rewards and honours are unchanged from the warrant of 1876. The Director-General may extend "sick-leave" on full pay beyond the six months granted by a medical board. Then come some arrangements about temporary half-pay, and non-effective half-pay. The whole is designed to make the Services much more attractive.

Among the events of the year are the introduction of much-needed reforms in the election of candidates for the Medical Benevolent College at Epsom.

The introduction of animal vaccination into this country has been strongly advocated recently, and Dr. Cameron introduced a Bill into the House this year for the purpose of securing it along with arm-to-arm vaccination. More recently a conference was held by the Parliamentary Bills Committee of the British Medical Association, at which Professor Warlomont, of Brussels, was present, and gave his experience of the plan in Belgium. After the expression of opinions by numerous speakers, the meeting was adjourned.

The strong tendency to make modern medicine more practical in its character, and to train the student more for the bedside and less for the examination table, is being manifested everywhere. The first object to be attained is to discover, if possible, what qualifications and capacities the youths who aspire to enter the medical profession possess; whether they are likely to make useful practitioners or not. The present entrance examinations are found not to bring out these matters sufficiently clearly, and it is thought desirable to have an examination in certain subjects at the end of the first year of medical study. Such examination, it is held, would help to weed out the idle and the incapable, those men who are a nuisance about a medical school; and who, if they ultimately succeed in entering the profession, do it little honour, and tend to lessen the faith of the laity in the practical value of medical services. The General Medical Council has issued some regulations in regard to the registration of medical students, which it believes will tend to further this end; while the Metropolitan Counties Branch of the British Medical Association has taken up the subject energetically. This subject we propose to discuss at further length in our subsequent numbers. At present we can only say that a committee was formed to investigate the matter, who issued a series of questions to teachers of medicine and surgery, and to the general practitioners of the branch. The result is that the committee recommend an examination in botany, physics, and elementary inorganic chemistry, at the end of the first year; partly in order to test each man's industry, partly to take off a part of what is now the primary medical examination. They also are strongly of opinion that each student during a part of his course of medical study should be with a general practitioner, so as to become familiar with private practice and its requirements, of which at present many men are densely ignorant, when, with their newly-acquired diploma in their pocket, they go out into the world to seek their fortune. They also were of opinion that the age of 22 should be reached before the student be allowed to go up for his diploma. Another of their conclusions was that more time should be spent by students in the wards and out-patient departments, so as to become more familiar with disease; and that they should be required to bring testimony to that effect from their teachers. At a subsequent meeting this last resolution was rescinded as being impracticable.

Digitized by Google

Certainly some means of ensuring clinical work from students is very desirable.

A second report of the British Medical Association on the action of anæsthetics gives an account of the action of the dichloride of ethidene. It appears from their experience of it that this agent does not exercise any injurious effect upon the respiratory mechanism, while the pulse becomes slower and fuller under it, and in the deepest anæsthesia it was steady and regular. There was never any pallor of the countenance, nor blueness of the lips. They regard it as possessing all the advantages of ether without its drawbacks. The Committee propose to continue their investigations, especially as regards the effects of anæsthetics upon the respiratory centres, the arterial tension, and upon protoplasm.

Of the contributions to the Societies perhaps the most interesting is that of Dr. Hughlings-Jackson to the Harveian Society on "The Diagnosis of Epilepsy," in which he marshalled the subjective sensations and the objective phenomena with much lucidity. He also pointed out the relations of the viscera to the brain, and showed how epilepsy may be caused by visceral disturbance. He stated that epilepsy proper, whether slight or severe, is rarely owing to gross inorganic disease; while epileptiform seizures frequently are so associated.

Another very important and practically valuable contribution was Dr. Matthew Duncan's paper, read to the Medical Society of London, on "Antiseptic Midwifery." He advocated an extension of the use of antiseptics in midwifery; not resorting to them merely after there was evidence of putrefactive change having gone on, but using them habitually in order to prevent septic change. He described how antiseptic injections should be resorted to, and gave elaborate instruction as to how to avoid any danger of propelling the fluid through the Fallopian tubes into the peritoneal cavity. The Cæsarian operation might be performed under the Listerian spray, as is the case with ovariotomy. Great good has come from the use of antiseptics against danger of infection from without; the further use of them will give much protection from the danger of septic action starting within the parturient patient's body. All washings of the pudenda, and dressings applied thereto, should be with carbolised materials. He also insisted upon "the carbolic hand" in obstetrics, both as regards the ordinary examination with the finger, and the introduction of the hand for the purpose of turning, or for the removal of the placenta. All instruments should be smeared with carbolised oil. He pointed to Dr. Keith's great success in ovariotomy performed antiseptically, and hoped in time to see midwifery equally successful. Of Dr. Keith's last 75 cases there has been no fatality.

At the Pathological Society there was an interesting discussion on lardaceous disease. Dr. Dickinson described it as a widely prevailing tissue change, which is shared by the blood-vessels, and the distribution of which outside the blood-vessels is regulated by their course, as if they were the channels of the morbid influence. It is nearly certain that the blood-vessels carry to the tissues a material which penetrates and infiltrates them. But his lardaceous matter has not been found in the blood. Rokitansky thought the material albuminous; while Virchow held it to be a form of starch, hence the term "amyloid" disease. Lardaceous deposit resembles fibrine which has been deprived of its alkali. Lardaceous disease consists in a general deposition of the fibrine or albumen of the blood modified by loss of alkali or gain of acid. Dr. Pye-Smith referred to the non-digestibility of lardaceous matter by which Kuhne had succeeded in separating it for analysis. At the Royal Medico-Chirurgical Society a committee was formed to inquire into the relation of croup and diphtheria; and there was an animated discussion upon the report, with the usual diversity of opinion.

In Ireland the year 1879 has been more eventful than elsewhere, as being the first working year of the new Public Health law and the era of the new Vaccination Act. The administration of the sanitary law of Ireland has been, ever since 1866, the subject of a continued contest between the boards of guardians (who are the responsible administrators of the law throughout Ireland), the Local Government Board (who ought to be the supervisors of the system), and the medical profession, who seem to be the only people having any aspirations in favour of cleanliness. The boards of guardians have been unanimously hostile to any effort towards sanitary reform, and they have been aided and encouraged in this resistance to improvement by the Local Government Board, which has lost no opportunity of delaying, discouraging, and preventing the enforcement of the Public Health law. In spite of this opposition, the medical profession, as represented by the Irish Medical Association, carried through Parliament certain amendments, the intention of which was to make the law more easy of working and more binding on all concerned. The past year has been spent in an effort to induce the Local Government Board to do its duty in enforcing these amendments, but with no better result than a mulish resistance on their part, which, it seems likely, will only be overcome by the Court of Queen's Bench, or by Parliamentary exposure.

The vaccination system of Ireland has also been amended in many important respects within the past year, by means of the Bill framed by the Irish Medical Association, and muddled by the Chief Secretary.

In the Irish Local Government Board Mr. Henry Robinson has taken the place of Sir Alfred Power, and the Poor-law medical officers are just now undecided in opinion as to whether they prefer the *régime* of King Stork to that of King Log. Everyone is, however, pretty well decided in opinion that the new leader of the department is cast in very much the same mould as his predecessor, and is an autocrat of the ordinary official type, and nothing more.

The King and Queen's College of Physicians has obtained a new charter, which creates a new order of members in addition to that of Licentiate and Fellow which have hitherto existed. This proceeding does not seem to have had any *raison d'être*, save to gratify those alumni of the College who like a higher title without—in reality—giving them any privileges, or making them members of the corporation in any true sense. The new charter leaves the whole administration and authority of the

Digitized by Google

College in the hands of a small self-elective body of Fellows whose qualification for office is a secret vote.

The ill-health of Dublin reached such monstrous proportions within the past year, that even the Corporation and its medical officers could no longer conceal or explain away the existence of a terrible mortality within the city. After a doze of some eighteen months, the Chief Secretary was awakened by the public clamour to sufficient consciousness of the facts to admit of his appointing a Royal Commission, and at the same time trying to tie their hands regarding the scope of their inquiry. But thanks to the determination shown by the Commissioners—Mr. Rawlinson and Dr. MacCabe—and the activity of the Sanitary Association, the investigation was not burked, but was pursued to a satisfactory termination. Its most notable incident was the extraordinary change of front of the Corporation, who, having been for years obstinate in its assertion that the mortality and unhealthiness of the city were all moonshine, now threw itself into the arms of the sanitary reformers, and offered to the Commissioners a most complete and abject recantation. The Report has not yet been presented, but we have every reason to believe that it will bring comfort to the enemies of dirt and disease.

The new Irish University Bill has become law within the year, and—*par consequence*—the Queen's University ceased to exist as a medical licensing body. Perhaps we shall best express the feeling of the profession upon this event by the motto "*De mortuis.*" In any case, the establishment of a new University cannot but be pregnant of interest and importance to the profession. If the new institution gives its medical and surgical degrees upon a full and sufficient education and examination, it will give to Ireland benefits which it has never yet possessed. If, on the other hand, it seeks to attract students by the distribution of cheap and nasty qualifications, it will be an incubus and a drag upon the progress of the Irish School of Surgery and Medicine.

The British Medical Association held its annual meeting at Cork, under the presidency of Dr. C'Connor, President of the Queen's College. Dr. Hudson delivered the address in Medicine; Dr. Fergus that in Public Health; while Mr. Savory delivered the address in Surgery, the latter criticising Listerism in a well-arranged address. The meeting was a very successful one, in spite of the long journey and the bleak, wet summer; the visitors carrying away with them pleasant memories of Irish hospitality, and of the scenery in Kerry.

In Scotland substantial manifestations of sympathy have been extended during the year to several members of our profession who lost their all through that crushing commercial calamity which befell the country, the failure of the City of Glasgow Bank. Notably is the case of Dr. Adams of Glasgow, who was presented by a few friends and patients with his residence, at a cost of about £2,000. Dr. Fergus, of the same city, was presented with his portrait by a distinguished artist, and several valuable articles of plate, at a meeting of some of the most influential citizens, and touching allusion was made to his severe loss. The sympathy thus evinced was alike creditable to the public as to the profession. Almost all the others who similarly suffered are now working at their profession with their pristine devotedness to it; and it is sincerely to be hoped that if time does not permit them the repossession of their means, they will at least attain to that peace of mind and resignation which are far better, and which so certainly spring from honest labour and the consciousness of well-doing. In the management of the medical institutions of Glasgow there are indications of enlightened reform. By the regulations relating to the Royal Infirmary, which the late Dr. Fleming was mainly instrumental in bringing about, the physicians and surgeons to this institution were practically regarded as appointed for life, and made their arrangements accordingly. It is understood that the directors, recognising now the unfairness of any such arrangement to the profession generally, and the possible detriment to medical science, have resolved that the appointment of physician or surgeon to the Royal Infirmary shall not be held longer than for *fifteen* continuous years, and that there shall be one year of ineligibility. Even this period of incumbency in the case of many of the present holders of office may be considered too long. This step is, however, one in the right direction, and will be hailed with satisfaction by the great majority of the profession. The directors of the Glasgow Maternity Hospital have also wisely resolved that the post of physician-accoucheur shall not be held for a longer period than four years, a year of ineligibility also intervening in this case. It is extremely desirable that men of acknowledged ability be secured for these offices.

Among the most important contributions to our knowledge of therapeutic agents of the past year is the work of Prof. Rutherford, F.R.S., as to the action of certain drugs upon the liver. It was found that taraxacum exercised but a feeble influence upon the liver, while ipecacuanha was found to exercise a powerful stimulating action on the secreting apparatus of the liver. Prof. Rutherford is inclined to hold that the good effects of ipecacuanha in dysentery are due to its action upon biliary secretion. Experimentation has established the action of nitro-hydrochloric acid as a hepatic stimulant of considerable power. The research into the action of sulphate of soda as compared to that of sulphate of magnesia, revealed some very instructive information. It was found that while the magnesium sulphate acted energetically upon the intestinal secretions, it exercised no influence upon the hepatic secretion. On the other hand, the sodium sulphate acts powerfully upon the liver, increasing the secretion of bile. This vindicates the preference some practitioners have manifested for sulphate of soda as against sulphate of magnesia in cases where it is desirable to stimulate the biliary, as well as the intestinal, secretions; despite the less disagreeable taste of the magnesium sulphate. Then it was found that colchicum is a powerful hepatic, as well as intestinal stimulant in the dog; and probably it has the same action upon man. Aloes exercised a very energetic action; while rhubarb, generally credited with a powerful action upon the liver, was found to be less potent than supposed, but still certain. Hydrastin, euonymin, and other comparatively new remedies, were found to be hepatic stimulants likely to be useful in practice. As to the action of mercury, some valuable information is afforded. It was found that calomel did not increase the

Digitized by Google

elimination of bile, while it increased the action of the intestinal glands; but that the corrosive sublimate acted energetically upon the liver. The experiments did not throw any positive light upon the hypothesis that some portion of the calomel swallowed is converted in the stomach into the perchloride; but it was found that by the addition of a tiny dose of the perchloride to a dose of calomel the liver of the dog is powerfully stimulated. Prof. Rutherford distinctly asserts that the experiments were performed to ascertain the effects upon the *bile-secreting* rather than the *bile-expelling* apparatus. As regards the latter, he does not profess to have ascertained anything of value. As regards other medicinal agents, salicine, and, still more, salicylate of soda, have been largely employed, and their action watched; but though certain clinical facts have been fairly established, the *modus operandi* of the action of salicine is shrouded in as much mystery as ever. The subject of the antagonistic action of certain drugs is attracting more attention; and a case occurred at the Leeds Infirmary where the injection of a quarter of a grain of sulphate of atropia saved the patient's life in opium poisoning, when everything else had failed. The use of belladonna for the arrest of the night sweats of phthisis is on the increase; and it is found that the addition of a full dose of sulphate of atropia to a dose of morphia when the sleep is broken by cough, prevents the profuse perspirations which are apt to follow the administration of morphia alone.

One of the most valuable contributions of the past year is that of Dr. William Roberts, of Manchester, on the digestive ferments. After explaining the normal ferments in the saliva, the gastric juice, and the pancreatic secretion, he points out how we may apply this knowledge practically. In the diastase found in large quantities in malt and malt extracts we find a means of increasing the action of the saliva upon starch. But as the action of the salivary secretion and the malt diastase are alike arrested in the presence of the acid in the stomach, it is necessary to add the maltine to the starchy mass a little time before it is swallowed. By the use of pepsine it is possible to materially assist gastric digestion when the secretion of gastric juice is defective. The gastric juice dissolves albuminous bodies, converting them into peptones by a process of hydration allied to the hydration of starch by diastase, which converts it into sugar. But the great matter he ably illustrates is how to utilise the digestive ferments of the pancreatic secretion. After the food has passed the acid stomach it becomes alkaline, and then the conversion of starch into sugar goes on again under the influence of pancreatic diastase; the albuminoids are further digested by the action of trypsin, a pancreatic ferment which is active only in an alkaline medium; further, fat is emulsionised by the pancreatic secretion. In cases of greatly enfeebled digestion milk can be digested to a great extent before it is swallowed without losing its appetising qualities. A very nutritious compound can be made by adding some active pancreatic extract to a mixture of gruel and milk, with some bicarbonate of soda. By such means the body may be fed when the stomach and digestive powers are greatly enfeebled, and in fevers, in acute inflammations, in diseases of the stomach itself, such artificial digestion promises to be of priceless value. But to this subject we will return before long.

During the year much attention has been given to health resorts at high altitudes in the treatment of phthisis. Of their utility there can be little doubt; but it remains to be seen whether health resorts at home, with English comforts and rational treatment, will not be equally useful to a class of patients who cannot well proceed to a Continental health resort. As to the views held that the conditions of these health resorts are such as to be themselves sufficiently curative, and that medicinal and dietetic treatment in early phthisis are not required, we beg to enter our most earnest protest. Patients are led away with the idea that a residence at the coveted spot is all that is required; that a winter spent at Davos, for instance, is the treatment *par excellence* for early phthisis; and that if a cure has not been attained the patient may go there another winter; and that such procedure does away with the necessity for appropriate medicinal treatment, especially during the intervening summer; such views may be all very well for the medical men residing at these health resorts, but the hollowness of their claims to our respect is only too apparent.

The subject of typhoid fever has attracted attention this year both by the publication of Surgeon-General Gordon's report on Typhoid Fever in the British Army in India, and by Sir Wm. Jenner's address on the Treatment of Typhoid Fever, delivered at the Birmingham Medical Institute. As this is Sir William's first utterance on the treatment of a disease with which his name is so indissolubly associated, it has been much spoken of. He holds that there exist no means of cutting the fever short. The food should be liquid, and should not consist too largely of milk—broths, vegetable juices, strained fruit juices are to be used; and grapes to be rejected on account of their skins and stones. If milk be not digested the curd is apt to do much mischief. If the bowels are confined they should be opened by simple enemata. Small doses of mineral acids, he thinks, are useful. Opiates are to be avoided. He treats the diarrhœa chiefly by food; a little sulphuric acid being given when the fluid stools are too alkaline. He is not opposed to resort to alcohol in fit doses; and he thinks it good to keep the intestines empty. Where there is hæmorrhage he advises rest: starch enemata, with a few drops of laudanum and some acid by the mouth, are also of service. He thinks loose stools associated with superficial ulceration of the bowel; while constipation suggests a single small deep ulcer. The faintness due to hæmorrhage is not to be treated by stimulants, for obvious reasons. He is not convinced of the value of the cold bath treatment: nor of the value of quinine or salicylate of soda to reduce temperature. He trusts rather to the powers of Nature than to energetic treatment.

Among the new books and new editions which have proceeded from the press this year, we have the fifth volume of Reynold's System of Medicine, completing the series; a new edition of Professor F. Roberts's well-known Handbook of the Theory and Practice of Medicine; of Billroth's work on Surgical Pathology; of Leishman's Midwifery; of Sir Henry Thompson's work

Digitized by Google

on Diseases of the Urinary Organs; of Milner Fothergill's work on the Heart and its Diseases, including the Gouty Heart, a really new book; of Bucknill and Tuke's Psychological Medicine; and of Habershon's Diseases of the Stomach. Of new works, there are Dr. R. E. Thompson's Physical Examination of the Chest; Guttmann's Handbook of Physical Signs, translated for the New Sydenham Society; Heath's Students' Guide to Surgical Diagnosis; Morris's Anatomy of the Joints of Man; Matthews Duncan's Lectures on Diseases of Women; Emmet's Gynæcology; Galabin's Students' Guide to Diseases of Women; Gowers's Manual of Medical Ophthalmology; Austin Flint's Clinical Medicine; Eulenberg and Guttman's Physiology and Pathology of the Sympathetic System of Nerves; St. John Roosa's Diseases of the Ear; George P. Field's Diseases of the Ear; Nettleship on Diseases of the Eye; Watson on Eyeball Tension; Whistler on Syphilis of the Larynx; Dowse on Syphilitic Diseases of the Nervous System; Morell Mackenzie on Diphtheria; while of works on Treatment, a new edition of H. C. Wood's Therapeutics; another of Bartholomew's Materia Medica and Therapeutics; Harvey's First Series of Therapeutics; Naphey's Modern Medical Therapeutics, Naphey's Modern Surgical Therapeutics, both in their sixth edition; Handsel Griffiths's excellent Manual of Materia Medica and Pharmacy, the author, a rising Dublin physician, having died suddenly before putting his work to press; and Fenwick's Outlines of Medical Treatment, have appeared. An excellent and valuable memoir of Comparative Anatomy is provided in the work of Gegenbaur, translated by Jeffry Bell, under the supervision of Prof. E. Ray Lankester, F.R.S.

We regret to have to record so many deaths of well-known members of the profession during the past year. Among those who have died in 1879 we find J. Macrobin, Emeritus Professor of Medicine in Aberdeen; Dr. J. G. Fleming, Ex-President of the Faculty of Physicians and Surgeons of Glasgow, and Dr. Coats, long its treasurer; E. Ledwich, Senior Surgeon to Mercer's Hospital, Dublin; the accomplished and respected Charles Murchison, LL.D., F.R.S., Physician to St. Thomas's Hospital, and Lecturer on Medicine in the School, a man of rare endowments and industry, whom the profession honoured and could ill afford to lose. Shortly afterwards with the same disease, aortic valvulitis, Tilbury Fox died in Paris, where he had gone for a little relaxation. His death gave the finishing blow to his aged father, Luther Owen Fox, of Broughton, Hants, one of the best known and ablest country practitioners south of the Thames, who had long been in declining health. Charles Maunder, the distinguished operator, and Surgeon to the London Hospital, followed; then Inspector-General Domville; then Geo. W. Callender, the well-known Surgeon to St. Bartholomew's Hospital, died on board ship on his way back from a tour in the United States. Arthur Leared, Senior Surgeon to the Great Northern Hospital, an accomplished Icelandic scholar, succumbed to an attack of typhoid fever, the seeds of which were sown in Morocco, from whence he had just returned when he felt ill. Then following—Dr. P. Black, Senior Physician to St. Bartholomew's Hospital; very recently in the South of France, whither he had gone for his health, died Soelberg Wells, Ophthalmic Surgeon to King's College Hospital. Later still Dr. Harry Leach, the well-known Medical Officer of the Port of London, so long connected with the *Dreadnought*. Of less well-known worthies the deaths have been numerous, and amongst them "Diana Smith," the heroic surgeon to the whaler which was caught in the ice in September, 1865, without preparations for staying the winter, and whose "race with death" after she was blown out of the ice with gun-powder, forms one of the saddest stories of human suffering. Also James Charlesworth Copland, the bearer of a distingaished medical name, a much-respected member of our editorial staff; a profound scholar and observant man, whose sterling worth merited honours which his retiring disposition shrank from. Others there are, if our space would only permit of our mentioning them.

Of the year 1879 it can only be said that it has been an unfortunate year in every way. Bad weather, agricultural and commercial depression, a satisfactory medical Bill unattained, few high-class books, and a heavy death-roll; these are its characteristics. May we trust, then, 1880 will bring with it better times, brighter days, and blither prospects.

Notes on Current Topics.

Arsenical Contamination by Vapour.

Professor Foster read a paper on Monday evening week at the Medical Society of London "On the Contamination of Atmospheric Air by the Vapour arising from Arsenical Pigments." The experiments made to determine this question proceeded on the old lines laid down by Phillips some twenty years ago, and the results obtained, as might have been expected, were quite of a negative character—that is to say, they were conducted under conditions so totally different to those met with in every day life, and therefore no truly reliable answer could be looked for. A few glass bottles containing an arsenical pigment being kept for some hours or days in a temperature of 100 deg. F., whilst the aspirator tubes and test remained exposed to ordinary changes of the atmosphere were expected to solve the very difficult problem of poisoning by volat ilisation of arsenite of copper. Dr. Hamberg, an eminent Swedish chemist, came to the conclusion that the gaseous matter evolved was a very important factor in poisoning by wall papers; but then his experiments were carried on in a room of the house in which he lived, and the paper having been on the walls for a quarter of a century. He was rather susceptible of the action of the poison, and observed that the colouring matter of the paper had gradually undergone an alteration. No attempt was made by him to increase the temperature of the room, and with the exception that the doors and windows of the room in which he had arranged his apparatus were more carefully closed, all went on as usual.

It has never been suggested that the peculiar symptoms arising from wall-paper poisoning are due to the vaporisation of arsenious acid or arseniuretted hydrogen. We have the clinical fact that poisoning takes place by wall

Digitized by Google

paper, and whether by dust or gas it matters not. There is doubtless considerable difficulty in suggesting a perfectly satisfactory theory for the poisonous action of arsenical pigments upon those who are most susceptible to their influence; but is there not quite as much difficulty in attempting an explanation of the action of lead—how by reason of having slept in a room the walls of which have been freshly painted, lead paralysis ensues? Chemists have as yet been unable to detect lead in the form of either a carbonate or oxide in the air of the room in such cases. Nevertheless the fact of rapid lead poisoning by such means is a well-established fact.

Hydrofluoric Acid in Diphtheria.

Mr. Henry Bergeron has obtained very favourable results from inhalations of an atmosphere containing a definite small proportion of hydrofluoric acid gas. The quantity employed is one gram for each cubic metre (1·3 cubic yards) of air space in the room during three hours. The gas is generated by allowing the proper amount of acid slowly to evaporate from a vessel (of lead) placed on a table a short distance from the bed of the patient.

Removal of Trichinæ.

Dr. Hæberlein reports that an apothecary in Crailsheim, Mr. Blezinger, found alcohol, as well as salicylic acid, in quantities of 10 to 15 grams (⅓ to ½ oz.) to cause the rapid disappearance of trichinæ. Thinking to be able to preserve human flesh and pork containing trichinæ by means of salicylic acid, he sprinkled the latter, in powder, over the specimens, but found shortly afterwards that the trichinæ had entirely disappeared.

If this information is authentic it might be worth while to try the effects of salicylic acid upon persons infected with trichinæ.

Fracture of the Third Cervical Vertebra.

Dr. H. F. Eberman publishes in the *Amer. Journ. of Med. Science* a very singular and interesting case of fracture of the third cervical vertebra.

The patient, æt. about 70 years, was making his home in a stable adjoining an hotel, and was in the habit of sleeping in the hayloft. One morning on arising, and while descending the steps, he slipped and fell, striking his occiput violently on the ground, and thus forcibly throwing his head forward on his chest, and rendering him insensible for a considerable time.

After recovering from the shock he arose, and placing both hands to his neck, walked to the bar-room of the hotel (which is half a square from the place of accident), where he remarked that he thought his neck was hurt, and at the same time called for a glass of whisky, which he immediately drank. He then returned to the stable, laid down on the hay, and expired in about half-an-hour.

On post-mortem examination the third cervical vertebra was found to be fractured transversely through the body, the arch on the right side was broken entirely through, the articulating surfaces on both sides were fractured through the middle, the transverse process on the right side of the atlas was broken off, and the interspinous and posterior vertebral ligaments were ruptured, but the spinal cord remained intact.

The Responsibilities of Insanitation.

A case has recently been decided by Mr. Justice Fry which is likely to have very beneficial sanitary effects. A Captain Cutter took a house near Hanwell from a Mr. Mantell, and after some correspondence, in which Mr. Mantell's house-agent — a Mr. Hill — gave satisfactory assurances respecting the sanitary arrangements of the establishment, the tenant went with his family into the residence. This was in September last, and in the course of the two months following one of Mr. Mantell's children and his sister-in-law died of diphtheria. Mr. Hill had positively stated in a letter that there were no cesspools on the premises, and that the closets were supplied from a cistern distinct and separate from that which supplied the house with water for drinking and cooking. Mrs. Cutter had made particular inquiries on these points, for she had heard, as she stated in her correspondence with the agent, that there had been illness and death among previous occupants by the defective drainage. Both of the agent's assurances on the above points turned out to be erroneous. The cistern for domestic purposes was not independent of that which supplied the closets, and there was indeed, at some distance from the house, but still on the premises, a cesspool into which a portion of the house drains emptied themselves. When these facts were ascertained, Mr. Mantell took the action in question, and sought not only to set aside the agreement for a lease, but to obtain damages. Mr. Justice Fry gave judgment that the contract should be rescinded, and directed an inquiry as to the amount of damages to be awarded to Mr. Mantell. This judgment will clear up certain obligations of lessors of houses, respecting which obligations we have reason to believe considerable uncertainty has hitherto prevailed. All that is necessary is for the intending occupant to take the simple precaution of obtaining from the landlord or his agent a written statement—it need not be stamped or couched in legal jargon—that the drains and other sanitary arrangements are in a fit and proper condition. A lessee who will not take the trouble to make inquiries must be held to undertake willingly the risks of his house turning out a trap for the disease and death of its inmates.

Spring-top Gloves.

The present fashion of wearing "spring-top" gloves, has led to several somewhat serious accidents, and it is well that those who adopt them into use should be warned of the possible dangers they run. As usually made, the spring consists of two pieces of iron united by a hinge joint. The sharper ends of these irons are at the wrist end of the glove, and meet immediately above the palm. Being rigid and unyielding they act as a pair of blunt-pointed probes when directed into the flesh, and in case of a fall on the hand, particularly if it be a little bent on the arm, they are capable of doing very considerable mischief. Ordinarily the spring is covered over with a fur lining, but this wears, and goes at the ends after more or less use, thus exposing the tips in the situation most favourable for effecting injury. The greater convenience attending the use of these gloves has brought

Digitized by Google

them into general wear, and the greater need, therefore, is there, that caution should be exercised about them. The plan of placing the spring on the back of the hand, is little less objectionable; but it is better to avoid the dangerous arrangement altogether. A spring armlet has recently been introduced as a fastening. This is less liable to do damage in cases of accidental fall than the arrangement we condemn.

The Davis Osteological Collection.

Dr. Barnard Davis's collection of skulls and skeletons of various races of men will, in all probability, become the property of the Royal College of Surgeons. It has been offered to that body for £1,000, and a general feeling prevails in the Council that the opportunity of acquiring such a rich and extensive collection should not be lost. In case the funds of the College should be thought in a condition too low to justify the immediate outlay of so considerable a sum, several offers of assistance from private individuals have been made; and in the interests of English science it is to be devoutly hoped that no untoward incident will prevent the accomplishment of the purchase. The value of Dr. Davis's collection is enhanced by the catalogue which has been most carefully made of it, and called "Thesaurus Craniorum." The ultimate decision of the Museum Committee of the Royal College of Surgeons, which has been deputed to consider the question of purchase, will be anxiously awaited by all who appreciate the importance of the study of comparative osteology.

Dr. Richardson's Legacy.

Dr. B. W. Richardson contributes an article to the January number of *Macmillan's Magazine*, in which he describes the history of the bequest made to him by the late Sir Walter Trevelyan, of Wallington. Ingenuously admitting the difficulty he is under of fulfilling the terms of the will, which direct the wine to be applied for scientific purposes, Dr. Richardson is compelled to declare his inability to do anything, immediately, with it; and it is apparently doomed to remain as much longer *in statu quo* as it formerly did in the cellars of the deceased baronet. But little benefit could be expected to arise out of comparative trials of the various liquors, numbering in all twenty-one kinds, and any useful application of them is barred by the conditions under which they are left. But it is still within Dr. Richardson's power to devote the stimulants to charitable purposes, and by exhausting them in hospital use, it might even be urged that the intentions of the testator were not violated. When something might be done with the gift, it seems a pity that the opportunity should be let slip.

Police-Office Accommodation for the Sick.

In only a few police offices is there any adequate arrangement existing for the proper and immediate treatment of such persons as are taken into custody by the police while ill, or immediately preceding illness. Cases illustrating the necessity for accommodation of the sort, are constantly being reported, and very many deaths are annually to be attributed to the deferred treatment which such prisoners receive. Dr. Hearne recently drew the attention of the magistrate to the matter at the Southampton Police Court, in connection with the death of a woman, who, having been brought insensible to the police station, was thence removed to the poorhouse, where she died. It was stated that objections are raised against the practice of transporting such persons to the workhouse; but, as Dr. Hearne contended, with the wholly inadequate means of relieving them afforded by the station, no other course is open. The cells were described as quite unfit to put people in; and as being dangerous to lock prisoners in, during the hot weather. This state of things, however, is by no means peculiar to Southampton; and it is highly necessary that some steps should be taken, ere long, to remedy an evil that is to blame for no inconsiderable number of preventible fatalities.

Domestic Electric Lighting.

The continued endeavours of Mr. Edison to obtain an electric lamp for domestic use appear to have been at length crowned with success. We are informed that the inventor "has perfected an electric lamp of extraordinary simplicity, costing only 25 cents, with which he proposes a general illumination of the village of Menlo Park on New Year's Eve. He has discovered that a steady, brilliant light is obtained from the incandescence of mere carbonised paper better than from any other known substance. Strips of drawing paper in horse-shoe form are placed in a mould, and baked at a very high temperature. The charred residuum is then attached to the platinum wire and hermetically sealed in a glass globe from which the air has been exhausted. This attached to a wooden stand, or ordinary gas fixture, is the whole lamp. No regulating apparatus is required, the flow of electricity being automatically increased and diminished at the central generating station. A single generating machine of simple construction, and applicable for domestic use, supplies about fifty lamps. The cost of the power is not stated. The quantity of electricity supplied to each house-holder is measured, by the deposit of copper particles in an electrolytic cell. The probability of the electric light being employed generally for house illumination will re-open the discussion, never definitely conclusive, respecting the effects, injurious or other, on the eyes. Some more decisive opinions should be possible now, seeing that the light has been for a considerable time in constant use in several business establishments in this and other countries. The desirability of its introduction to replace gas is apparent.

The London Fog.

During Christmas week the metropolis was visited by one of those fogs for which it is famous, and if there be any relief in a scientific explanation of a disagreeable infliction, it may be found in one by Professor Frankland. Noting that the persistent and irritating fogs which affect large towns frequently occur in comparatively dry air, he explains this persistency in a dry medium as due to the formation of a coating of coal oil, derived from coal smoke, upon the surface of the minute particles of water which compose fog, and which coating effectually prevents the

Digitized by Google

evaporation of water. The remedy would therefore appear to lie in the use of a smokeless coal or of gas for heating purposes.

The Health of Dublin.

THE deaths registered in Dublin during the week ending the 20th inst. represent an annual mortality of 48·9 in every 1,000 of the population.

The average annual death-rate in eight large town districts of Ireland (including Dublin) last week was 42·1, in Belfast 40, and in Cork and Galway 45.

In 20 large English towns, inclusive of London (in which the rate was 28·9), the death-rate averaged 30·5; in Glasgow, 31·3; and in Edinburgh, 21·9.

In Dublin the deaths numbered 296.

One hundred and ten of the persons were under 5 years of age (52 being infants under 1 year old), and 84 were aged 60 years and upwards, including 39 persons aged 70 and upwards, 11 of whom were octogenarians, and 1 (a woman) was stated to have been aged 90 years.

There were 58 deaths from zymotic diseases registered, being 10 more than in the preceding week, and 25 over the average number for the 51st week of the last 10 years; they comprise 4 from small-pox, 16 from measles, 10 from scarlatina, 6 from croup, 7 from whooping-cough, 7 from fever (3 typhus, 3 typhoid, and 1 simple continued fever), 2 from diarrhœa, &c.

The registered deaths from small-pox (4) are 2 over the number in the preceding week, and the new cases of the disease admitted into the Dublin Hospitals, which had fallen to 11 in that week, rose to 19 last week; 26 patients were discharged during the week, 2 died, and 61 remained under treatment on Saturday, being 9 less than the number in hospital at the close of the previous week.

The deaths from measles (16) are more numerous than in any other week of the current year; 6 took place in the Ringsend and Irishtown portion of Donnybrook district, where 5 of the deaths from this cause, registered in the week ended 13th inst., occurred.

The number of deaths (10) from scarlatina is the lowest recorded since the week ended 8th November; but the number (7) from whooping-cough is the highest weekly number registered this year.

The Registrar-General.

ONLY the most intense surprise, mingled with regret, can be felt at the lamentable want of foresight which has induced the Government authorities to overlook the incontestable claims of Dr. Wm. Farr to the office of Registrar-General, vacant by the resignation of Major Graham. It is impossible that the Government can be ignorant of the essential nature of the work done by Dr. Farr in bringing the registration returns to the pitch of excellence they have attained; or in case this is so—a most unlikely probability—then it reflects most discreditably on the general intelligence of those concerned. In any other case, however, this tacit ignoring of the inestimable value of Dr. Farr's great works is a painful surprise to all who are interested in the progress of the statistics of medicine and hygiene. By the appointment of a gentleman whose name is entirely unknown as that of a scientific man outside the ranks of his own immediate friends, and thus superseding a public servant who has worked long and successfully in the public cause, the Government have shown a careless disregard for the hygienic welfare of the country that we can only hope may not be quickly productive of very serious evils to the community at large.

Army and Naval Examinations.

IT is announced that examinations of candidates for commissions in the medical service of the Royal Navy will be held in February next, further particulars regarding which will be duly announced; also that an examination for the medical department of the army will be held at the London University on the 9th February next, and following days.

MR. BELL, one of the two clerks to the General Medical Council from its existence, died a few days since. Deceased has been ailing since his discharge from office last year, feeling acutely the position such discharge entailed.

THE first step towards the establishment of the post of Public Prosecutor has just been taken by the issue of a circular from the Home Office, stating that Mr. Maule, Q.C., will, from the 1st of January, be appointed Director of Public Prosecutions for England and Wales.

IT having been decided, at a public meeting of the inhabitants of Eastbourne, to erect a hospital to the memory of the late Princess Alice, a sum of £2,000 has been subscribed, leaving about a similar amount to be contributed. The hospital is to be named the Princess Alice Memorial Hospital.

THE *London Gazette* of last week contains the last distribution of honours for the Zulu campaign; the appointments made are to the Most Distinguished Order of St. Michael and St. George, and amongst the names of those officers selected for the decoration we find that of Surgeon-General John A. Woolfryes, M.D., who is already a Companion of the Bath.

IT has, we believe, been decided that the form which the English memorial to the late Princess Alice shall take is the endowment of the Hospital and School for Nurses in Darmstadt, which her late Royal Highness founded. The surplus, after the endowment of the Hospital, will be given towards the maintenance of other kindred institutions in which the Princess was personally interested.

THE deaths in London referred to diseases of the respiratory organs, which in the ten preceding weeks had increased from 190 to 777, further rose last week to 799, and exceeded the corrected weekly average by 288; 549 resulted from bronchitis, and 167 from pneumonia. So great a fatality from these diseases has not been recorded in London since the end of 1874.

THE death-rate last week from the seven principal zymotic diseases ranged from 0·8 and 1·2 in Portsmouth and Norwich, to 6·5 in Nottingham, 7·6 in Dublin, and 8·2 in Liverpool. Scarlet fever showed the largest propor-

Digitized by Google

tional fatality in Newcastle-upon-Tyne, Bristol, Liverpool, Dublin, and Sunderland; and measles in Plymouth, Nottingham, Liverpool, London, and Leeds. Small-pox caused but 2 deaths in London.

Last week the rates of mortality per 1,000 in the principal large towns of the United Kingdom were—Brighton 17, Portsmouth 18, Sunderland 20, Edinburgh 22, Norwich 23, Bradford 23, Leicester 24, Sheffield 24, Leeds 25, Hull 25, Birmingham 26, Newcastle-upon-Tyne 26, Oldham 27, Glasgow 31, Wolverhampton 31, London 32, Salford 32, Nottingham 33, Manchester 36, Plymouth 37, Bristol 39, Liverpool 40, and the highest rate Dublin 49 per 1,000 of the population.

In the principal foreign cities the rates of mortality, according to the most recent weekly returns were—in Calcutta 30, Bombay 35, Madras 45; Paris 34; Geneva 25; Brussels 34; Amsterdam 27, Rotterdam 32, The Hague 30; Copenhagen 36; Stockholm 23; Christiania 19; Berlin 22, Hamburg 27, Dresden 22, Breslau 27, Munich 31; Vienna 27; Buda-Pesth 28; Rome 41, Turin 33; Alexandria 34; New York 22 per 1,000 of the population. The deaths from small-pox in Paris which had been 29 and 28 in the two previous weeks, rose last week to 51; 38 deaths were also referred to typhoid fever in this city.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

Health of Edinburgh.—For the week ending the 20th inst. the mortality of Edinburgh fell from 106 to 91, and the death-rate thus stands at 22 per 1,000; 44 of the deaths were due to diseases of the chest, and 27 died above 60 years. The zymotic mortality was low, while the birth-rate was high.

St. Andrew's University.—After a very keen contest Dr. Benjamin Ward Richardson was re-elected on Saturday, the 20th inst., to the office of Assessor of the University Council, a post which he has already held for several terms. His opponent was Dr. Carpenter, ex-registrar of the London University. About two-thirds of the constituency polled, and the numbers were—Richardson, 542; Carpenter, 481.

Registrar-General's Returns.—The weekly return of births, deaths, and marriages for the week ending Saturday, December 20th inst., says:—The death-rate in the eight principal towns during the week ending Saturday, the 20th inst., was 28·5 per 1,000 of estimated population. This rate varies little from that of the preceding week, but is 5·3 below that for the corresponding week of last year. The lowest mortality was recorded in Greenock—viz., 18·9; and the highest in Paisley—viz., 39·3. The mortality from the seven most familiar zymotic diseases was at the rate of 3·7 per 1,000, almost the same as last week. Scarlet fever and whooping-cough appear to be the most prevalent. Acute diseases of the chest caused 247 deaths, or four above the number recorded for the previous week.

Glasgow Death-Rate.—The death-rate of Glasgow for the week ending the 20th inst. was at the rate of 31 per 1,000 per annum, against 31 in the preceding week, and 38, 27, and 24 in the corresponding weeks of 1878, 1877, and 1876.

The Managers of the Royal Infirmary, Edinburgh.—The following requisition has received over a hundred signatures:—Requisition from Contributors to the Royal Infirmary to Mrs. Russel, 4 West Circus Place; Miss Eliza Wigham, 5 South Gray Street. Ladies,—In view of the fact that nearly half of the patients and the whole nursing staff of the Royal Infirmary are women, we believe it to be highly desirable that at least two or three women should have seats on the board of management, and we think the present a peculiarly suitable moment to inaugurate such a measure, when the institution has just taken possession of its new premises, and has received in every quarter the most liberal support from contributions of both sexes. It happens, moreover, that at the forthcoming election it will be necessary to elect some new representatives of the court of contributors, as several of those now sitting are not eligible for re-election. Under these circumstances, we, the undersigned contributors, desire very earnestly to request your permission to place your names in nomination for election as infirmary managers at the annual meeting in January next.

Special.

FRANCE.

(FROM OUR OWN CORRESPONDENT.)

Paris, Dec. 15th.—For a long time the employment of chlorate of potash in the treatment of epithelioma has been proposed, but although some happy results were obtained, this treatment did not seem to gain many partisans. In one of the last meetings of the Therapeutic Society, M. Féréol cited three cases of this disease treated by this salt. In one case a gentleman came to consult Nélaton for a tumour on his lower lip, which the eminent surgeon speedily recognised as epithelioma. An operation was proposed, but postponed for a fortnight, in order to try the effects of the application of chlorate of potash. The treatment consisted in applying several times a day a collutory composed of honey and the salt, taking care to cover the tumour afterwards with a piece of fine linen in order to prevent the contact of the lips. At the end of the fortnight the appearance of the disease was so improved that the operation was considered unnecessary. On continuing the treatment the tumour entirely disappeared. M. Féréol in his hospital practice has had many opportunities for trying chlorate of potash in the above disease, and never had reason to regret its employment. But instead of a collutory or solution he applies directly upon the ulcer the salt in fine powder, the application being renewed every three days—at the same time he administers internally from a scruple to half a drachm of the same salt daily.

At the Surgical Society, M. Richard read a paper on the Treatment of Naso-pharyngeal Polypus by the injection of a solution of chlorlde of zinc. He cited a case in which a lad entered the hospital to be treated for epistaxis. On examination a large naso-pharyngeal polypus was observed compressing the velum and hindering deglutition. An operation having failed, the tumour was injected with a few drops of the chloride of zinc solution. At the end of a few days a large white slough was detached, and the injection was renewed. In three weeks the lad left hospital cured.

We have had very severe weather for the last week; snow fell in great quantity, and the misery which has been very great amongst the poor, is accordingly accentuated, as all out-door labour is at a standstill. The cold is intense, the thermometer marking 14° degrees below

Digitized by Google

freezing point (Centigrade). Many deaths have occurred from this sudden lowering of the temperature. Two men who were employed in the streets in sweeping the snow fell dead suddenly yesterday from the exposure. The hospitals are full, every available space being occupied

Correspondence.

SOME QUASI-MEDICAL POPULAR FALLACIES OR BELIEFS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Familiar for many years back—ever since, indeed, I became aware of the import of such a question—with the fact that the masses are widely possessed of a belief in the efficacy, as a curative agent, of intercourse on the part of a diseased male with a virgin, and unable to trace this dangerous belief or prejudice to any tangible antecedent or cause, I am inclined to bring the matter to the notice of your readers through these pages, and to ask you to allow me to solicit the favour of their attention to it. Many years ago, while working a parish in Westminster, or, later on, when engaged as house-surgeon to a metropolitan hospital, I became aware of the fact that many young girls were infected in this way, or through this mistaken expectation. Instances have even come under my notice wherein sisters were so abused by their venereal-ised brothers; and though this myth or superstition can scarcely claim the same antiquity or universality as belong undoubtedly to the stories of Jason and the Golden Fleece, Cinderella and her Slipper, or even of Whittington and his Cat, yet has it attained a considerable prominence, and its influence for evil is, I think, much greater than is generally supposed. Further, having failed in all my endeavours to connect it with the old feudal institution or usage that was called in this country the *jus primæ noctis* and in France *Les droits de la première nuit*, I turned to such books on the history of the Middle Ages, or on Forensic Medicine, as came casually in my way, but to no purpose; and the subject is one which could scarcely be taken up in the lay press.

Some weeks ago, when on duty at Chester, I strolled into the Court House, which is situated in the Castle there, just as the jury in a case of rape had retired to consider its verdict. The defendant in the action, a lad of some nineteen or twenty summers, though he looked much younger, had, it was alleged, infected a little girl, or rather what appeared to be an overgrown child, who had been put to bed with him, for some domestic reason or other that did not transpire, in this way, and the imputation or assumption was that he had forcibly violated her. She said as much herself, and she bore unmistakeable evidence of violence and disease on her person. Her assailant was proved to be suffering from a gonorrhœa at this time, and there was no other known medium or means through which the girl could contract it. The jury found him guilty of the offence, but recommended him to mercy, chiefly, as I understood the foreman to say, that no female, however young she may be, ought to have been placed in the same bed with a boy of his age; and secondly, because he was shown by his counsel and others to have been influenced in his actions towards her by this belief or expectation. Mr. Justice Grove, who tried the case, and who is, as everybody knows, a very learned man, took this recommendation into account, and reducing the crime from thecategory of a felony to that of a misdemeanour, awarded him eighteen months' imprisonment with hard labour. He at the same time characterised this belief or superstition as "a vile and abominable one," but he did not combat or even try to discredit it, and I inferred from his language that it was one of common acceptance in these parts. I believe, in short, that the hope of an easy and speedy relief from a troublesome and tedious malady that this belief holds out acts as a direct incentive to the commission of rape in country districts, and there can be no reasonable doubt at all as to its wide-spread diffusion and popularity. Equally self-evident is the fact that it must, like other beliefs of the same kind, have some foundation in the history or practice of the past, but what that foundation is I am, for the reasons above given, unable to say, and I shall be glad to receive any or such communications on the point as your readers may be pleased to address to me.

Having read, some months ago, in India, a statement in a historical grave work—to wit, "The History of the Royal Sappers and Miners"—to the effect that an insane soldier of that corps had been actually put to death by suffocation, and finding that a belief in the existence and legality of such a process did also formerly obtain, I am inclined to advert to it here, and ask for such a summary of the evidence of the circumstance as may be now available. The passage runs as follows, and whatever complexion this belief may have formerly worn or assumed in England, there is no doubt in my mind that I used to hear of it, during my boyhood, in Ireland, and that is my principal reason for calling attention to it in the pages of this journal. Alluding, then, to the hopeless lunacy of one of his old comrades, Mr. Conolly says (vol. i., page 20.):—"Soon afterwards he was domiciled in a mad-house, where, his malady increasing, he was—it was then reported—smothered, according to the cruel practice then in vogue with regard to incurable cases;" and I have been as unsuccessful in my search after the truth in this case as I was in the foregoing instance. I question very much, however, whether any authentic example or illustration of this practice can be found within, say, the last hundred years or so in these islands; but I may be wrong, and in either case I shall be grateful for any or such light as the courtesy or erudition of your readers may be able to throw on it.

Alluding to the barbarous treatment employed for hydrophobia in Ireland in his day—*circiter anno* 1781—and after mentioning that "Such a dread had the Irish of the bite of a mad dog that they did not regard it as murder, but absolutely as a legal and meritorious act, to smother any person who had arrived at an advanced stage of that disorder, if he made a noise similar to barking his hour of suffocation was seldom protracted." Sir Jonah Barrington gives an illustration in point in his "Personal Sketches of His Own Times" (Routledge's Ed., vol. ii., pp. 203-7) which I will condense to the utmost to save space. Describing a friendly dinner which he partook of at the house of a magistrate in the Queen's County in the year named above, Sir Jonah proceeds to say that "We had scarcely finished dinner when a crowd came up to the door in great confusion and asked humbly to speak to his worship.

"Tom Palmer seemed to anticipate their business, and inquired at once if Dan Dempsey of the Pike was in the same way still?

"Twenty voices responded together 'Worse, your worship, worse nor ever; death's crawling up him; he can't *stop*, and what's the use in leaving the poor boy in his pains any longer, your worship? We have got two good feather beds at the Pike,' &c. . . . . .

"'Come in, then, any three of you who can clearly swear Dan Dempsey barks like a dog.' The selection was accordingly made, and the affidavit . . . . sworn . . . . Squire Palmer then directed them to go back to the Pike, and said they might smother Dan Dempsey, if he barked any more, in the morning, but told them to wait till then.

"The magistrate's directions were accurately obeyed. Daniel barked, and was duly smothered between two feather beds three hours after daybreak next morning by the schoolmaster's watch." He adds further on, p. 208, that "the matter was not at that day considered the least extraordinary, and was, in fact, never mentioned except in the course of common conversation, or as the subject of a paragragh in a local paper;" and I was myself quite familiar with the existence of this belief, farther south, many years later.

Mead is the only other writer who alludes to this measure, as far as I know, but he does so deprecatingly, or by way of contrast, and he implies that it was not unknown in England. But we will let him speak for himself; and I will only here add, on my own behalf, that barbarous as this proceeding undoubtedly was, it yet had some redeeming feature. It was, at least, more merciful, inasmuch as it was more speedy than many of the other cures and expedients that were then resorted to. But to the point. "At least," says our author ("On Poisons," p. 177), "there is more humanity in such a proceeding (forcible immersion, or rather submersion) than in stifling a miserable wretch between two feather beds, which, as I am informed, is the practice in a neighbouring country, *and sometimes in our*

Digitized by Google

own." (The italics are mine.) Mead's testimony admits of no question. Not so, perhaps, that of Sir Jonah, who enjoyed, in his day, the somewhat doubtful repute of not being particular as to the manner in which he manipulated his facts. He was also said, though I believe unjustly, to have so exaggerated some ordinary colloquial phrases as that they assumed the dimension of grave historical statements, and he certainly invested some of his own personal adventures with an importance they did not deserve. But his style was attractive, his stories were amusing, and he raised a plain country gentleman, named Boyle Roche, to an almost equal pedestal with some of Shakespeares minor creations. He did more. Though a poor man, he resisted the corruption of the time, and retained his independence in what Macauldy has called the most corrupt assembly in the world—the Irish House of Commons. This is high praise, and I will not lightly believe that the man who could so demean himself in such an age would descend to the level of a hypocrite or a liar.

I am, Sir, your very obedient servant,

WM. CURRAN,
Surgeon-Major, A.M.D.

Warrington, December 2, 1879.

ARSENIC.

WHAT is the chemical cause of the poisonous properties of arsenic? Liebig at one time offered a theory on the subject, to the effect that arsenious acid and corrosive sublimate have in very high degree the power of forming solid combinations with albumen, and, when taken internally, they thus render the albumen of living tissue incapable of undergoing the transformations necessary to it, simply extinguishing the life of important parts. This view, however, though it still appears in some handbooks, Liebig gave up. In a recent note on this question to the Berlin Chemical Society, MM. Binz and Schulz point out that, in arsenic poisoning, it is precisely those tissues which are specially adapted to absorb and work up the *oxygen* of the blood (especially the protoplasm glands) that are the seat of the destruction. Now arsenious acid can easily be changed into arsenic acid, while arsenic acid is transformed still more easily into the other. The latter process is effected by albumen generally, the former by *living* albumen of animals and plants. From various experiments, the authors conclude that by reason of this transformation of the two acids into each other within the living albumen-molecule, causing a vigorous to-and-fro displacement of the oxygen atoms, the tissues are corroded and completely destroyed. Between arsenic and nitrogen there is an exact parallel in this respect. Nitrous oxide is very poisonous. By taking up oxygen, it is changed into the violently-oxidising hyponitric acid. It destroys the tissues, while, by taking up water, it can be partly transformed again into nitrous oxide. In the whole process, the nitrogen has no direct action; it is merely the inert carrier and distributor of the active oxygen atoms. The same *rôle* is played by arsenic as a carrier of active oxygen, *i.e*, there is a constant change going on from arsenious to arsenic acid.

POISONS AND ANTIDOTES.

IN an interesting article on this subject, by Dr. F. A. Falck, which we find referred to in Schmidt's *Jahrbücher* the writer points out that the so-called antagonism of opium and belladonna was noticed by Albinus and others as early as 1570. A real antagonism does not exist, according to Falck. His conclusions are as follows:—

1. Atropin is a true antidote for muscarin; but not the latter for the former.
2. Duboisin is also a true antidote for muscarin.
3. Atropin and duboisin are also antagonistic to pilocarpin.

Atropin and physostigmin,
Strychnin and chloral hydrate,
Chloral hydrate and atropin,
Morphine and atropin,

Are all respectively antidotal in a pharmacological sense, but not in a physiological one. That is, the one will diminish the symptoms caused by the other, but will not produce contrary physiological effects.

Medical News.

Royal College of Surgeons in Ireland.—At the examinations held Dec. 8th, and following days, the undernamed gentlemen passed their final examination, and were admitted licentiates of this College, viz.:—Robert Allman, John Richard Baker, Charles James Barry, James Henry Beattie, Robert Ettingsall Beatty, Charles Matthew Brady, Hubert Watson Brownrigg, Chas. Hayden Cox, James Davison, Mathew Digan, George Digby, George Phillip Elliott, Hubert Flanagan, John Gray, Arthur Greene, Arthur Robert Harper, Thomas Higgins, John Anderson Irwin, L'Estrange Isdell, James Kernan, Anthony Kidd, Patrick Joseph Lenihan, John Stephen M'Ardell, John M'Cullagh, John M'Loughlin, George Alexander Montgomery, Charles George Drummond Moss, John Murphy, Thomas Joseph O'Donnell, James Joseph O'Dwyer, John Pollock, William James Swanson, John Whittaker Tate, William Augustus West, Edward de Lacy Wickham, and John Wilson.

Association of Surgeons Practising Dental Surgery.—The annual general meeting of this Association for the election of the Officers and Council for the ensuing year, and for transacting the usual business, will be held on Wednesday, January the 28th, at 4.30 p.m. The following is a list of the names of Fellows proposed by the Council as Officers for 1880:—President: *Mr. W. A. N. Catlin. Vice-Presidents: Mr. J. A. Baker, Mr. Samuel Cartwright, Mr. Alfred Coleman, Dr. John Smith, F.R.S., *Mr. S. J. A. Salter, F.R.S. Treasurer: Mr. T. Edgelow. Hon Secretary: Mr. J. Hamilton Craigie. Council: *Mr. Edward Bartlett, Mr. S. H. Cartwright, Mr. J. Fairbank, Mr. F. Fox, Mr. W. Donald Napier, Mr. George Parkinson, Mr. W. G. Ranger, *Mr. Augustus Winterbottom.—An asterisk is prefixed to the names of those not holding the same office the preceding year. The Fellows of the Society and their friends will dine together in the evening at the Langham Hotel, at seven o'clock.

Bandaging the Infant.—As evidence in favour of dispensing with bandaging infants at birth, Dr. Langworthy, of Louisiana, writes that of late years he has entirely abandoned this ancient ceremony, and that in the now very large number of cases where he has not applied the bandage not one gave any subsequent trouble, so far as the condition of the umbilicus was concerned. In one or more cases which he can recall, he is of opinion that fatal attacks of trismus nascentium were directly due to the bandaging.

Origin of Plants.—Cabbage grew wild in Siberia; buckwheat originated in Siberia; celery originated in Germany; the potato is a native of Peru; the onion originated in Egypt; tobacco is a native of South America; millet was first discovered in India; the nettle is a native of Europe; the citron is a native of Asia; oats originated in North Africa; rye came originally from Siberia; paraley was first discovered in Sardinia; the parsnip is a native of Arabia; the sun-flower was brought from Peru; spinach was first cultivated in Arabia; the pear and apple are from Europe; the horse-chestnut is a native of Thibet; the quince came from Island of Crete; the radish is a native of China and Japan; the pear is supposed to be of Egyptian origin; the horse-radish came from the south of Europe.—*Chicago Med. Jour.*

NOTICES TO CORRESPONDENTS.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the MEDICAL PRESS AND CIRCULAR, can now be had at either office of this Journal, price 2s. 6d. The postal regulations not allowing the Journal to be stitched, these cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

Digitized by Google

DR. PANTALEONI, Rome.—Your letter will appear, if possible, in our next.

THE INDEX for the present volume will be given in our next.

DR. PEARSE, Plymouth.—Probably in our next.

SURGICAL SOCIETY OF IRELAND.—The Report of this Society reached us too late for insertion in present number.

DR. T. F. WOOD, Wilmington, U.S.A.—The remaining papers on "Syphilitic Urethritis," by Dr. Chas. Drysdale, will appear as soon as space permits.

PROF. LISTER and DR. ALEX. STEWART are thanked.

A PENNY POSTAGE STAMP OF A NEW DESIGN will shortly be issued. It is similar in its general features to the present stamp; the colour, however, is of a paler red. As the stamp is printed on thinner paper than that hitherto used, and as the gum is of a better kind, it will adhere more readily and securely to the letters. Some time may elapse before the stock of the present stamps is exhausted, so that both the old and the new stamps will be in circulation concurrently.

A NEW VIEW OF SMALL-POX.—On Christmas Day a letter appeared in the columns of the *Times* in which the writer, in very pompous and dictatorial language, calls upon the Legislature to at once repeal the Vaccination Act, to hang all opposing doctors and followers of "the half-witted Jenner," and all others to consider Mr. Ward as the new light in matters medical and vaccination in particular. We can only express our surprise that the Editor of the first newspaper in the world should have passed such a mad-brained effusion. Since then we have received a post-card from Mr. Morrison, of pill notoriety, stating that Mr. Ward's new theory !!! is not his at all, "having been proclaimed by the British College of Health (Morrison's Pill-making Establishment) for the last fifty years." Poor deluded Mr. Ward!

DOUBTFUL PRESCRIPTIONS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Enclosed prescriptions are from the pen of a dispensary physician, and have been compounded by the resident apothecary. As a matter of curiosity I should like to have your opinion as to their pharmaceutical accuracy. Please observe that in the compounding of that marked I. combustion ensues with the evolution of actual fire.

I am, &c.,

E. H. C.

No. I.

℞ Argent. oxyd., gr. vi.;
Acid carbolic, gr. vi.;
Pulv. opii, gr. iij.;
In pil., xij.

[*** This prescription might well excite the curiosity of our correspondent. Still, had he taken the trouble to refer to "Squire's Companion to the Pharmacopœia," 11th edit., page 51, he would have found that argenti oxidum, when prepared with creasote or similar substances, would take fire on being put together; and we presume the same thing would occur in regard to carbolic acid. We do not think it worth while to occupy our space with the other prescriptions, as Nos. III. and IV. are perfectly correct, and No. II. errs only on the score of maximum doses of croton-oil and castor-oil being combined, which is certainly a little unusual, but nothing beyond this.—ED.]

HARVEIAN SOCIETY OF LONDON.—Thursday, Jan. 8, at 8.30 p.m., Anniversary Meeting and Election of Officers.—President's Address.—Conversazione.

THE METRIC SYSTEM.

As we are frequently asked for information on the metric system, we shall publish the annexed and other tables from time to time, with the view of assisting our readers in what is rapidly becoming a difficulty, in consequence of the frequent use of the metric notation by writers, both in our own and other journals:—

METRIC MEASURES OF LENGTH.

Millimetre	0·001	of a Metre	equals	0·03937	inch
Centimetre	0·01	,,	,,	0·39370	,,
Decimetre	0·1	,,	,,	3·93707	,,
METRE	1	METRE	,,	39·37079	inches
Decametre	10	Metres	,,	393·70790	,,
Hectometre	100	,,	,,	3937·07900	,,
Kilometre	1000	,,	,,	39370·79000	,, (1 mile)
5 Kilometres	..	...	equals 3 miles		

METRIC MEASURES OF WEIGHT.

Milligramme	0·001	of a gramme	equals	0·015	grain
Centigramme	0·01	,,	,,	0·154	,,
Decigramme	0·1	,,	,,	1·543	,,
GRAMME	1	GRAMME	,,	15·432	grains
Decagramme	10	Grammes	,,	154·323	,,
Hectogramme	100	,,	,,	1543·234	,,
Kilogramme	1000	,,	,,	15432·348	,,

454 Grammes equal to 1 lb.

METRIC FLUID MEASURES.

When using the metric system, fluids are preferably prescribed by weight, employing the gramme, its multiples and sub-divisions, just the same as with solids, thus avoiding the errors due to refraction, adhesion, and inaccurate measuring vessels.

For practical purposes, four grammes of water may be regarded as equivalent to a fluid drachm of that liquid. And the same may be considered true of tinctures and infusions. Syrups, on the average, are about one-third heavier than water, so that a fluid ounce of a syrup will be approximately represented by 33 grammes. Fluids may be prescribed by volume in the metric, just as in the present system, using for that purpose the cubic centimetre, that is a volume represented by a cube, all of whose sides measure one centimetre.

One cubic centimetre (C.C.) equals 16·231 minims. It is approximately regarded as one-fourth of a fluid drachm.

Mem.—Approximate weights of 20 drops of the following:—

	GRAMMES.	GRAINS.
Ether Sulphuric at 66 deg.	0·35 equal to	5½
Liq. Hoffman	0·45 ,,	6¾
Alcohol at 80 deg.	0·45 ,,	6¾
Oil of Almonds	0·55 ,,	8¼
Acid Acetic at 10 deg.	0·60 ,,	9
Essential Oil of Peppermint	0·65 ,,	9¾
Distilled Water	0·75 ,,	11¼
Laudanum	0·70 ,,	11
Acid Sulphuric, 60 deg.	1·20 ,,	17½
Syrups at 35 deg.	1·50 ,,	23

VACANCIES.

Bedford Infirmary.—Resident Surgeon. Salary, £100, with board. Applications to the Secretary before Jan. 20.

Brompton Consumption Hospital.—Dental Surgeon. Honorary. Applications to the Secretary by Jan. 7.

Drogheda Union, Stamullen Dispensary.—Medical Officer. Salary, £110, with fees, and £20 as Sanitary Officer. Election, Jan. 12.

Killarney Union, Coom Dispensary.—Medical Officer. Salary, £100, with fees, and Sanitary salary. Election, Jan. 2.

London Hospital Medical College.—Warden and Secretary. Emoluments amount to between £300 and £350. Applications to the Acting Secretary before Jan. 5.

Manchester, Hospital for Sick Children at Pendlebury.—A Senior and a Junior Resident Medical Officer. Salary, £100 and £80 respectively, with board. Applications to the Chairman of the Medical Board before Jan. 4.

South Molton Union.—Medical Officer of Health. Salary, £130. Applications to the Clerk of the Guardians South Molton, before Jan. 9.

Sunderland Infirmary.—Physician. Honorary. Applications to the Secretary before Jan. 28.

St. Bartholomew's Hospital, London.—Assistant Surgeon on the Staff. Applications to the Clerk before Jan. 5.

Thurles Union, Templemore Dispensary.—Medical Officer. Salary, £100, with fees, and £10 as Sanitary Officer. Election, Jan. 14.

APPOINTMENTS.

FULTON, T., M.D., L.R.C.S.Ed., Certifying Factory Surgeon for the District of Saintland, co. Down.

HALL, J. C., M.B., Medical Officer to the Monaghan Union Workhouse.

HOLLIS, A. A., M.D., Medical Officer and Medical Officer of Health for the Yarmouth District of the Isle of Wight Union.

JOHNSON, C. H., M.R.C.S.E., Medical Officer to the Basingstoke Union Workhouse.

LENDON, A. A., M.B., House Surgeon to the Bristol Royal Infirmary.

LYON, F. H., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer for the No. 3 District of the Newbury Union, Berks.
